Half-yearly Abstract of the Medical Sciences (Review), 72
Harveian Society, Anniversary Meeting, 37
Health of the Prussian Army, 262
Heart Diseases, the Symptoms, Pathology, and Treatment of, 5, 79, 163, 227, 259, 327, 391
Heart, Rupture of the, 354
Hereditary Influence, Considerations with Regard to, 123
High Death-rate in the Metropolis, 64
Hippocrates, the Life of, 45
Home Nurse, the, and Manual of the Sick Room (Review), 285

HOSPITAL REPORTS:
Amaurosis supervened on Eight Successive Parturient Periods, Abstract of a Case in which, 164
Hard Tumour of the Left Breast, Operation for, 21
Notes on some of the Cases under Dr. Greenhalgh, 195, 212
Varicocele, Operation and Cure, 60, 80
Vascular Tumour of the Meatus Urinarius, Cases of. (Under the care of Mr. Shillitoe, Surgeon to the Lock Hospital), 276
EDINBURGH ROYAL INFIRMARY:
Cardiac Neuroses, Observations on, in Prof. Laycock's Wards, 115
KING'S COLLEGE:
Amputation below the Knee-joint, 346
Ankle-joint Disease, 346
Calculus, Extraction of, 392
Cleft in the Soft Palate, attended with Slight Deficiency of the Hard, 329
Cleft Palate, 269, 392
Congenital Hernia, Operation for Radical Cure, 329
Deficiency of the Anterior Wall of the Abdomen remedied by Operation, 228
Encysted or Ovarian Dropsy, combined with a Firm Solid Tumour in the Pelvis, 293
Fistula in Ano, Operation, 245
Fungus Hematodes of the Palm of the Hand, 293
Lithotrity for the Third Time in a Middle-aged Subject, 345
Hip Disease, 329
Nævus, Operation for, 312, 392
Necrosis of the Humerus, the Result of Fracture, 329
Necrosis of the lower Part of the Shaft of the Femur, and Removal of the Dead Bone, 294
Necrosis of the Metatarsal Bone of Great Toe, 294
Oblique Inguinal Hernia, 425
Secondary Amputation for the Re-fashioning of a Bad Stump, 347
Sequestrum of Bone removed from Thumb of Right Hand, 292
Urethral Fistula, 292
Stone in the Bladder, Lithotomy, 329
Strangulated Hernia—Stricture of the Rectum—Stricture of Urethra—Indurated Patellary Bursa, under the care of Mr. Henry Smith.—Stricture of the Rectum—Double Psoas Abscess, accompanied with Curvature of the Spine and Vertebral Disease—Umbilical Hernia in Adult Male—Inguinal Hernia of the Left Side, under the care of Mr. Wood, 408—410
MIDDLESEX HOSPITAL:
Eccentric Epilepsy, 99
Inflammation of the Sac of Fibrous Tumour, 180
Ovarian Tumour, Case of, 180
Polypus Uteri, Case of, 294
Umbilical Hernia of Large Size, 99
ROYAL ORTHOPÆDIC:
Division of the Flexor Tendons, 101
ST. BARTHOLOMEW'S:
Notes on Cases under Dr. Greenhalgh, 195, 212
UNIVERSITY COLLEGE:
Cancerous Deposit at the Angle of Junction of the Corono-glandis and the Prepuce, 44
Cases under the care of Mr. Erichsen, 100
Concussion of the Brain, 393
Diseases of the Finger-joints, 62.
Oblique Inguinal Hernia of Right Side, 43
Sub-coracoid Dislocation of the Humerus, 63

[*From the Case-Book of* GEORGE JOHNSON, ESQ., M.D., *Physician to King's College Hospital, Professor of Medicine in King's College.*]

THE PRACTICAL VALUE OF RHINOSCOPY.—CASE OF A CYST OBSTRUCTING THE POSTERIOR OPENING OF THE RIGHT NASAL FOSSA.

Professor Czermak, when he was in London last summer, told me that the main object which he had in view during this last visit was to give an impulse to the study and practice of rhinoscopy. Laryngoscopy, he knew, was appreciated by us as it deserved to be, but he thought that the comparatively unattractive and difficult art of rhinoscopy had received too little attention. Impressed by these remarks of my friend and teacher, I determined, in future, to pay more heed to this invention of his, and the following case affords a good illustration of its value.

I may take this opportunity of remarking that I have found a round glass mirror about the size of a sixpence far better than the small steel mirrors which are usually made for rhinoscopy. The chief objection to the steel mirror is the rapidity with which it cools and consequently becomes dimmed by the patient's breath. I may observe, too, that I am more than ever convinced that in the practice of both laryngoscopy and rhinoscopy the reflector should be fixed on the *forehead* and not in front of one eye. The latter position is attended with no advantage, that I can discover, in the mode of illumination, while its disadvantages and inconveniences are obvious and indisputable. (See two papers by the Author, 'Medical Times and Gazette,' Feb. 14, 1863, and June 6, 1863).

CASE.—*Gradually increasing and at length complete obstruction of the right nostril. Rhinoscopic examination discovers a globular tumour filling the posterior opening of the nasal fossa. The tumour, removed by forceps, proves to be a cyst containing a glairy fluid. Cure.*

Mr. J—, æt. twenty-four, about two years ago, after a severe cold, began to experience some difficulty in drawing air through the right nostril; this difficulty continued and steadily increased until at the end of about a year the obstruction was complete. During the last year he has been unable, by any effort, either to inspire or to expel air through the right nostril. The left nostril remains pervious, but, in consequence of the obstruction on the right side, the patient habitually keeps his mouth open; respiration being impeded when the mouth is shut. The voice has somewhat of a nasal character. There has been no unusual discharge from the nostril. Examination of the nostril in front discovers no obstruction. The mucous membrane appears quite healthy, nor is any abnormal appearance visible on examination of the palate and pharynx in the ordinary way through the open mouth. Rather more than a year ago he consulted an eminent surgeon who probed the nostril without discovering the seat or cause of the obstruction. He has consulted me occasionally during the past year. I prescribed various remedies; he has twice gone into the country for rest and change of air, but while his general health and strength have improved the nasal obstruction and its attendant annoyances remain the same.

In the early part of December, on his again consulting me, I determined to make a rhinoscopic examination. He has a throat favourable for rhinoscopy; a small uvula, with the soft palate at some distance from the back of the pharynx, so that a small mirror can be introduced obliquely beneath and behind the soft palate, and it is unnecessary to draw the uvula and palate forwards. I soon obtained a complete view of the posterior nares. The left nostril was found quite normal; the right was seen to be completely obstructed by a tumour of apparently globular form, having a slightly granular surface, and a yellowish green colour. It touched the floor and the septum of the nose; and, externally it pressed upon and concealed the turbinated bones. By means of a probe, bent like a shepherd's crook, and introduced below and behind the palate, I succeeded in touching the surface of the tumour, while I saw it in the mirror; it had a soft, but somewhat elastic feel. I concluded that the tumour was a polypus, and I now asked my friend and colleague, Mr. John Wood, to examine the patient with me, and to devise a plan for removing the tumour. He at once saw the tumour in the mirror, and made a sketch, which gives a correct representation of the appearance presented by the posterior nares. (See woodcut, Fig. I.)

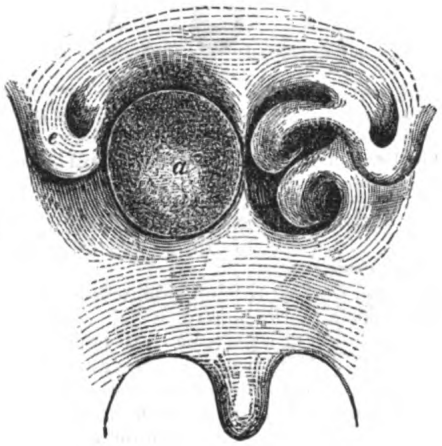

FIG. I. Posterior view of uvula, soft palate, and nares, as seen in the mirror. The tumour *a* on the left of the figure fills up the posterior opening of the right nasal fossa; *e*, the orifice of the right Eustachian tube.

On probing the nostril he found, as I had done before, that while the probe readily passed through the left nostril backwards, a soft obstruction was felt at the back of the right.

On the 23rd Dec., Mr. Wood, in the presence of Dr. Yearsley and myself, introduced a slender curved polypus forceps through the anterior opening of the nostril, grasped the tumour, and as he was drawing it forwards there was a sudden rush of a glairy fluid, like white of egg, and some membranous shreds came away between the blades of the forceps. The patient could now readily blow through the right nostril; and on rhinoscopic examination the nostril was seen to be pervious. The tumour had disappeared, the turbinated bones were plainly visible, and on the under side of the middle turbinated bone there was an abraded surface, from which apparently the tumour had been torn (see woodcut, Fig. II.) The tumour evidently had not been a solid polypus, as we had supposed, but a hollow, globular cyst, containing fluid. This was burst by the forceps, and now not a trace of it remains. On the second day after the operation, a portion of the cyst-wall came away, this I have preserved; it is smooth on its inner concave surface, but uneven on the outer surface, by which, apparently, it had been attached to the mucous membrane. During the first few days after the operation, the abraded surface (indicated at *a*, Fig. II.) was covered by a purulent secretion; this has now healed over. The mucous membrane appears quite healthy. The patient has lost all sense of obstruction in the nostril; he can breathe comfortably with the mouth closed, and the voice has recovered its natural tone.

The practical value of rhinoscopy in this case can scarcely be called in question. It is doubtful whether by any other method of exploration the position and nature of the

tumour could have been determined with sufficient certainty to warrant an operation for its removal.

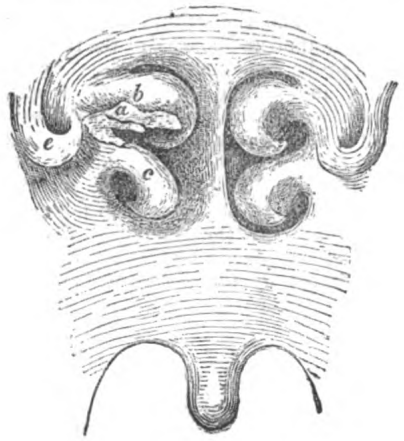

FIG. II. The posterior nares after the removal of the tumour; *a*. The abraded surface from which the tumour was torn. *b*. The middle, and *c*, the inferior turbinated bone. *e*. The Eustachian tube.

Czermak, in the last edition of his work,* gives a good illustration of the value of rhinoscopy in correcting an erroneous diagnosis.

A young man, deaf on the left side, was found to have a tumour at the back of the nostril which conveyed to the finger the impression of a polypus. An operation was contemplated, but a rhinoscopic examination discovered a tapering swelling of the mucous membrane, nearly as thick as the finger, surrounding the orifice of the left Eustachian tube, also great swelling of the middle and inferior turbinated bones, but no polypus nor any tumour which an operation could have removed or lessened.

From the Case-Book of BARNARD HOLT, ESQ., *Senior Surgeon to the Westminster Hospital, &c. &c.*]

CASES ILLUSTRATIVE OF THE BENEFITS TO BE DERIVED FROM THE EMPLOYMENT OF THE STRICTURE DILATOR IN THE TREATMENT OF STRICTURE OF THE URETHRA.

Mr. A—— was sent to me from from Shanghai, suffering from stricture of the urethra, of a painful and somewhat complicated kind. He informed me that for a considerable period he had experienced difficulty in micturition, and that he had been the subject of several attacks of retention of urine, that it was usual for him to pass water frequently during the day, and that after riding he suffered intense pain, so as to compel him to assume the recumbent posture. Many and frequent attempts had been made to increase the diameter of the urethra, but without success, and after very prolonged treatment, it was found to be impossible to pass a larger instrument than No. 3, and as each attempt was followed by severe suffering, he had been advised to come to England, and place himself under my care. Upon examination, I found he had a tight elastic stricture in front and another behind the bulb, which after some difficulty admitted a No. 3 catheter, grasping it with great tenacity, and rendering it somewhat difficult to remove; there was no bleeding, but the introduction gave him pain, and he informed me he always passed water with great difficulty after the passage of a bougie. Having taken his abode in my immediate neighbourhood, I in a we after his first consulting me, introduced the dilator and once split the strictures with the No. 12 tube, substituti a catheter of that size simply for the purpose of removi the urine; he did not make the least complaint when t tube was passed, and assured me the pain of the operati was infinitely less than he had suffered from the small theter. As he was somewhat out of health, and in order prevent any rigor, I passed the catheter again in four hou and withdrew the urine; this was repeated on each day four days, and then on every subsequent day for a fortnig at the expiration of which time he was taught to pass t bougie for himself, which he effected with the greatest ea This gentlemen never had a bad symptom of any ki whatsoever, he was out the day following the operation a in less than three weeks was perfect master of his ca passing his own No. 12 with the greatest ease, and to u his own words, "making water as well as he ever did his life."

Mr. T—— was sent to me by a surgeon at Ramsgate, consequence of his being the subject of an obstinate stri ture of the urethra, which had defied the efforts of his ow surgeon to pass any instrument into his bladder. He cor plained of the usual train of symptoms, and, in additio that the stricture was so irritable as to bleed upon eve occasion that a bougie was attempted. After some difficul I succeeded in introducing a No. 3, and on the third da following passed the dilator and the No. 12 tube. Althoug he was a highly nervous sensitive person, he never co plained of the least pain from the operation, and in o week returned to Ramsgate, passing his water in a fu stream, and capable of introducing his own No. 12, whic he did in my presence before leaving London.

Mr. W——, a merchant of Liverpool, consulted me f obstinate stricture of the urethra, from which he had bee suffering for sixteen years. His chief complaint was fr quency and great straining in passing water, a dull, heav aching in the perinæum, turbid and mucoid urine, an great irritability of the urethra after the passage of catheter, so that for many days succeeding each introdu tion, the urine passed slowly, and in a very fine stream. No. 3 catheter could be introduced without material diff culty, but it was firmly grasped and required some force remove it. Having made arrangements to be near me f a week I passed the dilator, and split the obstruction with t No. 12 tube, the urine was at once removed with the No. catheter, and again in four hours by the same means, assures me that the pain was momentary and trifling; the was the slightest possible bleeding, not amounting to a te spoonful. This gentleman, like the others, never had t slightest bad symptom, he resumed his business on the f lowing day, and in ten days from the operation return to Liverpool, having been taught to pass his own No. 1 and making water as free as he ever did.

The above cases, although not types of stricture of gr severity, yet were of a class that rendered the tre ment by ordinary dilatation almost useless, the str ture being of that nature which would allow its to be dilated to No. 4, but no further, and wh speedily contracted so soon as the passage of t catheter was abandoned for even a week. It will be noti that in neither case was there rigor or inconvenience of a kind; and this I believe my more extended experie enables me to state is attributable to the removal of urine from the first twice after the operation, for in no c has there been the slightest inconvenience of any ki whether fever, rigor, retention, or any complication. T following is a case of a more obstinate kind, and afford still more striking illustration of the benefit to be deri from this method of treatment. Mr. ——, a patient of Cleveland, of Maida Vale, consulted me, by Dr. Clevela advice, in consequence of an old resisting stricture, wh had defied the introduction of a catheter for two years, a which was rapidly becoming worse. The patient, a gen man thirty-seven years of age, had for many years been subject of stricture; four years since Dr. Cleveland s

* Der Kehlkopfspiegel und seine Verwethung für Physiologie und Medizin, p. 127-8. Leipzic, 1863.

ceeded in dilating the urethra so that the stricture would admit a No. 8, his patient, however, subsequently neglected the treatment, and in two years afterwards it was found to be impossible to pass any instrument beyond the first stricture situated in front of the bulb.

Upon seeing the patient, I found him pale, with a feeble heart somewhat out of health, and making water only by great straining in a very small stream, and frequently by drops. I failed in passing even the smallest catheter, for although I could succeed in entangling the point in the second obstruction, I could not penetrate it. Upon my second visit, after an interval of a day, I succeeded after a prolonged trial, and with great difficulty in passing a No. 1 through three strictures into the bladder, and as there had been so much difficulty in introducing it, I determined to retain it by fixing it to the penis. On the following day the catheter had become somewhat loosened, and upon its removal, and with great difficulty, I succeeded in passing the dilator and splitting the stricture, with the No. 12 tube, although from the patient shrinking at the time the tube was thrust forwards, they were not so effectually split as I should have desired; a No. 9 catheter was passed to remove the urine. In four hours after a catheter was again passed, upon the principle I have already mentioned, to prevent any rigor, and on the following and first three days a catheter was introduced once daily; in less than a week No. 11 could be passed with facility, he never had the semblance of a bad symptom, and is progressing uninterruptedly well.

Mr. Ambler, of Hemel Hempstead, requested me at my monthly visit to the Hemel Hempstead hospital, to see a young man, a shoe-maker, who had suffered from stricture for many years; he had been frequently the subject of retention of urine, and on more than one occasion had infiltration and abscess, of which there was ample evidence in his indurated and perforated perinæum fistulæ existing, through which the urine escaped. *No instrument had ever been passed into his bladder*, although numerous attempts had been made over a series of years. Upon examination I found a hard cartilaginous obstruction at the bulb, through which, with great difficulty, I was enabled to pass a No. 1 catheter. It was, however, arrested at a membranous part, but after considerable perseverance I succeeded in passing the catheter into the bladder, the eye of the catheter became blocked with blood, and some doubt was expressed by one surgeon as to the catheter having reached the bladder. The case being one of considerable severity and complication, I advised his removal to the Westminster Hospital. Between the time of my seeing him at Hemel Hempstead and his removal to the Hospital another abscess had formed, and was opened shortly after his arrival, and gave him some relief; retention of urine, however, supervened, and he was placed under the influence of opium, which enabled him after some time to pass a small quantity of urine; in a few days he was somewhat more easy, and upon my second attempt I succeeded, after great difficulty, in passing a No. 1 catheter, and removing the contents of the bladder, together with a considerable quantity of pus, evidently from an abscess in the prostate; this catheter was fastened in, and on the following day, although he was much exhausted, I passed the dilator, split the obstructions, and introduced a No. 10 catheter with ease. A considerable quantity of pus escaped after the urine was removed, the catheter was passed a second and a third time during the day and night, but although it entered the bladder with the greatest ease, the patient was unable on the following day to relieve himself, the catheter was therefore again had recourse to. A further report upon this case will be forwarded in a short time. The case is interesting, 1st, from the fact of a catheter never having been introduced into the bladder; and, 2nd, that the operation was performed with perfect impunity, although the patient was at the time the subject of abscess in the prostate, and many fistulæ in perinæa.

SMALL-POX IN MADRAS.—From a recent return it appears that the deaths from small-pox in the Madras Presidency amount to 20,000 annually.

[*From the Case-Book of* JAS. YEARSLEY, ESQ., M.D.]

ON THE REMOVAL OF EXUBERANT GROWTHS OF THE TONSILS AS A REMEDY FOR IMPERFECT HEALTH IN YOUNG PERSONS.

Twenty years ago he would have been a bold man who would have ventured to express an opinion and act upon it as an axiom, as I have done for many years, that the tonsils in a permanently enlarged and indurated state—in other words, in a diseased state—should be removed. It is a well known fact that for that long period, and even longer, I have advocated such treatment in cases of deafness, and on the first announcement of my opinions, I suffered no little opprobrium for my zeal in pressing forward the practice, but it was at the hands of those who either did not or would not understand the rationale of the treatment. Without further recurring to the past, or resuscitating the many most absurd utterances of some of my contemporaries on this subject, such as loss of voice, wasting of the mammæ and other distant glands, as consequences of removing the exuberant growths of tonsils, *for be it remembered the tonsils themselves are never wholly removed*, I am going to astonish these worthies, and it may be many others, by recommending, as the result of an immense experience, that in all cases, and wherever enlarged tonsils exist, the morbid growths should be at once removed. There may be no deafness, there may be no muffled voice, no direct manifestation of functional derangement, but in the vast majority of cases there will be an evident deterioration of the general health and bodily vigour, which will be found to arise wholly and solely from enlarged tonsils. Paterfamilias may be heard to say, "I don't know what is the matter with my son, Tom, but he does not seem to thrive like the other children; he ought to be an inch taller and a stone heavier than he is, and yet he eats, drinks, and sleeps well, though he is oftener in the hands of the Doctor than he ought to be, who, however, always manages to patch him up again by a little alterative medicine and a run at the sea-side."

Look at Tom's throat; there you will probably detect the source of all the mischief, in the presence of tonsils, more or less enlarged, filling up and obliterating the space between the arches of the palate, the sharp outlines of which are scarcely, if at all, discernible.

Then among the girls of the family, the watchful mother cannot understand why Tiny (she is called Tiny because there is less development of body and limb than in her sisters) is always so mopish and quiet, so little disposed to join in the frolic and fun going on around her, so demure, so free from the spirit of coquetry natural to young girls!

Let the throat be examined, and though there may be no great enlargement of the tonsils, there will be enough to cause ill-health in the manner presently to be pointed out. If there were any great enlargement, the voice would be affected, the patient would breathe through the mouth instead of through the nose, and there would always appear to be present a persistent cold, the breathing would be heard across the room, and there would be disturbed sleep through the inability of the patient to sleep with the mouth shut.

Now the mode in which delicacy of health is brought about by the presence of enlarged tonsils may be thus explained. The diseased glands are situated in what may be called the grand highway of life—the throat—over which every breath of air necessarily becomes contaminated as it passes into the lungs, whilst every morsel of food is rendered unwholesome by being imbued with the unhealthy secretion poured out upon it from the diseased glands on its way to the stomach; hence the patient may be said to be always breathing an impure atmosphere, and eating tainted food. The effect upon the health is precisely similar to that which such conditions of existence—bad food and bad air—pro-

duce in young persons in whom there is no enlargement of the tonsils—that is, they become pale and emaciated, weak and flabby, and of stunted growth. But there is yet another reason for the delicacy of health attendant on these cases. The enlarged glands, more especially when held back by adhesion, exercise a certain degree of pressure on the carotid artery as it proceeds along the side of the neck to supply the brain with blood. Any interruption of this kind diminishes the nervous energy of the system generally, and makes its mark upon the general health. Remove the morbid growths, free the arches of the palate, and in a few weeks you will scarcely know your patient to be the same person. I have proved it in hundreds and hundreds of cases. No medicine is necessary. On another occasion I will explain how best to manipulate; here it will suffice to say that it should not be done with the clumsy, unmanageable guillotine, which often includes within its grasp parts which should not be cut; but with a knife and forceps specially constructed for the purpose, no such mangling need be perpetrated. Shortly I hope to say something more about the arrest of development, and the delicacy of young persons as the consequences of enlarged tonsils, and with what certainty vigorous health may be restored by their removal.

CASE OF APHONIA OF NINE YEARS' DURATION.

Mrs. ——, of middle age, the wife of a Medical man, in the autumn of last year, called to consult me for an affection of the throat, involving among its consequences, complete Aphonia. For nine years she had never heard the sound of her voice, and she lost it after protracted watching at the death-bed of her child. On an inspection of the larynx I could discover no lesion whatever, but the vocal cords could not be brought into apposition, hence the loss of voice. Although no abnormal condition was apparent, it might have been supposed that such existed, from the fact, that for a long time previously she had experienced a most unpleasant taste from what appeared to her to be a fetid discharge occasionally rising into her mouth, from the left side of her throat. The local treatment consisted of a free sponging of the larynx with a solution of the nitrate of silver, thirty grains to the ounce; by means of a silver spatula, armed with a roll of cotton-wool well saturated with the solution and bent to the proper angle, the general health being at the same time attended to. This treatment was persisted in daily for a fortnight, when she suddenly recovered her voice. After leaving me (I think on the thirteenth day), she spoke to her friend in a "croaking" voice, and after the next application it became of the natural *timbre*. In a few days she returned to her home, quite well, and I had the satisfaction of receiving from her husband a letter of thanks for the cure which had been effected. For six weeks she retained the voice, and I was beginning to calculate on a permanent cure when she returned to me as bad as ever. I may mention that the fetid discharge never recurred after the first recovery of her voice, and I had been disposed to attribute my success to the brushing away of some excrescence or tumour, or deposit, from the neighbourhood of the left vocal cord. With my mind bent upon that idea, I had less faith than before, or perhaps than I ought to have had, in resuming the local treatment, still I persevered for a few days, until in consultation with Dr. George Johnson on the state of her general health in connection with the local malady, we agreed that for a time, at least, this alone should be attended to, and with this view she a second time returned to her home. Our joint laryngoscopic examination showed the wide open triangular glottis motionless when she attempted to speak, as I had myself frequently verified. But the lady herself having the fullest confidence in the success of the local treatment by caustic solution, resolved to make another trial. Not liking to trouble me again, thinking she had tried my patience long enough, as she was pleased to express it, she called upon another physician, who discovered that the vocal cords ran parallel to each other and never approximated in any one part! how this could be I know not; he professed to be confident of success, first by something he called the bromide of ammonium, then by cayenne pepper, then by nux vomica, then by strychnine all conveyed upon the larynx by vapour saturated with these substances, and lastly, by electro-galvanism, on the plan, of Dr. Morel-Mackenzie, but all failed until at her own suggestion was again tried, the solution of the nitrate of silver in vapour. In three or four applications the remedy had succeeded, and she again returned to her home. I have been surprised to hear that in three weeks this case was reported at the Pathological Society as a permanent cure, after, as it was said, Dr. Johnson and myself had failed! For my patient's sake I trust it may be so, but my experience in similar cases teaches me that this lady will again experience a temporary loss of voice, indeed, she has already had signs of it leaving her, though of her ultimate recovery there can be little doubt.

My intention in quoting the foregoing case is not to bring it forward as possessed of any novelty, but to show that we have gained nothing by any of the new-fangled remedies, or the new-fangled modes of applying them. If nitrate of silver applied to the larynx by saturated vapour will cure, so will nitrate of silver by saturated water. And a probang of sponge, or a silver spatula, devised for the purpose, armed with a roll of cotton-wool and bent to a proper angle so as to command the glottis, will be as efficient an instrument as the vaporiser. I have nothing to say against the electro-galvanic appliances of Dr. Morel-Mackenzie, of which, in many cases I think highly.

Lastly, let me entreat the readers of Medical journals to receive with caution the statements, made at the Medical Societies, which by a suppression or by exaggeration of facts, are not always trustworthy or truthful.

[*From the Case-Book of* ARTHUR LEARED, Esq., M.D.]

MANGANESE AS A REMEDY IN DISEASES OF THE STOMACH.

Pain caused by food is a very common functional affection of the stomach, and it affects women more frequently than men. Its ordinary position is at a spot just below the ensiform cartilage, but it may be localised at other points over the region of the stomach. At times it is diffused over a considerable space. When it has continued some time and especially if its seat is the spot first mentioned, the affected part feels sore on pressure, and this soreness may remain after cessation of pain. In many cases pain extends a good way upwards beneath the sternum, more rarely it is diffused downwards towards the umbilicus, or even below it. It frequently extends towards the right in the track of the duodenum, and is sometimes experienced in the cardiac region itself. In many cases pain shoots from the part locally affected as from a focus, in various directions through the thorax, frequently to the upper part of the back.

The perception of pain by different individuals is very variable, which partly accounts for the varying descriptions of the present affection. By some patients it is described as a dull continuous pain, by others as of a tearing, gnawing, or scraping nature, or like that which might be caused by a tight ligature.

The pain usually comes on from a quarter of an hour to an hour after a meal, but in severe cases is induced by taking even a few morsels of food. Its duration is uncertain but it usually last some hours. There appears to be always a short interval between the time of swallowing the food and the occurrence of pain. A valuable means of diagnosis between it and the pain of ulcer of the stomach in which pain generally happens immediately on swallowing solid food, is thus afforded. But the intensity of pain afford no measure of the gravity of the disease. The pain of cancer or of other organic diseases of the stomach may be less severe than that which is purely of a functional nature. Flatulence with a sense of distension are experienced

some cases, while in others they are entirely absent. Constipation is not a prominent feature of the disease.

The pain and tenderness are seldom connected with gastritis, as their transient nature, as well as the accompanying symptoms, sufficiently prove. They are simply an expression of exalted sensibility of the mucous membrane of the stomach, which becomes intolerant of the natural contact with the food, or, else of the gastric juice itself. The facts that the pain does not come on until the food has been some time in the stomach, and that albuminous food—that which requires gastric juice for its reduction, causes suffering, while starchy aliments cause it in a less degree, or, not at all—support the idea that the gastric juice is its source. I have been led by several circumstances to the belief, that the epithelial coating of the gastric mucous membrane is imperfect; that it is either shed too rapidly, or, owing to its imperfect growth, is inadequate for the protection of the delicate surface which it covers. Thus, the state of the tongue whose surface is continuous with that of the stomach, is generally very characteristic of the disease. Owing to a denudation of its epithelial covering, its extremity is very red, and its irritable-looking papillæ stand prominently out. The effect of treatment also proves that inflammation is not concerned in the disease.

I have thought it necessary to describe in some detail the nature of the disease before bringing forward a new remedy for it, because there are other painful conditions of the stomach which are not benefited by the same means. Its successful use will, therefore, greatly depend on accuracy of *diagnosis*. The gastric pain caused by gout, generally *connected* with an excess of acid is not removed by the same treatment; the pain which attends organic disease of the stomach is little influenced by it, and the same may be said of the neuralgic pain, which is especially apt to occur when the stomach is empty.

In the treatment of the disorder before us, direct sedatives seldom give more than temporary relief. Opium has the great disadvantage of inducing constipation. Prussic acid, with or without alkalies, so useful in some kinds of stomach pain, is generally futile. But the nitrate of bismuth has long been in deserved repute; more recently it has been almost superseded by its carbonate. These preparations are also open to the objection that they induce constipation. Both these substances are but sparingly soluble in the fluids of the stomach, and it occurred to me that their beneficial action may be exerted in a mechanical manner. It seemed possible that the diffusion of an inert powder over the walls of the empty stomach might, as it were, blunt the over sensitiveness of its mucous membrane. With this view I tried, in several cases, the effects of silex prepared by precipitation from its solution, a perfectly inert and insoluble powder. The results were not encouraging. Passing then to substances which combine mechanical with a special action, I tried in many cases the saccharated carbonate of iron with little success. A fair trial of the magnetic oxide of iron yielded no better results. All the substances mentioned were given in doses of from x. to xx. grains. In pursuance of the same inquiries the black oxide of manganese, freed from impurities, at length came under trial. Here the results have been unexpectedly satisfactory. After having used it in several hundred cases, both in hospital and private practice, and after an experience of some years, I do not hesitate to pronounce it a most valuable addition to our stomach remedies. It is certainly more efficacious in allaying the hyperæsthetic state of the mucous membrane than bismuth. This has been proved by alternately exhibiting each remedy for a week at a time in severe cases, and carefully noting the results. But, independently of this, manganese has one cardinal advantage—it does not constipate. Assuming them equal in other respects, this alone is enough to stamp its superiority over bismuth, in the use of which we are constantly obliged to teaze the gastro intestinal surface with irritating purgatives. Another advantage not to be overlooked, especially in hospital practice, is this—the purified oxide of manganese can be procured at about one-sixth the price of the preparations of bismuth. I possess notes of a great number of cases treated by manganese which incontestibly prove its efficacy. Space will not at present allow of these details, but the result of its trial in forty hospital out-patients, men and women, briefly stated, must suffice. The duration of the disease ranged from three weeks (the shortest) to several months and even years. The dose of the manganese was, in almost every instance, ten grains taken three times a day before meals. Alterations in diet could have had little influence in these cases.

After having taken manganese one week,

Pain was quite removed	in 12	
Very much relieved	in 15	28
Relieved	in 10

Patients did not attend	8	
	28	

Some of these patients continued taking the medicine for several weeks, and although a few who ceased to attend may possibly have remained unrelieved, no instance of failure came to my knowledge.

I was particular in ascertaining the effect on the bowels, and in four cases it is noted, that the medicine was thought by the patients to constipate, in three of these only slightly. More extended observations, however, convince me that it has no constipating effect. In one case, on the other hand, it was stated to have purged.

Manganese is also highly useful in pyrosis, generally removing, first the watery discharge, and afterwards the pain in a short time. In certain irritable states of the stomach it is also of much service. In one remarkable case, in which a woman had been affected with vomiting for many months, after the failure of bismuth, manganese was very successful in quieting the stomach.

The purified oxide of manganese may be given in doses of from five grains to half a drachm, according to the severity of the case. I tried the carbonate of manganese in a few cases with good results as regards pain, but in doses of ten grains it is apt to induce nausea, or even vomiting. The sulphate given in solution also allays pain, but I found that even five grains is still more liable to disagree with the stomach.

The ordinary black oxide of manganese is very impure, and therefore unfit for use. The purified manganese may be obtained from Messrs. Garden and Robbins, 372 Oxford street, W. I shall feel indebted to any gentleman who may make a trial of the remedy, for a report of the results.

12 Old Burlington street.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By ROBERT HUNTER SEMPLE, M.D.,

Senior Physician to the St. Pancras and Northern Dispensary.

The present century has been fertile in results advantageous to the advancement of Medical science and practice. The happy discovery made by Laennec that certain solid bodies conveyed to the ear the sounds generated in the thoracic region of a patient, opened up the whole domain of chest-diseases to the cognisance of the physician, who before only made a dubious guess at morbid processes which he now detects almost with certainty. Strangely enough the stethoscope revealed the existence of many sounds which are heard just as well by the unassisted ear, but which had not previously been heard or described, because they had never before been sought for. The adaptation of

condensed rolls of paper (which formed Laennec's first stethoscope) and of wooden cylinders, to the auscultation of the chest, merely proved that certain sounds were generated within that cavity, and they might have been heard there by Hippocrates himself, if he had placed his ear in the right place. The invention of the stethoscope was, in fact, the discovery made for the first time that the best way to ascertain the healthy and morbid condition of the heart and lungs was to listen to the sounds which these organs emitted: and whether the physician listened to the chest itself, or to the sounds transmitted from the chest through the stethoscope, was a matter of comparatively little importance, so that he really heard them, and duly estimated their value.

The advancement made in pathology kept pace with and threw abundant light upon the researches made by Laennec; for by continual comparison of the sounds heard during life with the appearances observed on necroscopical examination, the true meaning of the different sounds was gradually unfolded, until the practitioner was enabled to detect the state of matters going on within the chest with almost as much certainty as if the parietes were made of transparent materials, and he was able to see through them into the interior.

The brilliant discoveries of chemistry lent a valuable assistance to every branch of pathology, investigating with the utmost minuteness and accuracy the composition of the solids and fluids of the body, and the changes which they undergo under the ceaseless operations of life. The improvements in the microscope, its greater cheapness, and the increased facilities thereby afforded for the general employment of this instrument, have progressively developed the construction of the minute tissues of the human organism, the processes by which they spring from their original germs, and the degeneration which they undergo from the influence of disease.

The study of the Diseases of the Heart may be said to have begun only after the publication of the Treatise of Laennec, who, although including Cardiac Diseases in his volumes, and describing some of the morbid sounds of the Heart, threw no great light upon the subject, which was taken up and pursued with much greater success by Bouillaud and Andral in France, and by Hope, Williams, Latham, and Richard Quain in this country.

The human body consists of a number of parts so intimately connected and interwoven with one another that it is exceedingly difficult, in innumerable instances, to determine the exact sequence of morbid action; whether a given organ is the original seat of disease, or whether it is only secondarily affected, whether the local mischief originates the constitutional malady, or the constitutional malady predisposes to or excites the local mischief. This remark is especially applicable to the affections of the Heart, an organ which sympathizes with every other organ and structure of the body, and which supplies to every part its indispensable nourishment. The pulse, that *fallacissima res*, as Celsus terms it, gives timely intimation of the existing condition of the central organ of the circulation, and tells us whether it is beating in its regular course or is accelerated in its movements, whether its beatings are performed with increased or diminished energy, whether the powers of life are exercised too vehemently, or whether they are flagging in their course.

Still in these days of the subdivision of mental labour, and of the immense accumulation of materials too mighty to be comprehended by a single mind, the mere necessity of the case, rather than any natural boundary, induces men to choose one subject in preference to another for their special pursuit and cultivation, and viewed in this light the study of the Diseases of the Heart presents many attractions. The very facts that this organ is the centre of the circulatory system, that the arrest or suspension of its action causes actual or temporary death, and that its derangements must entail serious consequences upon the rest of the system, invest with peculiar interest every condition which it presents, and render the investigation of its healthy or morbid actions a matter of paramount importance in the practice of Medicine. The wonder indeed is that an organ so important may be seriously impaired (as is often the case) without causing a correspondingly dangerous state of the general system, and that life and comparative health and comfort are quite compatible with even advanced disease of its structure. Nay, more, it is often the case that palpitation and severe pain of the heart may cause the utmost distress to the patient, when there is no morbid lesion at all; and *vice versâ* the most insidious and destructive changes may be going on in the texture of the organ while the patient is wholly unaware of their existence. Considerations such as these, while they ought to make us the more careful to investigate every morbid condition, should render us equally guarded in forming a prognosis as to the result of a given case, which may entirely falsify our anticipations, if we were guided solely by physiological or pathological reasonings.

The diseases of the heart may be *acute*, as in inflammation of the organ, or rather of the membranes which cover or line it; but this inflammation is rarely idiopathic, being usually associated with some diathetic condition of the system. The *chronic* diseases are far more numerous, and they also are rarely idiopathic, being usually the results of the acute inflammations, or being produced by disease of organs associated with the heart in function, or by constitutional disturbances. The diseases may also be divided into *Functional*, or those which are unconnected with any perceptible lesion, and *Organic*, or those in which there is visible or tangible change in structure. The latter are, of course, the more interesting to the morbid anatomist, although the former are equally important to the pathologist, who does not always look for visible change of structure to account for every deviation from the healthy standard.

The organic changes consist in inflammation of the membranes, of enlargement of the heart itself, of obstructions or insufficiency of its valves, of diminution or weakening of its muscular fibres, and of deposition of fatty matter within the substance of the latter. This fatty degeneration of the heart, although it has been admirably described and demonstrated of late years, and although it has satisfactorily explained a great amount of the mortality from heart disease, still demands further and most careful consideration, more especially in connection with the physical signs which indicate its existence during life, and with the remedial measures, the adoption of which might arrest its progress.

Another most important subject developed in very recent times in connection with cardiac pathology, is the value to be placed upon the existence of fibrinous concretions, or what were formerly called polypi, in the large vessels of the heart. These bodies, as is well known, were described as morbid products by the bygone race of Medical practitioners, but from the great frequency of their occurrence in post-mortem examinations, they were generally regarded by most practical anatomists as merely changes occurring from ordinary causes some little time before death. In fact, I had so often found them myself that I ceased to regard their appearance as of any importance, and when some years ago, my friend, Dr. Richardson, started the theory that their formation was the *cause* rather than the accompaniment of death, I was inclined altogether to doubt the truth of the opinion. Since that time, however, Dr. Richardson has worked out his views with so much energy, as to support, in a certain sense, the view that these fibrinous concretions may, in particular cases, be formed suddenly, and may cause rapid dissolution. This subject has received a further development by the curious discovery that portions of fibrinous concretions may be carried from the pulmonary artery into the capillary vessels of the lungs, or from the aorta into the arterial ramifications throughout the system, thus causing local obstructions which may terminate according to the structure affected, in gangrene, in inflammation, in congestion, or in softening. The local obstructions have received the general name of *thrombosis*, and the transportation of minute fragments of clots to distant parts is designated under the name of *embolism*.

(To be continued.)

MEDICAL SOCIETIES.

HARVEIAN SOCIETY, DEC. 17th, 1863.

PRESIDENT, DR. H. FULLER, in the chair.

A paper was read by Dr. TILBURY FOX,

ON PORRIGO.

The author first commenced by objecting *in toto* to the further use of the term *porrigo* in dermatology. The term tinea would be a proper substitute in the parasitic class of cases; and the impetigo contagiosa, in the form of scalp disease, more recently known as porrigo startinii. A description was then given of the disease as it affects the different parts of the body; on the scalp as isolated circular, flat, yellowish, granular looking scabs, without any inflammatory areola, developed as a primary disease from a small pustule; on the general surface as small red points, isolated, most usually becoming pustular, then quasi bullous (always umbilicated) and presenting a circular form with more or less redness around, attaining the size of a shilling, or more, and then breaking out into superficial, wet leather looking ulcerated surfaces. The contents of the pustules were shown to be made up of puriform material, (a plastic lymph) pus, fat, epithelial cells, and parasitic animal and vegetable growths, resembling the trichophyton, and also bodies resembling amyloid corpuscles. The parasites were only found, as an accidental component of the disease. *Dr. Fox* noticed certain deviations from the normal standard. The disease is essentially and highly contagious, and the specific contagious quality resides in the secretion of the pustule, and is not parasitic, as shown by microscopic examination. Cases were quoted to show that the disease was inoculable by the introduction into the skin of a sound person of some pus, or of some of the discharge. Dr. Fox then proceeded to point out the similarity between cases of impetigo contagiosa and so called "bastard vaccinia." That "bastard vaccinia" was, in many cases, simply impetigo contagiosa, and this mostly followed vaccination, or could be traced by contagion through a series of cases to some one subject in whom the disease had followed so close upon vaccination, that the I. contagiosa of the scalp often co-existed with so-called bastard vaccinia of the surface. That inoculation produced a pustular condition, closely resembling vaccinia, and Dr. Fox touched upon the explanation of the relation of this disease to vaccination, and asked what, if any, is the modifying influence of the universal practice of vaccination upon existing disease. Some of the cases appeared to be impetigo modified by vaccination. Dr. Ross's observations were referred to. The author had described the disease as it had lately been seen in the quasi epidemic form among the patients in his department of "Diseases of Women and Children," at the Farringdon Dispensary.

The PRESIDENT observed that a large field of observation was opened out by the connection between vaccination and scrofula. Vaccine might cause eruption, either by constitutional irritation or by specific poison. At Southampton, children who were vaccinated had had a remarkable epidemic of skin disease.

Dr. HILLIER thought that the author of the paper had included several diseases under one head. He was fully satisfied that impetigo was sometimes contagious, and that some of these cases seemed to have all the anatomical characters of ordinary non-contagious impetigo, whilst others had the characters so well described by Dr. Fox. This differs from ordinary impetigo in the character of the secretion and in the extension of ulceration beneath the raised cuticle. The existence of umbilication was generally due to the cuticle dipping down into a sweat duct, and might be present or not. He was not quite sure whether this was a separate disease, or whether rupia, &c., might not also in children occasionally become contagious. Scabies and pediculi complicated the question. The term porrigo is a bad one, having been applied indiscriminately to all kinds of scalp diseases. Dr. Hillier stated that Willan and Bateman's porrigo favosa was not fever, but the contagious impetigo; whilst *P. lupinosa* answered to favus, and *P. scutulata* to *tinea tonsurans*. He had several times heard from practitioners that their supply of vaccine lymph appeared to have become impure, and vaccination by it had caused eruptions. Was this caused by lymph having been taken too late, or by its having come from unhealthy subjects? Splitting of hairs is not always due to parasitical growths, as Dr. H. had found by experience, and as *à priori* considerations would prove.

Dr. CHOWNE thought the author's views dangerous, as casting discredit upon the important practice of vaccination, without being grounded upon sufficient observation of facts. He believed eruptions of this kind occurred merely coincidently, not in consequence of vaccination.

In reply to Dr. Drysdale, the author showed that he used sulphur ointment as an external application, and cod-liver oil and iodide of potassium internally.

Dr. TILBURY FOX observed, in reply to Dr. Hillier, that he had been very careful in drawing logical conclusions in the matter. He had noticed that this disease frequently followed in the wake of vaccination. He could not agree with Dr. Hillier that there was any proof of the contagious nature of ecthyma or rupia in any case. As to pediculi and vegetable parasites being a cause of contagion, there was direct proof to the contrary. They were altogether absent in the majority of cases. The splitting-up of hairs into their ultimate fibres was thought by Dr. Hillier not to be due always to parasitic disease, but a condition of fungus capable of producing the lesion was generally overlooked, and as to umbilication it was due to the pathological behaviour of the diseased derma.

PLYMOUTH PUBLIC DISPENSARY.—TESTIMONIAL TO DR. COOKWORTHY.—At a special meeting of the committee of the above dispensary, after appointing Dr. Cookworthy Consulting Physician, in accordance with the request of the Court of Governors, it was resolved—"That a marble tablet be erected in the committee-room, at the expense of the institution, commemorating the invaluable services of Dr. Cookworthy to the charity, during a period of fifty years. That a public subscription be entered into for promoting the acquisition of a handsome testimonial to be presented to Dr. Cookworthy, the subscription to be limited to one guinea. That the nature of the inscription, and of the testimonial, and the promoting of the subscription, be left to a special committee, which was appointed for the purpose."

A TURKISH "DIVINE" PRACTITIONER.—The following advertisement appears in our Stamboul contemporary, the 'Terjuman Ahval'—"Headaches, tooth aches, lumbago, eye-sores, fever, &c., cured by a celebrated divine just arrived from Asia Minor, by breathing on the patient and by charms. Address: Dede-kave, at Allserai."

A WORTHY EXAMPLE. — A CHRISTMAS OFFERING. — The workmen of the factory of Messrs. Collards, pianoforte manufacturers, of Camden-town, have contributed by small subscriptions the sum of 8*l.* 10s. 2d., and presented the same to the governors of the University College Hospital, as a simple offering of their appreciation of the goodness and worth of the institution, and the promptitude and benefits afforded to those in sickness and distress.

THE CITY LUNATIC ASYLUM.—A meeting of the officers of the City of London Union has been held for the purpose of considering the steps to be adopted to prevent the transfer of the new City Lunatic Asylum to the county justices. Resolutions condemnatory to the transfer were unanimously adopted.

TESTIMONIALS.—The patients of Joseph Holmes Buxton, Esq., M.R.C.S., of Islington, invited him to a sumptuous luncheon on the 19th ult., at Middleton Hall. About eighty gentlemen were present. The chairman, the Rev. T. Woolmer, in a most suitable speech, presented a testimonial, consisting of a brougham, horse and harness, together with a silver salver, in recognition of the valuable professional services which for many years he has rendered to the neighbourhood.

TO OUR SUBSCRIBERS.

Since 1861 *the Subscription to this Journal has been* 19*s.* 6*d. per annum, if paid in advance, and* 21*s.* 8*d. credit.*

In consequence of the many improvements introduced into the New Series, with others in contemplation, involving considerable outlay, placing the Journal quite on a par with its contemporaries, the subscription henceforth will be 21*s.* 8*d. if paid in advance, or* 26*s. credit.* 6*d. per Number stamped,* 5*d. unstamped. Or the Journal can be procured through any Bookseller or Newsman in the usual course of trade.*

*** *Owing to the demand made on our space for the insertion of Advertisements, we have been compelled to postpone the publication of several important communications.*

THE MEDICAL CIRCULAR.

ADDRESS
to
THE MEDICAL PROFESSION.

IT is now twelve years since the first number of the MEDICAL CIRCULAR was offered to the Profession, and during the period that has elapsed between that time and the present, a continued course of success has justified the boldness with which we undertook the publication. Those who are acquainted with the difficulties of literary enterprises will easily imagine the obstacles we have had to surmount in the progress of our career, and we need not hesitate to remark that we have occasionally fallen, while steering our course, upon rocks and sand-banks, which it will be our duty henceforth to detect and to avoid.

Starting at first only as a review or summary of the Medical knowledge published by our contemporaries, the MEDICAL CIRCULAR has gradually extended its scope, and has aimed at, and attained, an amount of originality and variety which now place it in the first rank of Medical periodical literature.

It is time to review the position which we occupy, and while guided by somewhat different auspices from those under which we have hitherto courted public favour, it becomes our duty to develope the plans which we have sketched out for the future management of the Journal. While avoiding the paths which experience has proved to be erroneous, we do not pretend that the new ones into which we enter may always be the right ones; all we can claim is indulgence for our good intentions, and credit for the honesty of our motives. The zeal and energy of our predecessors we hope to imitate and preserve, while we abandon some former features of our Journal, or strike out new ones, or modify any or all of them, as circumstances may require.

One peculiarity which at first distinguished our pages, namely, that of offering a reflex of all the Medical knowledge of the day throughout the world, will be studiously maintained. The interchange of thought among the nations of the earth, effected by means of those typographical appliances which modern science has devised, and facilitated by the increased rapidity of transmission in latter days, is peculiarly valuable to the Medical practitioner in making him acquainted with the most recent discoveries and inventions in medicine and surgery throughout the habitable globe. Our Summaries, condensed from this extensive field, will present without fear, favour, or exclusiveness, abstracts of every paper written on Medical subjects; and these abstracts will be alike acceptable to the busy practitioner, who wishes to acquire a knowledge of existing Medical and Surgical art and science, but who has not time to wade through the mass of language in which it is enveloped, and to the man of study and reflection who desires to know the titles and the subjects of all new contributions to the literature of our common calling. Very few of those who read our abstracts are probably aware of the labour involved in their compilation: but those who are accustomed to literary toil need not be informed of the fact and the time required to winnow the corn from the chaff, and to seize the salient points of an article from amidst the verbiage with which it is too often encumbered. We can fearlessly assert that the pages of the MEDICAL CIRCULAR offer a complete library of reference to all papers on practical medicine presenting the slightest claim to originality, published in the English language, and to many written in foreign tongues. This feature of the CIRCULAR, under the heading "Spirit of the Periodicals," which distinguishes us from our contemporaries, raising us beyond the level of an ephemeral print, and entitling us to a permanent place on the library bookshelves as a work for future reference, will be carefully continued.

For some time past, we have incorporated with this Journal the rich stores of information contained in the French 'Journal of Practical Medicine and Surgery,' and have thus presented a digest of continental as well as of British Medical literature. This feature will also be retained, although the plan will be somewhat modified; and, instead of printing *in extenso* the translation of the whole Journal, we shall hereafter select only such parts of it as are of peculiar interest or importance, allowing it to appear as the foreign portion of the "Spirit of the Periodicals." The space thus left at liberty will further enable us to introduce somewhat of a novel feature, which is well illustrated in this the first number of the New Series, namely, comments and cases from the case books of practical men—we say advisedly practical men—men who cannot find time to sit down to prepare a course of six or twelve lectures for this or that journal, but who would not regard it as a tax upon their time to transcribe from their daily records of cases, some one which will seem to elucidate a successful mode of practice, or conform or refute a supposed

Medical fact. The consulting and the general practitioner are equally invited to enrich this deparment of the Journal with such contributions of cases occurring under their own observation and treatment.

Our Hospital Reports, temporarily suspended in consequence of our space being otherwise occupied, will be resumed, and a picture will thus be presented of the progress of practical Medicine and Surgery throughout the British dominions; but as we do not profess that our own personal sphere of observation can extend beyond the limits of the Metropolitan Hospitals and Dispensaries, we shall feel obliged by the transmission from provincial or foreign institutions, of short clinical Reports to which we shall be happy to give insertion as opportunity offers itself.

With respect to the Editorial department, we really think it necessary only to remark that it will be conducted with the same spirit of fairness and energy by which it has always been characterised. Being ourselves among the working members of the Profession, it is no part of our plan to sit still with a pen behind our ears in a comfortable office, and while ourselves free from the cares and anxieties of Medical life, to criticise or it may be, condemn the proceedings of our brethren. No, we place ourselves in the same position as they occupy, and while withholding our countenance and support from any instances (if there be such) of bad faith or unfair dealing in our ranks, we shall readily sympathise in those numerous trials and annoyances to which our fellow-labourers are exposed in their daily ministrations, and shall, with all the power we possess, defend the honourable practitioner of Medicine from his assailants, whether among the public in general or among the prejudiced portion of the public Press. Never was there a time when our Profession needed this moral support more than at the present, when it is the fashion to attribute base motives to many of our most honourable and self-sacrificing brethren, and when, we regret to add, even some of our Medical contemporaries do not exhibit more than a lukewarm advocacy of gentlemen so unjustly attacked. For ourselves then we may adopt, although in a limited sense, the phrase applied by the philanthropist in Terence's play to all mankind,

"Homo sum, nil humani a me alienum puto,"

which we may paraphrase by the observation that we are working practitioners of Medicine ourselves, and that the cares and anxieties of our Medical brethren, their trials and vicissitudes, their joys and their sorrows, we feel as we do our own.

These remarks are, of course, partially applicable, and with a sad significance, to those unfortunately numerous cases of persecution carried on against Medical men, which it has been our painful duty of late to record and to comment upon, and which, if allowed to proceed in the same reckless manner as heretofore, will render the practice of Medicine and Surgery an utterly dangerous pursuit. The results of human sickness and infirmity are in the hands of God alone, and man is but the minister and the interpreter of Nature; the quality of the disease, and its successful or unsuccessful termination, must often be obscure, and ἡ κρισις χαλεπη, *judgment is difficult*, is an aphorism as old as Hippocrates. If, then, the Medical practitioner is to be dragged into a court of law for results which no human wisdom can anticipate or prevent, nay more, if he is to be answerable when his treatment has been perfectly successful, but where from corrupt or revengeful motives, his patients think proper to turn round against him, we repeat, that under such circumstances, the Profession of Medicine will become so dangerous that none will dare to follow it except those who have no reputation and no money to lose, and who would consequently be exempt from persecution.

The injustice inflicted upon Medical men, in certain departments of the public service, has been freely exposed in our columns, which will still be open for the redress of grievances in this direction. But truth compels us to add, hat very great improvement has already taken place in this respect by the efforts of the Medical Press, backed by the voice of the Profession; and still greater triumphs may yet be achieved by patience, unanimity, and perseverance. In the administration of the Poor Laws, an immense boon has lately been granted to Medical men, by making their offices permanent, except in cases of legal disability, or of proved misconduct; and thus the power of capricious dismissal of Medical Officers by Boards of Guardians is altogether annihilated. The inequality of payment in different districts, and the enormous amount of work imposed upon some Medical Officers, are just subjects of remark, and the exposure of this kind of hardship by the Medical periodicals, is often followed by redress.

We shall devote even more attention than heretofore to our Review of Books, a department requiring not only great learning, but also tact and discrimination, and the gentlemen to whom this task has lately been confided, and by whom it will henceforth be performed, are in all respects admirably qualified to execute their duties in a spirit of fairness, justice, and impartiality. No undue reticence will ever prevent us from expressing a righteous opinion upon the merits of the publications which may be presented to our notice, and on the other hand, no mean spirit of jealousy or rivalry will ever intervene to warp our judgment or induce us to deny merit where merit is due.

In conclusion, we have only to ask the indulgence of our readers for any shortcomings of which we may be hereafter culpable. Being no novices in the art of journalism, we know and feel that the path we tread is difficult, and one in which thorns are more abundant than roses. The jealousy unhappily existing among some members of our Profession, the class-interests which unfortunately linger among our ranks, the over-zeal of some of our number, the apathy of others, the want of *esprit de corps* to bind us all together in one common brotherhood, all these circumstances render the duties of a Medical editor sometimes an embarrassing, often an arduous, generally a thankless task. All we can say for ourselves is that we have no class-interests to defend, no personal ends to gain, no unfriendly feelings to gratify; we wish to do justice to all, and to promote, as far as lies in

our power, that unanimity of which our Profession stands so much in need, and we have no enemies except the enemies of our common calling. With regard to our contemporaries we shall, while freely commenting upon the opinions they may express, abstain most carefully from the use of any but gentlemanly weapons.

With these remarks we enter upon the duties of our new volume, wishing all our readers a "Happy New Year."

SUMMARY OF THE WEEK.

THE DEATH OF MR. THACKERAY.

The decease of Mr. Thackeray in the prime of life has cast a melancholy shade over the festivities of our late Christmas, and has, in the language of Dr. Johnson as applied to the death of Garrick, "diminished the public stock of harmless pleasure." Mr. Thackeray was a strongly built man, but of pale rather than florid complexion. He was usually healthy, except in the year 1849, when, as is well known, he suffered from a severe illness, for which he was treated by Dr. Elliotson, to whom, in the preface to one of the volumes of *Pendennis*, he offers a warm tribute of gratitude and respect. The only unfavourable symptom from which he occasionally suffered was vomiting, and he experienced an attack of this nature the day before his death, but no importance was attached to the circumstance owing to the frequency of its occurrence. He was also subject to an ailment of a surgical nature, for which he intended to avail himself of the services of a well-known and distinguished surgeon. On Thursday morning, December 24, he was found lifeless in bed, in his usual recumbent attitude. The *post-mortem* examination was made in the afternoon of the same day, and the cause of the death was found to be the effusion of a large quantity (from 6 to 7 ounces) of serum, between the dura mater and the brain. As soon as the membrane was punctured the effused fluid was poured out in a continuous stream. This effusion is probably to be attributed to the frequent attacks of vomiting, to which the great humourist and philosopher was subject in late years.

THE CRAWLEY COURT-MARTIAL.

Colonel Crawley has been honourably acquitted of the charges brought against him, as was generally expected from the manner in which the case was conducted, and the result has been received with great satisfaction by the military authorities, but very coolly by the public. A feeble attempt has been made to get up a subscription to pay his expenses, but it appears to have met with little response. For ourselves, as Medical journalists, the affair presents very little interest, except that the Colonel attempts to throw the blame of the death of Serjeant-Major Lilly (if any blame attached to anybody), upon the subordinate officers of the regiment, including the surgeons, Dr. Turnbull and Mr. Barnett. To our infinite surprise, we find the 'Lancet' joining in the censure which the Colonel endeavours to cast upon the Medical officers, and which, in our opinion, is entirely undeserved. These la ter gentlemen appear to have had a very difficult part play, and whichever way they turned, under the th existing state of the regiment, they would have gone wro As it was, they did nothing but their bare duty; th found a man, hitherto bearing an irreproachable charact placed in close arrest, and they are now blamed, if understand the matter correctly, for not demanding release. It is quite clear that if they had done so, th would have been reproved for stepping beyond their dut and interfering with the discipline of the regiment; and t very small indulgence which they did ask for and obta for the serjeant, were accorded in such an ungracious ma ner by the Colonel, as probably to dissuade them fro making any further representations or remonstrances. T principle of making the medical officers the scape-goats answer for any mismanagement or mishap in a regime is an old device, but we did not expect the 'Lance to applaud such a stale trick.

WHO IS TO BE THE NEW PRESIDENT OF THE MEDICAL COUNCIL.

The General Medical Council will hold a special meetin this day week, at the premises in Soho square for the pu post of electing a President in the room of the late M Green. We have already stated that the gentlema unanimously designated by the voice of the Profession fo the vacant appointment, is the respected President of th College of Physicians, Dr. Watson, who, from his persona position and character, and his total independence of cliqu or party, is considered to be the very best selection tha can posssbly be made. An absurd statement has appeare in the 'Lancet' to the effect that a considerable party in th Medical Council is desirous of promoting the election o Dr. Burrows to the Presidential Chair, but we have ampl means of knowing that no such party exists, and tha Dr. Burrows is himself promoting the election of D Watson. The only fear entertained is that the latter ge tleman will decline to undertake the labours and respo sibilities of the post, but we hope that he will reconsid the objections which we believe that he has urged, an will thus gratify the members of the Council who, i common with the Profession are unanimous in desirin his acceptance of the honour thus intended for him.

THE RESPITE OF GEORGE VICTOR TOWNLEY.

It should be generally understood that the convict Tow ley will be transferred from a prison to a lunatic asylu on the ground that he is now insane, and consequently longer a responsible agent. Whether it be the fact that th hereditary tendency to insanity has now become develope or whether his long imprisonment and his remorse f the crime he has committed, have finally unsettled h reason, it is impossible to determine, but it is beyond a doubt that he is now insane. In justice to Dr. Forb Winslow, it ought to be stated, that that gentleman test fied as to the state of Townley's mind only at the tim when he saw him, and when, as it now turns out, he w actually hereft of his reason. We have cause to rejoice ther

fore that a lunatic has been spared from public execution, but, we should have been still more rejoiced if the person so respited had been a poor man instead of a gentleman, for we cannot help believing that if he had been a poor man he would inevitably have been hanged. He has been saved from the gallows, in fact, by Dr. Winslow. In the case of the poor unfortunate lunatics, Fooks, Burton, and Holden, who were hanged last year, we supplicated in vain that a commission of inquiry should be appointed to examine into the state of their minds, but the Government were as stern as Shylock in the Merchant of Venice—

"*Portia.* Have by some surgeon, Shylock, at your charge,
To stop his wounds, but he do bleed to death!
"*Shylock.* I cannot find it: 'tis not in the bond."

We merely asked for an inquiry in the case of the poor men, but the answer was that the law made no provision for the adoption of such a course, although it now appears that the existing laws are quite sufficient to meet such cases. Can it be said that the attention of the Home Secretary is merely bestowed on people in a good position of life, but is withheld from common soldiers, and half-idiotic and friendless boys?

THE MEDICAL STAFF OF ST. BATHOLOMEW'S HOSPITAL.

The senior physician to St. Bartholomew's, Dr. Burrows, has voluntarily resigned his post, although he is in the prime of life, and Mr. Skey has, according to recent by-laws of the hospital, become disqualified from holding any longer the position of surgeon, on account of his age. The case of Mr. Skey is rather a hard one, inasmuch as he occupied for a great number of years the ill-requited post of assistant-surgeon, and has only within a comparatively recent period received the honours and emoluments of the full surgeoncy. The present senior-surgeon of the hospital is very much older than Mr. Skey, but is exempted from the operation of the by-law because he was elected before it was passed. Nevertheless, it is felt that this gentleman is now so full of years and of honours that he might gracefully retire to make way for younger men, and such a step on his part would only add to the general respect which is entertained for his distinguished talents, and for the services which he has rendered to British surgery.

THE MEDICAL ACT AND THE CHEMISTS AND DRUGGISTS.

Some of the Chemists and Druggists are exceedingly alarmed a a proposition which has been laid before the Medical Council, to apply to Parliament for an amendment of the Medical Act, so as to bring the practice of Pharmacy in some way under the control of the law. The proposition in question originated, we believe, with the Irish members of the Council, the practice of pharmacy in the sister island being regulated by special local enactments: but we believe that the plan meets with little favour on this side of the channel. The chemists and druggists have, therefore, not much cause for alarm; still we cannot but think that their excessive repugnance to any legislative restrictions is rather amusing. We find that the Pharmaceutical Society, which has really done very great service in raising the condition of Pharmacy in this country, does not share in the sentiments entertained and expressed by the chemists and druggists who have lately met together to oppose the threatened amendment of the Medical Act. The Pharmaceutical Society, indeed, appears anxious that the business of the Chemists and Druggists should be placed upon a more satisfactory basis it is than at present, and it does not fear that any existing rights would be destroyed or injured, even if the legislature should demand from pharmaceutists some measure of education.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. SKEY commences the number with a paper entitled, "Records of Cases Treated in the Hospital" (St. Bartholomew's). He makes some remarks, in the first place, upon the diversity of treatment adopted at different hospitals for the same diseases and injuries, and he throws out a suggestion that the Medical Staff of each hospital should visit all similar institutions, and compare notes of the results of treatment every year for their mutual guidance. Mr. Skey then proceeds to give some practical hints as to the treatment of several common affections. In treating Varicose Veins, he condemns the use of needles, whether through the veins or under them, as their employment is rather dangerous, and as they generally fail to obliterate the veins. He prefers making a small number of small eschars on the most projecting surfaces of varicose veins, the escharotic being composed of pure potash and powdered lime. The Bursæ which come under the notice of the surgeon, are the bursa in front of the knee-joint, and the adventitious bursæ, called *ganglions*, on the back of the wrist and elsewhere. The former may become dilated by a collection of serum or pus, and the best treatment is to pass through it a moderately thick silk thread, which destroys the bursa; the treatment of the so-called *ganglions* is to evacuate the contents *entirely*, so that the opposite walls may be in absolute contact. Ranula is an affection, the exact cause of which is unknown, but Mr. Skey once extracted a portion of calcareous matter from what appeared to be the orifice of a duct. The best treatment is to pass a thread through the middle of the cavity. The treatment of Burns, according to Mr. Skey, should consist in the application of stimulants, as first recommended by Dr. Kentish, of Bristol, about half a century ago. The best stimulant is the nitrate of silver employed in solution in the proportion of from ten to fifteen grains to an ounce of water for an adult, and of less strength for a child. The best treatment of Chronic Ulcers is by the constitutional administration of opium, in doses of ten to fifteen drops of the tincture night and morning. After five or six days of such treatment, a large chronic and foul ulcer will throw out healthy granulations, and will eventually cicatrise. Dr. BRINTON communicates some "Clinical Remarks on a Case of Cerebral Meningitis." The patient was suffering from tuberculosis in the lungs and the intestines, and was seized with cerebral symptoms,

indicating effusion in the cranial cavity, and tubercular deposit in the brain. The examination made after death confirmed the accuracy of the diagnosis made during life Mr. W. S. SAVORY commences a series of "Observations on Caries, and it Relations to Necrosis." In the present paper he examines the process of ulceration as applied to Caries, and he shows that it consists not only in the removal of effete matter, but in the diminution or alteration of the substances forming the healthy structures. In caries, phosphate of lime is carried off, and the ulcerating bone exhibits evidence of the degeneration of the osseous tissue, and of the presence of oil-globules. DEPUTY-INSPECTOR-GENERAL T. LONGMORE, Professor of Military Surgery at the Netley Army Medical School, offers some "Remarks on the Recently Proposed American Plan of Treating Gunshot Wounds of the Chest, by 'Hermetically Sealing.'" We reprinted the paper advocating this plan, from the 'American Medical Times,' in the MEDICAL CIRCULAR of Oct. 28th, last year. Professor Longmore now examines carefully the nature of the proposed improvement in Military Surgery, and he comes to the conclusion that this kind of treatment can be usefully applied only in a very limited number of cases, and that in the great majority it will be attended with such serious inconveniences as to render its general adoption very unadvisable.

THE 'MEDICAL TIMES AND GAZETTE.'

Professor SIMPSON, of Edinburgh, commences a series of Clinical Lectures on the "Diseases of Women," with some remarks on Acupressure, or the artificial arrestment of the hæmorrhage from cut or wounded arteries by the pressure of a needle passed across their mouths or tubes. This subject, as Dr. Simpson remarks, belongs to the whole domain of Surgery, although the first idea of acupressure sprang from the study of a female surgical disease, namely, vesico-vaginal fistula. In the course of a very ingenious and learned argument, Dr. Simpson shows that the reason why most wounds inflicted in surgical operations do not heal by the first intention is because the ligatured arteries are wounded, ulceration and sloughing ensue, and the silk and other ligatures excite irritation which is inimical to the healing process. The practice of acupressure consists in passing needles, not *through*, but over or under the ends of the divided arteries, and thus compressing them against the living tissues and occluding their orifices. Dr. GEORGE HARLEY commences a course of Lectures on the "Urine and Diseases of the Urinary Organs." This first lecture is merely introductory, showing that urine is solid in some classes of animals, as in reptiles and birds, and in all animals devoid of a urinary bladder, but fluid in many others. Of liquid urines, that of carnivora contains uric acid, that of the herbivora contains hippuric acid. Dr. HANDFIELD JONES offers some records of a case of "Proptosis, Goitre, Palpitation, &c., with Remarks." The case was one of what is called exophthalmic goitre, and occurred in a female aged forty, appearing to arise from over-work and anxiety. The patient recovered under the use of nutritious diet, tonics, and sedatives. Dr. H. Jones thinks that the protrusion of the eye-ball in such cases is caused most probably by serous effusion in the orbit. Dr. PEACOCK commences the description of some cases of "Unusual Slowness of Pulse, with Remarks." He considers that this peculiarity is chiefly dependent on cardiac disease, and he refers to several cases in support of this view. Mr. J. G. HILDIGE, of Dublin, relates a case of "Sub-acute Glaucoma of both Eyes treated by Iridectomy." The patient was a lady aged thirty-five, in whom the symptoms of glaucoma were very manifest, and the sight was seriously impaired, but the performance of the operation was followed by complete recovery. Mr. Hildige takes the opportunity of defending the utility of iridectomy from its detractors, and he calls upon the latter to imitate the example of Mr. Wharton Jones, who once ridiculed the operation but now admits its value.

THE 'BRITISH MEDICAL JOURNAL.'

Dr. A. T. H. WATERS commences the number with the first of a course of Lectures on "Certain Mutual Relations of Physiology, Pathology, and the Practice of Medicine," delivered at the Liverpool Medical Institution. In the present lecture Dr. Waters points out some of the debateable topics in the physiology of certain important organs, as the liver, the glycogenic function of which has been asserted and denied, but which probably really exists; and he then refers to the present condition of our knowledge of cardiac diseases as a consequence of the advances made in physiological and pathological science. Mr. BERNARD BRODHURST continues his Lectures on "Orthopædic Surgery," his present subject being curvatures of the spine. He describes the causes of lateral curvature of the spine, or scoliosis, and illustrates his observations with some well-executed wood-cuts. Although the symptoms of lateral curvature are so obvious that it appears impossible to overlook them, yet instances occur where this distortion is not recognized, and Mr. Brodhurst mentions a case, in which, although the patient had a kind and attentive mother, the deformity was not even suspected.

REVIEW OF BOOKS.

The Principles and Methods of Medical Observation and Research: with copious Nosologies and Indexes of Fevers, and of Constitutional, Cutaneous, Nervous, and Mental Diseases. By Thomas Laycock, M.D., &c., Professor of the Practice of Medicine, and of Clinical Medicine, and Lecturer on Medical Psychology and Mental Diseases in the University of Edinburgh. Second Edition. Sm. 8vo. pp. 403.

The publication of the first edition of this work supplied a great need to the student of medicine. In it, for the first time, an attempt was made to remedy a fundamental defect in medical teaching—a defect to which may be largely traced the gravest evils which have beset physic. At all times a source of immeasurable mischief, this defect at the present time is more especially to be dreaded and guarded against. The defect in question is the absence of any sufficient provision by which the medical student might attain to a mental culture and discipline suited to his special and immensely wide spheres of knowledge and labour. In this work Dr. Laycock strove to teach, in what manner

this much-needed culture and training may be attained. He accomplished his difficult and delicate task so successfully, that the work at once took a foremost place amongst medical classics. Of all his works none perhaps will have conferred a deeper and more lasting benefit upon the study of medicine in Great Britain than this student's *Orgaron*, and none, perhaps, will add a greater lustre to the teaching of the University of which he is so distinguished an ornament.

Dr. Laycock tells us that he penned the work "to guide and assist the zealous medical student on the one honourable and certain, but difficult road to professional distinction and success." No student can afford, if he would be just to himself and his profession, to neglect this aid and guidance.

The second edition of the work is nearly double the size of the first, but with little comparative increase in price, although handsomely got up. It is divided into two parts, the one on principles and methods of observation; the other, entirely new, constituting a guide to professional reading and classification of facts. The various mental processes involved in the accurate observation of diseases are described in the simple and familiar style of a lecture. The nature and uses of theories in practice are set forth, and the fallacies to be avoided in judging of the causes of disease, and the effects of remedies are indicated. Amongst the practical points specially and originally treated, we find the natural order of disease as illustrated by the laws of vital periodicity, the physiological diagnosis of constitutional morbid states; the fallacies and difficulties of therapeutical inquiries; the rules for conducting statistical inquiries according to the numerical method, and an exposition of the analogical or philosophical method. Professor Laycock has strong claims to write authoritatively on these important subjects, having been well known for many years as a practical and successful student of them all. The lecture "on the order of succession of morbid phenomena," is a practical summary of his inquiries into the laws of vital periodicity, and that on the clinical observation of constitutional morbid states, supplies a great want in medical literature—namely, scientific and precise definitions of diatheses, such as the strumous, syphilo-strumous, gouty, atheromatous, which are not to be found in practical works. Professor Laycock's early experience and labours in sanitary inquiries enable him to estimate rightly the value and deficiencies of medical statistics. This first part cannot fail to be useful as a book of reference to every practitioner who desires to observe and make public the result of his observations, for even in the shortest report of "a case" to the journals, or the composition of a paper to be read at a society, a knowledge of these principles and methods will be found essential.

The second part is a highly condensed classification of the most important diseases. That of fevers is a complete summary of all our most recent knowledge combined with the author's special views. It includes numerous varieties of the following: general fevers, endemic fevers, epidemic fevers, the exanthemata, fevers allied to the exanthemata, profuse fevers, including every kind of leprosy and syphilitic disease and epizootic fevers. Amongst these last we observe "Trichinia—fever of a typhoid and rheumatic character, with muscular inflammation, due to the Trichina spiralis," the parasite of "measly" pork. Amongst constitutional diseases we observe that the fibroid, osseous, and fatty have a place, together with "constitutional discolorations" or "chromatosis." The classification of these diseases is preceded by an exposition of their pathological anatomy and etiology. It contains a new order of skin diseases named *figurate*, which "includes those in which the cause of disease multiplies locally in the cutaneous tissues, and spreads symmetrically so as to assume a determinate outline or figure." In like manner we find the classification of diseases of the nervous system preceded by an exposition of causes. Of these there are four orders, viz.: Tissue-nervous diseases or *trophesiæ;* motor-nervous diseases or *kinesiæ;* sentient nervous diseases or *æsthesiæ;* and mental diseases and defects, the *vesaniæ*. Dr. Laycock has "formed the class, *trophesiæ*, to find a distinct place for the new and important group of diseases of the small arteries, capillaries, and tissues, which are primarily dependent upon changes in the nervous system, and thus facilitate the study of them."

The volumes end with a classification of mental diseases "according to a method not hitherto attempted, and based on the author's long continued researches." It includes all kinds of mental deficiencies, as well as of diseases and disorders of the mind, and is a sort of index to them. It will be seen from this brief summary of the contents of this book that it is a book of reference for general use by the practitioner of whatever class or specialty.

Obscure Diseases of the Brain and Mind. By Forbes Winslow, M.D., D.C.L., Oxon. Third Edition, revised. London: Robert Hardwicke.

From the large experience of Dr. Winslow—an experience now extending over upwards of twenty-five years—the Profession anticipated in the publication of this volume a very valuable and instructive work on brain disease; a work which throw a vast additional light upon the very obscure subject which he has made his especial study. It is needless to say that expectation has not been disappointed, as a more original publication has never been issued to the medical world. As the title indicates, this volume is not an exposition of the ordinary and well-known forms of lunacy when pronounced and patent; but it penetrates into far deeper soil, and turns up a medical substratum hitherto entirely uncultivated. Those who have had any experience of lunacy know but too well that its curability depends entirely upon the stage at which treatment begins. Where the lunacy has only just declared itself, full 75 per cent. of cases are cured; where, on the other hand, it has been of long standing, the average cures are not more than 10 per cent. Acting upon this important hint respecting the value of early treatment, Dr. Forbes Winslow has evidently asked himself, "Why wait until the mind is actually thrown off its balance? There must be early warnings which tell of the coming catastrophe, and if we can clearly recognise these, our chances of reducing the number of incurable cases will be still further increased!" The thought was logical, and has been well elaborated in the volume before us. By penetrating deeply into the symptoms which invariably go before a mental overthrow, Dr. Winslow has brought to light a mass of morbid phenomena of mind which was before completely hidden to the medical eye. The careful gardener when he sees any abnormal appearance of a flower or a leaf, at once penetrates to its origin, investigates its nature, and at once removes the cause. Dr. Winslow in this volume has pointed out the same course of action. Long before mental disease actually declares itself, the mind through its agents, the five special senses—those delicate tests of a healthy sensorium—give out some notable signs of the coming trouble. The classification of these indications—nay, the very indications themselves—in many cases we owe to the study and great experience of Dr. Forbes Winslow. The portion of the volume devoted to the elucidation of the morbid phenomena of memory, motion, sleeping and dreaming, is devoted to the same end, viz., the furnishing of indications of diseased functions, which if not noted and treated medically are but too apt to degenerate into diseased organization. To seize the moment before this fatal transition has taken place is indeed the object Dr. Winslow evidently aims at in his practice, and the value of this volume is that it points out the means of doing so to others. That it will prove the text-book of the Profession in cases of "Obscure Diseases of the Brain and Mind," we have no doubt. The number and the variety of the cases afforded in illustration of the incipient symptoms leading up to marked cerebral derangement, are most valuable in a professional point of view, and indicate in the clearest manner the large grasp Dr. Winslow has taken of his subject, and the labour he has devoted to it. Since the days of Abercrombie no volume has appeared touching the morbid workings of the intelligent faculties

which at all approaches Dr. Winslow's work, and certainly no medical volume that we are acquainted with is written in a more charming manner. The third edition we see is much more full and complete than the earlier ones, and it fully deserves the great success, both at the hands of the Profession and the philosophical public, which it has won for itself. That it is still destined to run through many more editions, there can be no question.

PROLAPSUS UTERI—RUPTURED PERINÆUM.

Abstract of Clinical Lecture, by T. W. NUNN, Esq., delivered at the Middlesex Hospital,

Mr. Nunn remarked that in the majority of cases in which he had performed Mr Baker Brown's operation for ruptured perinæum in the hospital, the malady for which the patient had applied for relief, was prolapsus of the uterus. Mr. Nunn, stated that he some time previously to the subject of ruptured perinæum being so much studied (and he thought that thanks were due to Mr. Baker Brown, who first prominently brought the matter before the Profession at the Westminster Medical Society, where he (the Lecturer) had himself heard experienced accoucheurs maintain that ruptured perinæum was a very rare accident), had in the pages of the 'Lancet' advanced the opinion that prolapsus of the uterus was due to a falling of the *floor* of the pelvis, and that a very important part of that floor was constituted by the *levator ani.* Since, however, his attention had been specially called to cases of ruptured perinæum, and he had found that partial rupture of the perinæum was an exceedingly common injury, he had in some measure been compelled to modify his opinion as regards the cause of prolapsus, but was at the same time strengthened in his physiological views as to the natural support of the uterus, namely, that it depended upon the *due tension* of the pelvic floor.

"What is called the perinæum in the female," said Mr. Nunn, "is in reality a great transverse elastic band, or rather girder, stretching from one natural limit of the outlet of the pelvis to the other, and occupying the space between the rectum and vagina, and upon this band the pelvic viscera immediately rested. The destruction of this band by the laceration of its component tissues in the median line takes away from the levator ani its power of supporting, and at the same time deprives the sphincter ani of its anterior '*point d'appui*,' thus the anus is dragged backwards, and rectocele induced,—as was seen in a case placed under my care by Dr. Henry Bennet, in which rupture of the perinæum had not only allowed the bladder to become prolapsed, but also the lower two inches of the rectum, so that defæcation was impeded." Mr. Nunn adverted to this case, which was admitted into Regent ward, and was operated on in the usual way with good results.

As regards the steps of the operation and management of the case "For a completely satisfactory result, it was necessary in making the denudation of mucous membrane; to do this with sufficient freedom, as upon the thickness and solidity of the new perinæum the required tension depended. It is not requisite to retain the catheter in the bladder more than twenty-four or thirty-six hours, and this even as a matter almost of convenience. It is not requisite to let the deep suture remain for a much longer period, neither is it desirable to draw these too tight as it is obvious that if drawn tight they must have a tendency to cut out. It is not advisable either to feed highly or stimulate freely, or give more opium than sufficient to lock up the bowels. It is most essential that the patient should be kept perfectly quiet, and not allowed, without assistance, to even turn in bed. It is of great importance where any inflammatory engorgement of the uterus and uterine neck exists to reduce this as far as possible, before operating, as the weight of the womb under such circumstances acts very prejudicially on the newly united perinæum. It is of equal importance after recovery from the operation that an accurately adjusted perineal bandage should be constantly worn, since relapses of procidentia are in most instances due to the neglect of this and over exertion of the patient."

REVIEW OF THE PERIODICALS.

(Continued from page 12.

THE 'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.

Mr. Bouchut gives the name of phreno-glottism to the spasmodic and intermittent convulsion of the glottis and diaphragm occasionally observed in new born or very young infants of nervous, weak, or ricketty constitution. This affection has been denominated thymic asthma, Millar's acute asthma, infantile asthma, internal convulsion, laryngismus stridulus, and spasm of the glottis, the latter being the term adopted in an excellent thesis on the subject by Dr. E. Garcia Wich, of Montevideo.

An infant, aged five months, who since the beginning of January was subject to spasmodic attacks, was brought to Mr. Bouchut's consultation on the 6th of April last year. The parents stated that the child was born after protracted labour, that the trunk had been expelled before the head, and that the latter had ever since remained large and somewhat irregular in shape. In January, convulsions of the muscles of the face has been observed, causing a kind of painful *rictus* attended with squinting. Transitory and irregular attacks of suffocation followed, gradually increasing in violence and frequency. On the 12th of February an extremely severe paroxysm took place; as many as fifteen relapses occurred in the twenty-four hours each fit lasting from 20 to 100 seconds. The attacks assumed two distinct forms: in one they were characterised by *suffocation*, sudden difficulty of breathing, and frequent gasping for air; the face became pale, the entire body was agitated, and the child was unable to cry out. After a short interval some colour was restored to the countenance, and several sighs followed by screams ensued. These fits were transient. In the other form, which the parents called the *accidents*, the fit was ushered in by a short sharp scream, followed by several prolonged moans; the head was thrown back, and the child seemed to be under the influence of a distressing dream. The breathing then became slower, the face was painfully convulsed, the pupil expanded, and the eyes appeared ready to start out of their sockets. The sclerotic assumed a blueish tinge, and the swelled and blackened tongue protruded from the gaping mouth. Previous to this period of asphyxia, the infant's body and limbs were rigid and the arms thrown out. As soon as asphyxia set in the muscles relaxed, and the child returned to consciousness with a sob. This condition was followed by violent epileptic convulsions, and the most alarming spasmodic contractions of the muscles of the face and extremities.

In the intervals of the paroxysms, the child was in appearance well and lively, although its tongue seemed to have suffered, and some slight convulsions of the face were occasionally observable.

When Mr. Bouchut first examined the child, he ascertained the presence of the symptoms of rachitis, but of no other organic disease whatever. From the account given by the parents, he surmised the case to be one of laryngismus stridulus, but as this was merely a conjecture, the professor confined himself to the treatment of the only apparent disease, rachitis, and prescribed one table-spoonful of cod-liver oil every morning, and at one meal in the day a pinch of phosphate of lime.

After an interval of one month, the child was again brought to the hospital; his condition had undergone no change, and during the consultation, a slight attack came on which left no doubt as to the true nature of the case and the existence of a neurosis involving simultaneously the diaphragm and larynx.

Mr. Bouchut considers phreno-glottism as a very serious disease. Dr. Salathé, however, who has written an interesting treatise on the subject, asserts that out of twenty four children whom he has attended for the affection, he lost but two, and conceives that he owes his success to the exhibition of musk. Mr. Bouchut thought himself therefore justified in testing the value of the remedy, and has prescribed the following mixture to be taken in dessert

spoonfuls, without discontinuing the use of the phosphate of lime.

℞ Moschi, gr. iij. ss.;
Mist. acaci, æ, ℥ij ss.

During the four ensuing days no nocturnal attacks were observed. During the day a single paroxysm supervened, equal in intensity to those which had preceded; no similar improvement having occurred for three months, some slight hopes were now entertained that the medicine was conferring real benefit, and it was accordingly persevered in.

Mr. Garcia Wich undertook to visit the patient and report on her progress, and remarked that the fits of asphyxia had entirely ceased under the influence of the musk, but that the transitory attacks of oppression attended with slight cyanosis, and convulsive gasping, which from the earliest appearance of the disease recurred four or five times in the night, and as often in the day time, were in no respect modified by the treatment. He nevertheless recommended the mother to persist in the use of the musk, which was continued, interrupted, and resumed, with or without syrup of cinchona, cod-liver oil, and phosphate of lime; various circumstances interfered with the regular prosecution of the treatment, but at last two incisors were cut, and at the date of Mr. Garcia's last visit, on the 2nd of October, two months had elapsed without any disturbance whatever of the respiratory functions.

Mr. Salathé exhibited the musk, either in powders half a grain daily in four doses, or in an ounce mixture containing one grain, a tea-spoonful of which was given every hour. This practitioner increased or diminished the dose according to the requirements of each case, but persevered in the use of the remedy for some time after the symptoms had disappeared. He remarked that the drug seemed to display greater efficacy in the case of weak infants, who are better able to bear the action of stimulants. In vigorous children, in whom cerebral congestion might be apprehended as a consequence of violent convulsions, he prefers the exhibition of oxyde of zinc, recommended by Baudelocque, Odier, and others, in gradually increasing doses from two grains to fifteen in syrup or preserves.

This result suggests an inquiry into the share of the musk in the cure of the disease. But even admitting that the termination of a crisis due to the evolution of the teeth, combined with the exhibition of remedies calculated to remove the complication of rachitis, may have been instrumental in relieving the neurosis, it would obviously be unfair to overlook the fact that the musk checked and mitigated considerably the paroxysms. In seven of Mr. Salathé's cases, the symptoms were merely alleviated, whereas in fifteen others a complete cure was effected in the course of a few days.

GENERAL CORRESPONDENCE.

MERCURY IN SYPHILIS.

To the Editor of the Medical Circular.

SIR,—Will you allow me space in your journal to correct some inaccuracies which have crept into the report of the debate on Dr. Drysdale's paper, read before the Harveian Society on 29th November last.

In the MEDICAL CIRCULAR of 16th December, p. 354, it is stated, "Dr. Sisson repudiated the base doctrine of some, that the cure of venereal diseases was unimportant, because they were a Divine chastisement of vice." Again, p. 355, "Dr. Sisson had entered his protest against the doctrine of some, that venereal diseases were &c." I beg to say I neither intended that my remarks should, nor do I believe they will, bear any such construction. The exact words I used were these: "I have made no mention of those practitioners who are indifferent about any treatment for syphilis, believing it to be a just punishment for man's transgressions, for to act consistently with such an opinion is tantamount to relinquishing the profession, since most of 'the ills which flesh is heir to,' arise from our own acts of omission or commission." Inferring thereby that there would be no patients for them to treat.

In his reply, Dr. Drysdale is reported to have said, "The child spoken of by Dr. Sisson as benefited by mercury, had died." From this it would appear as if the child had been treated by me; but it was Dr. Drysdale's patient, and the case was communicated by him to the 'Medical Times and Gazette,' of 11th July last. I stated that by this case Dr. Drysdale had unwittingly shown what he denies, that the remedial action of mercury is prompt. He says the child died. Will you allow me to ask him of what?

I am, &c., R. S. SISSON, M.D.
3 Warrington terrace, Maida Vale, W.
24th Dec. 1863.

Births, Marriages, and Deaths.

BIRTHS.

DUNCAN,—On the 19th ult., at Upper Gower street, Bedford square, the wife of Dr. H. Archdeckne Duncan, of a son.

HARLEY.—On the 28th ult., at Harley street, the wife of G. Harley, M.D., Professor of Medical Jurisprudence in University College, of a son.

HELSHAM.—On the 29th ult., at Grove Villa, Loughborough road, Brixton, the wife of Dr. Hector Helsham, F.R.C.S., of a son.

WAY.—On the 15th ult., at Daniel street, Portsea, the wife of Frederick W. Way, M.R.C.S., prematurely of a daughter, still-born.

WILLIAMSON.—On the 27th ult., at Quality street, Leith, the wife of Thos. Williamson, M.D., of a son.

MARRIAGES.

SEATON—SPRAGUE.—On the 24th ult., at Kimbolton, Hunts, the Rev. J. Montague Seaton, M.A., Second Master of Cheltenham Juvenile Proprietary School, to Madeline, eldest daughter of Charles Sprague, M.R.C.S.E., of Kimbolton.—No Cards.

SYSON—KEELING.—On the 30th ult., at St. Peter's Church, Blackley, Edmund John Syson, L.R.C.P.Ed., of Wath-upon-Dearne, to Sarah Frances, eldest daughter of the Rev. W. R. Keeling, M.A., Rector of Blackley.—No Cards.

TOLLER—BROWN.—On the 29th ult., at the Parish Church of St. Mary's, Scarborough, Ebenezer Toller, Esq., Medical Superintendent of the Glocester County Asylum, Wotton, near Glocester, to Mary Elizabeth, youngest daughter of the late Wm. Brown, Esq., Solicitor, of South Shields.—No Cards.

DEATHS.

BOOTH.—On the 25th ult., at Gower street, F. Booth, M.D., aged 72.

DANIELL.—On the 24th ult. at Newport-Pagnell, Henrietta, the wife of Edward Daniell, Esq., aged 66.

IVES.—On the 15th ult., at Daniel street, Portsea, Anne Ives, the wife of Frederick W. Way, M.R.C.S., and second daughter of Edmund Ives Palmer, Esq., of Wade Court Manor, Warblington, Hants, aged 23.

JONES.—On the 18th ult., at Chesterfield, Thomas Jones, F.R.C.S.E., aged 46.

LEWIS.—On the 28th ult., at Ryde, Isle of Wight, David Lewis, M.D., aged 65.

STATTER.—On the 28th ult., R. Dover Statter, M.R.C.S.E., of Mount Pleasant, Liverpool, aged 38.

WHEELER.—On the 26th ult., at Shirley Lodge, Southampton, C. W. Wheeler, L.S.A., aged 71.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, December 24, 1863:—Alfred Square Cooke, Gloucester; Paulin Martin, Abingdon, Berks; Thomas Theodore Steward, Wolverhampton; William Hanks, Snaith, Yorkshire; Samuel Edward Walker, Warwick; John Robert Ruddock, Leeds; William Henry Disen Meuce, Cambridge; Na-

thaniel Levett, Grosvenor-place School ; Philip John Simpson, Gower street, Bedford square.

The following gentlemen also on the same day passed their First Examination :—David Webster Tomlinson, St. Mary's Hospital : Josiah Paull, St. Bartholomew's Hospital ; Charles Edward Martin Shaw, St. Bartholomew's Hospital.

MARRIAGES OF CONSANGUINITY.—M. de Cricq Cassaux, with a view to refute the arguments lately brought forward to prove the danger of marriages amongst relations quoted at the last sitting of the Academy of Sciences the example of the ancient kings of Persia, who, since the time of Cambyses, had been in the habit of marrying their sisters, and even their daughters, and yet produced a very fine race.

THE CASE OF SUPPOSED MURDER IN PARIS BY A MEDICAL MAN.—The physician to whom we alluded last week, and who is in custody under suspicion of foul play upon a lady whose life he had insured for 22,000*l.*, is a homœopath. He belongs to the nobility. and must be very young, and his diploma is dated 1854. It is reported that the autopsy of the young lady has been made, and that no poison whatever was found.

PRISON DIETARIES.—At the last weekly meeting of the Society of Arts, Dr. Edward Smith read a paper "On the Value of Foods to the Working Classes." Mr. Chadwick, in reference to prison diet made a comparison between the results of the diet establshed in sixty gaols. In 20, where the diet was the lowest, 188 ounces of solid food being allowed, the per centage of sickness was 3, deaths 1½ per 1,000 : in 20 gaols where an intermediate dietary from 213 ounces of solid food was adopted, the sickness was 18 per cent., and the deaths 3 per 1,000 ; and in 20 gaols with the highest dietary, 228 ounces per week, there were 23½ per cent. sick, and the deaths were 4 per 1,000.

ABERDEEN INFIRMARY.—The medical students of the University of Aberdeen are about to give two entertainments, chiefly vocal, at the Music Hall, in aid of the funds of the Infirmary. A great success is anticipated. Last year the students gave a dramatic entertainment, which was eminently successful.

VENTILATION.—At the last meeting of the Croydon Board of Health it was resolved, on the recommendation of the chairman, that, in order to secure proper arrangements for the ventilation of dwelling-houses, a copy of the bye-laws, so far as related to the building of houses, should be given to every builder on his depositing the plan of a new house at the office, and also that the attention of the people should frequently be directed to the subject of ventilation. A very prudent course of proceeding, which reflects the highest credit on the Croydon Board of Guardians.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN. — The next meeting will take place on Wednesday evening, the 6th Jannary, at Eight o'clock. The Chair will be taken at half-past Eight precisaly. The following papers will be read :—"Note on the Root-Bark of Calisaya." By John Eliot Howard, F.L.S. "Note on *Cassia moschata*." By Daniel Hanbury, F.L.S. "On Goa Powder." By Mr. David S. Kemp. Note on the Recovery of Essential Oils from their Watery Solution." By Mr. T. B. Groves. Thompson's Patent Bottles, and Thonger's Patent Label for the Prevention of Accidental Poisoning, will be exhibited at the Meeting.

MEDICAL CORONERS.—The office of coroner for the Stafford division of the county of Stafford is vacant by the death of Mr. Collis. We understand that Dr. Wollaston, of Stafford, is a candidate. The medical practitioners of the district have it in their power to place Dr. Wollaston at the head of the poll. That they will do their duty no doubt can be entertained.

POISONING WITH SALTPETRE.—An inquest has recently been held at Oswestry on a man named Wilson, who had been supplied by a chemist with several packets of saltpetre in mistake for Epsom salts. It appeared that these two articles were kept in adjoining drawers in the shop. Verdict, Accidental death. Is it possible that the jury separated without passing some censure upon the druggist who supplied the poisonous dose ?

MR. LAWRENCE'S ELECTION AT PARIS.—At the meeting of the Academy of Sciences of Paris on the 21st of December last, the members proceeded to the election of a foreign correspondent in the section of medicine and surgery, in the place of the late Sir Benjamin Brodie. Mr. Lawrence obtained forty-five votes and Dr. Simpson one. Mr. Lawrence was therefore declared duly elected.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—At the Quarterly Court of Governors of Addenbrooke's Hospital, held on Monday last, Lord Hardwicke in the chair, the question of adopting Dr. Humphry's plan with regard to the erection of a new hospital was again discussed ; and it was eventually agreed to refer the matter to the Committee for them to obtain from Mr. Wyatt a specification and working drawings, and then to apply to four substantial contractors for tenders as to the cost. A special meeting will be called to consider the subject.

MEMORIAL TO THE LATE DR. ENGLEDUE.—The friends of the late Dr. Engledue have recently placed in the committee-room of the Royal Portsea, Portsmouth, and Gosport Hospital, an admirably executed and correct portrait of the deceased as a token of their appreciation of the services rendered by him to that institution.

THE NORWICH INFIRMARY ASYLUM.—At a late special meeting of the Norwich Town Council a report from the committee appointed to consider the necessity of providing an asylum for pauper lunatics was received and adopted, though by a small majority. The Council have by this decision confirmed the arrangement to purchase the leases of the premises of the Norwich Infirmary together with the furniture and fittings.

APPOINTMENTS FOR THE WEEK.

Wednesday, January 6.

Operations at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m. ; University College Hospital, 2 p.m. ; Obstetrical Society of London, Annual meeting for election of officers, &c. Papers by Dr. Day and Dr. Grailly Hewitt. President's address, 8 p.m.

Thursday, January 7.

Operations at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m. ; Great Northern Hospital, King's cross, 2 p.m. ; West London Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m. ; London Surgical Home for Diseases of Women, 2 p.m. ; Royal Institution, Professor Tyndall, F.R.S., "On Electricity at Rest and Electricity in Motion," Juvenile Lectures, 3 p.m. ; Harveian Society, Anniversary, President's address, election of officers, and conversazione.

Friday, January 8.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, January 9.

Operations at St. Thomas's Hospital, 1 p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; King's College Hospital, 1½ p.m. ; Charing-cross Hospital, 2 p.m. ; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m. ; Royal Free Hospital, 1½ p.m.

Monday, January 11.

Operations at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m. ; Metropolitan Free Hospital, 2 p.m.

Tuesday, January 12.

Operations at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

EXTENSIVE SCALP-WOUND WITH SLIGHTLY DEPRESSED FRACTURE OF THE SKULL.

J. B., æt. forty-five, a labourer, admitted April 17, 1863.

History.—Whilst wheeling some débris from a house at the height of fifty-two feet from the ground, the scaffolding upon which he was, gave way, and he was precipitated that distance, falling upon his feet first, but immediately afterwards upon the back of his head, which came in contact with some iron spikes. He became insensible, but recovered in a few minutes.

On admission there was found an extensive wound of the scalp, reaching from two inches above the left ear, across the vertex to about three inches above the right ear; from these points it reaches back on the left side about three or four inches. The whole of the scalp included in these measurements was entirely stripped off the bone and could be detached downwards and backwards to the occipital protuberance.

There was a good deal of hæmorrhage at the time of admission, necessitating the tying of several of the smaller vessels and an enlargement of the wound in order to reach the deeper. Mr. Erichsen had the wound brought together by means of three silver-wire sutures, after which cold was applied, and, there being no symptoms of cerebral disturbance, there was no interference with the depressed bone; the site of the depression was an inch below the anterior superior angle of the left parietal bone and extended for about an inch and a half.

The patient was ordered the following pills to be taken at once:

℞ Calomel, gr.iv.;
Extracti Coloc. co. gr. vi; in pil. ij., et haustus domest: post horas tres.

April 18th.—Has had a good night; there are no cerebral symptoms; pulse 108, firm and regular; bowels opened by medicine; skin, moist and perspiring.

19th.—Slept well last night; wound healthy and discharges pretty freely; bowels open; is thirsty and slightly feverish; pulse 108; no cerebral symptoms.

20th.—Has a cough; there is no pain in the head, nor any indication of cerebral symptoms; the discharge is quite healthy; pulse 100; bowels open; ordered mistura effervescens.

21st.—Cough is troublesome; wound healthy; there is some bagging of matter at the occipital extremity of the wound, whence, an incision being made into it, there flowed away some pus to the very great relief of the patient.

22nd.—Passed a very good night; cough is still troublesome; discharge is quite healthy.

25th.—The wound has united in its centre to the extent of an inch and a half, and throughout is quite healthy; the cough is better; sleep is good; pulse has fallen to 96, and is full, as well as strong.

28th.—Wound is united at two or three points; health is good; bowels being costive is ordered

℞ Calomel, gr.iij.;
Extract. Coloc. co., gr. viii.—in Pil. ij.;
Et haust. sennae, ℥j. cras. mane.

May 2nd.—Wound granulating from the bottom at the point where it gaped so widely, and is perfectly healthy throughout, nor in the discharge is there any deviation from what it should be, the general condition of the patient being unimpaired.

May 24th.—All through there have been no unfavourable symptoms, and the patient being perfectly recovered is discharged.

[*From the Case-Book of* JAS. YEARSLEY, M.D.]

THE ARTIFICIAL TYMPANUM IN CASES OF PERFORATE MEMBRANA TYMPANI.

The triumph of Aural Surgery is in no instance more striking than in the case of a patient who presents himself before you so deaf, and with such an amount of disorganisation of the tympanum, as would have disposed you a very few years ago to come to the conclusion that nothing could be done. In 1842, I had discovered that such cases were not altogether hopeless, and in 1848 I published in the columns of the 'Lancet' the very simple means by which we might effect amelioration, if not cure, in such cases. It is a singular observation to make, but it is no less a fact, that every aural practitioner who holds the same views as myself, as to the nature and causes of deafness, must prefer to see, in all cases of a certain standing, structural disorganisation of the membrana tympani, rather than that the membrane should be patent and imperforate. His eye will brighten when he hears of symptoms which indicate demolition of the aural apparatus, and when by inspection he discovers the extent of the structural disease he knows that his chances of affording relief are commensurately increased.

The following case will serve to illustrate the point for which I am contending—namely, the more disease there be, the better chance there is for the patient.

Mr. E., is a teacher in a school, and had been deaf for twenty-five years, so deaf that he had lost many situations. On examination of the ear, it was found that both membranes were perforated, and the tympana altogether disorganised; the otorrhœa, characteristic of, and usually attendant on these cases, had subsided for many years, though he perfectly remembered the ear-ach, and the "gatherings inside at the beginning of the deafness." When the discharge ceased, the hearing greatly diminished, and the temporary improvements usually attendant on these cases he had not experienced for many years. He had gone the round of aural surgeons, and had been told by one of them, who had unmercifully blistered him, that nothing more could be done for his relief.

The wetted cotton in this case proved eminently successful. The effects are best described in the patient's own words:—

"In less than five minutes you made me hear as I had not heard for at least a quarter of a century. I never shall forget the change. When I left your house and went into the streets, I was almost bewildered by the sound of voices, footsteps, and the different vehicles. I thought every one was shouting and making as much noise as possible. I was afraid almost to cross the streets, for omnibuses and carriages which were at a considerable distance seemed to be quite upon me.

"When I reached home and went into the school, it was with the greatest difficulty that I could remain there; over and over again I was tempted to beg permission to leave for that afternoon, because the sound of the pupils' voices, and even the rustling of their clothes, annoyed me so much. At present I am accustomed to it, but still find it very hard to bear.

"Now that you, Sir, have taught me to put in the cotton, I can make myself hear even better than you did. I can perfectly hear all ordinary conversation, sermons, &c. I

could not have believed that I had been so deaf, so great is the difference I experience."

Nothing can be more interesting than the various descriptions given by the patients of their new perceptions under the influence of this singular remedy—one is taken by surprise in hearing for the first time within remembrance the chirping of birds *outside a window*, a noise which he thought must be in his own head as a symptom of his disease—another is going to cut wood in the forest, and is frightened by a noise in his head equal to a loud cataract, he discovers that it is the rippling of the brook by the side of which he had worked for years, and never heard it before.

[*From the Case-Book of* Mr. J. ZACHARIAH LAURENCE. *Reported by Mr. Robert Moon, House-Surgeon Surrey Ophthalmic Hospital.*]

A CASE OF AMAUROSIS DEPENDENT ON EFFUSION INTO THE ORBIT.

Elizabeth P., aged eleven years, a very precocious and intelligent child, presented herself at this Hospital on the 26th of August, 1863, stating that she was unable to see with the right eye. A fortnight previous to this time she suddenly felt a "pricking pain" in the right eye and right side of the forehead, and on covering the left eye she discovered that the sight of the right eye was "dim." From that time she continued at intervals to complain of the pain in the eye and supra-orbital region, which would last for about fifteen minutes at a time, or occasionally for several hours, the sight becoming visibly less day by day, till, at the time of her applying at the Hospital, she could barely distinguish light from darkness.

The appearances which the affected eye presented were as follows:—It was more prominent than the other (left) eye, was slightly divergent, and somewhat drawn up. The power of inversion and eversion of the globe was diminished, and on closing the left eye the pupil of the right (which before had been of a normal size, in a bright light) became suddenly dilated to a very considerable extent. No abnormal condition was discoverable with the ophthalmoscope, beyond a slightly-increased vascularity, which was common to both fundi. This tended to strengthen Mr. Laurence in his first impression, that the seat of the mischief was extra-ocular, more especially as on further investigation, it appeared that for three years she had been subject to periodical attacks of violent pain in the head, which he always referred to the vertex and forehead. The pain was so severe as at times to make her "cry out dreadfully" with the agony. She had not suffered a recurrence of the pain during the two months previous to her coming to the Hospital. Mr. Laurence expressed, as his opinion, that the blindness was caused either by the presence of a tumour behind the eye, or by effusion within the orbit or cranium, a diagnosis which the previous and after history of the case appears fully to have justified.

She was ordered two leeches to be put on the right temple, and a powder containing two grains of grey powder and three of rhubarb, to be taken three times a day. As within a few days she was attacked by a return of the pain in the head of a most distressing character, accompanied by obstinate constipation and vomiting, she was unable to leave her bed, and from that time was attended by Mr. Jeffrees, of Kennington, under whose care she has since remained. The constipation continuing, Mr. Jeffrees was compelled to remove several scybala, after which the head symptoms were less severe, and the vision of the right eye began to improve.

On the 8th of September she was able to count fingers quite well, but the centre of the field of vision was still perfectly dark. She was now again examined with the ophthalmoscope, but nothing abnormal could be found. When last seen, on the 20th of November, the vision a movements of the globe were perfect, and her general heal was very greatly improved.

Effusion, either intra-cranial, or intra-orbital, was doub less the immediate cause of the temporary amaurosis, producing paralysis of the sentient structures of the e As the effusion became absorbed, so the pressure w diminished, and the vision gradually returned.

[*From the Case-Book of* MR. GASCOYEN. *Notes furnished by J. G. de Gorrequer Griffith, House-Surgeon to the Dean street Lo Hospital.*]

S. W., æt. twenty-nine, of fair complexion and spa habit was admitted into the house on Oct. 8th, 1863, f Rupial patches on the abdomen, thorax, neck and limbs.

History.—Entered the Service in 1852 as a marine; 1857 contracted a sore at the very extremity of the peni near the urethral orifice, which he states to have been hard for this he was treated, as far as he knows, without a mercury; certainly the gums were never made tender, t chancre was healed in about a month; he was detained hospital for about three months, owing to the formation buboes in either groin, and to their having been subs quently opened, so as to allow the escape of the lar quantity of pus contained in them. Twelve months sin after a heavy "bout" of drinking which he had kept u for about a week, and which had lowered him very muc there appeared "pimples," first on the face and then o different parts of the body, from these matter came out an scabs formed over them, when the latter fell off they le the skin on the face sore and red, on the body in som parts at least, ulcerated. The ulcers were treated by sars parilla internally, and as a local application, some kind white ointment was used.

All the spots except one on the forearm, and another o the neck had disappeared before last May, and he remaine quite free from them, *till he fell into bad health* in last Se tember; in the beginning of which month the same eru tion appeared on the left abdominal wall, immediately ov the left crista ilii, then all over the abdomen; the ches face, arms and legs being the last to be affected. Th state he presented on admission, having moreover, nume ous cicatrices of the former eruption, some of which wer and are still of a glistening white, not unlike a large vacci nation mark, others being tubercles of the size of filbert reddish and polished on their surface, of a gristly hardnes and perfectly moveable.

The treatment pursued is necessarily varied, because the obstinacy and rebelliousness of the eruption, whic though it never wholly disappears, fades for a few days, t again break out afresh. Immediately on admission he wa put upon

℞ Ferri pot. tart., gr. v.;
Pot. iodidi, gr. iij.;
Infusi quassiæ, ℥j. t. d. d.

the patches were touched with the Lotio. cupri. sulph. gr. ad. ℥j.

On Oct. 12, he was ordered Ol. morrhuæ in half oz. dos twice daily, as well as to continue the above.

Oct. 24.—Continue the above, but in addition let hi have the mercurial bath every night, gr. x. of calomel bein employed.

On the 31st.—The bath was to be given only every othe night.

Nov. 2nd.—Omit bath.

Nov. 6th.—The following was substituted for the abov mixture:

℞ Iod. pot., gr. iij.;
Liq. hyd. bichlorid, ℥iss.:
Tinct. Opii, ℥v.;
Tinct. cinchonæ, ℥j.;
Decocti ejusdem, ℥j.—ter in die.

This on Dec. 1st, was laid aside for the first mixture, and the following lotion was to be applied to the patches :

℞ Acidi tannici, ʒss. ;
Glycerinæ, ℥ss.—ft. lotio.

Dec. 8.—In addition to this mixture and lotion he was ordered the mercurial bath as previously ; but discontinued it on Dec. 12th.

Dec. 29th.—The mercurial treatment seeming not to agree with him, Mr. Gascoyen has put him upon quinine and cod-liver oil only ; the patches to be washed frequently in the day with the simple lotio. plumbi. The patient is at present progressing favourably.

This case is of especial interest, as illustrative of the fact, that the sequelæ of syphilis may be of an aggravated and obstinate form, even though no mercury may have been administered.

CASE II.—Also under the care of Mr. Gascoyen.

SERPIGINOUS ULCERATION.

T. W., æt. thirty-two, of light complexion and delicate appearance, was admitted on Dec. 3rd, for Serpiginous Ulceration of the thigh.

History.—Was a soldier, and with his regiment went to Gibraltar, in 1854 ; he there contracted a soft chancre on the centre of the dorsum of tbe penis, but was quite cured of it in three weeks, none but simple remedies being employed. In 1861 he had gonorrhœa, and about nineteen months since, on his way back from India, he got a sore on the *right* cheek, just below the ramus of the jaw, another on the *left* upper arm, and a third immediately below the right knee. In May, 1862, he was discharged from the army.

On the day of his admission there was a large serpiginous ulcer, about the size of an ordinary saucer, on the centre, but outer part of the thigh, and another about the size of the palm of the hand over the left trochanter ; as well as the cicatrices of the old "eruption," which he describes as the same now presenting itself in the places just mentioned. He has never taken mercury. Mr. Gascoyen ordered him

℞ Iod. pot, gr. iij. ;
Ammon. sesquicarb., gr. v. ;
Decocti cinchonæ, ℥j.—ter in die.

With one of the ulcers, the smaller, was tried the Lotio. pot. tart. ferri. ʒj., ad ℥iv., to the other, the larger, the Lotio. plumbi., in which there is liq. plumbi. diacetatis, ʒj. ad ℈j. aquæ. So rapid was the amendment of the latter, that the lead lotion was after the first few days used to both ulcers, which healed speedily, and allowed of the patient being discharged cured on the 7th of January.

There have been in our wards for some little time two patients with immense inflammatory thickening of the prepuce, a condition of solid œdema, which makes the organ not alone unsightly, but unfit for the exercise of its generative function ; both have been, and one is still being treated with the local mercurial fumigation every night, or every other night, and by the enveloping of the penis during the day in a piece of lint, thickly smeared with unguent hydrarg. Under this plan of treatment the parts are rapidly improving, the enlargement is being reduced, the hardness becoming less hard, and the entire organ returning to its normal proportions.

ULCERATION OF THE DORSAL ARTERY OF THE PENIS AND HÆMORRHAGE.

G. W., æt. twenty-three, a navvy, of very stout build and of florid complexion, was admitted into the Male Lock Hospital, on Dec. 10, 1863, with a large ulcerating sore on the right side of the glans, involving the corona and the prepuce—with a large open bubo in the right groin, and herpetic eruption on the sides of the trunk.

He states, that about three months since, he contracted the sore on the glans, which has continued to spread ever since, and that a month subsequently the bubo made its appearance. The interesting feature in this case is, that the dorsal artery was opened into by ulceration, and that the hæmorrhage was arrested by putting a pledget of lint well soaked in the muriate tincture of iron into the fissure made by the ulceration, and from the bottom of which the blood welled up—then flexing the glans backwards upon itself ; in which position it was maintained for some hours by strips of lint passed over the glans from before backwards. An attempt was made to seize the bleeding vessel, but no firm hold could be obtained or secured ; hæmorrhage however, has been effectually arrested, nor does there seem any disposition to return, inasmuch as the ulceration has altogether ceased, and the wound, since the hæmorrhage, has taken on a healthy action.

REMARKS ON THE DRACUNCULUS OR GUINEA WORM.

BY DR. G. DE GORREQUER GRIFFITH.

This worm, which has received the name of Filaria Medinensis in addition to those names above written is, of the several varieties of Entozoa, one of, if not, the most troublesome ; often, indeed, endangering, and sometimes destroying, life by the wearing pain, by the exhausting suppuration and by the general irritation and disturbance which demonstrates itself by the attendant characteristic fever. If, however, there be not these extreme sequences, there may be a maiming of that limb, in which the Entozoa has become developed.

Various are the parts of the trunk and limbs which it chooses for its habitation, but it seems to have for the lower half of the body, and of it more particularly the legs, a special predilection. In the cases which have come under my notice, I have found the following order of frequency, as to the site of "pointing," that is, as to the place where the parasite determines, and seeks to effect an opening in the integument for the purpose, no doubt, of discharging its ova or of itself passing out of the body and into a higher organisation : First, the external malleolus ; second, the internal malleolus ; third, the base of the metatarsal bone of the little toe, or the dorsum of the foot : fourth, the inner or outer fossa, which lies between the inner or outer malleolus and the posterior extremity of the os calcis ; fifth, below the head of the fibula ; sixth, on the outer side of the leg and just about its centre ; seventh, the scrotum.

We will take, for purposes of illustration, the case of a patient, in whose leg the worm has fixed itself, and we will describe the subjective and objective symptoms, that are found to obtain. Under the former will arrange themselves a sense of heat, of stiffness, of swelling, an uncomfortableness and intense itchiness in the site of pointing, as well as in the neighbouring articulation—if it be close to the pointing—and in the entire limb : these gradually, or it may be quickly, merge into actual stiffness, pain, swelling, and the other usual local symptoms of acute inflammation ; moreover, in a great number of cases the itchiness, from being limited and almost confined to the site of pointing, diffuses itself over the entire body, and, rebellious to all means employed for its removal or for its alleviation, becomes most distressing. Under the objective symptoms we have, at the very outset of our patient's complaining, a somewhat hard swelling, round and about the size of a common coat-button, very slightly cone-shaped, the base being scarce wider than that part which rises above the level of the surrounding surface ; this, the "phlegmonous tumour" of M. Maisonneuve and the centre of the subjective symptoms, soon grows soft and becomes capped with a vesicle or bleb, owing to the lifting of the cuticle from the cutis by a serous fluid, at first clear, and which allows us to see the subjacent cutis red and raw in its appearance and likewise the head or some other part of the worm, as is indicated by a white speck or line in the centre of this vesicle. Should the bleb

remain for a few days unopened the limpidity of the serum is lost, the fluid entirely altering its character, becoming turbid, somewhat grumous and containing yellowish-white flakes, such as occur in unhealthy abscesses; in white men a blush of inflammation is seen surrounding it, but in the black this is not evident, there being instead an increase in the dark shade of the skin; in both white and black men alike there are puffiness, immediately surrounding the tumor and vesicle and involving the limb for some distance above and below,—edema, as evidenced by distinct pitting on pressure—and leading away from the pointing spot a narrow, winding swelling, which seems to be, and has been, more than once mistaken for a varicose, or even an inflamed vein; on examination, this swelling is found to be very tender, and is of such a peculiar nature, as to convey to our mind the idea of a violin-string being inserted beneath the integument and wound round the leg; sometimes it has a consistence not unlike the hardness of the "vas deferens." This cord-like hardness may precede the appearance of the bulla, and its cause may be hid in obscurity, until the appearance of the latter.

In every case I have been enabled to trace the disease through the several stages, which I have above enumerated, and have, in my own mind, long looked upon it as divisible into firstly, the stage of deposit; secondly, that of incubation, wherein the filiæ are being developed; thirdly, that of the formation of vesicula; fourthly, that of ulceration; fifthly of suppuration and expulsion; and lastly, that of healing.

Through sympathy, the glands, in connection with the affected parts, will become enlarged, hard, tender, or even acutely painful.

The causes assigned for the suppuration are: firstly, the presence of an *inanimate* substance, namely, the *dead* parasite, in the midst of living tissues, which are affected in a manner similar to that occasioned by the use of a seton, or by the presence of any foreign body whatever; with this I cannot entirely hold, since I have seen pus developed in the limb, or part affected, the worm not having been deprived of its vitality; secondly, the pouring out of a poison from the interior of the filiaria; to this supposition some colour is given by the facts, that we find pervading the interior a whitish fluid, that there is the general and harassing itchiness, to which we have before adverted, and that may be explained only by the hypothesis of blood poisoning; thirdly, and I think more probably, it is occasioned by the discharge and development of the ova and the great irritation caused by the enlarging in size and the movements of the young filariae. The tumour at the seat of pointing is, without doubt, produced by the parent-worm seeking thus an exit for the extrusion of its offspring, or for its own emergence into a new and higher kind of development.

This Entozoon, called from its slender proportions the "hair worm," is most frequently half a line to a line or a line and a half in thickness, sometimes even more; while in length it may be twelve feet and upwards; the caudal extremity is round and somewhat club-shaped, the capital being narrower and pointed; the entire worm is highly elastic, semi-transparent, of a yellowish-white appearance, and, when the central canal is filled with the peculiar fluid, supposed to be the cause of so much evil, the shape is round, which however being altered on the expulsion of this fluid assumes a flattened, band-like appearance.

In the young state the worm is cylindrical, with no tentaculæ or any other kind of appendages, and is possessed of immense activity, when it is floating in the fluid, which is, for a certain period, its natural element; nay, more even, when removed from this into water, it preserves for some days the same constant activity of movement.

The proper bed of this parasite is the subcutaneous cellular tissue, but it will not unfrequently be found wrapping and coiling itself around the tendons and nerves, hence occasioning the exquisite pain experienced by the sufferer, as the coils are being disentangled and the worm removed; a pain so severe, that I have seen the stoutest men almost faint under the infliction; at times, indeed most generally, we shall in some parts of its course discover the worm coiled upon itself, and deeply imbedded on the cellular tissue amongst the muscles.

Treatment:—Dr. Daniell, in his "Sketches of the Medical Typography and Native Diseases of the Gulf of Guinea," has it thus, of the native operation for the complete removal:—"A small semilunar incision was first made in the skin to expose the extremity of the worm and moderate pressure used to facilitate its protrusion; it was then seized and cautiously drawn out to the extent of an inch or two inches; two ligatures constructed from the exsiccated fibres of some graminous plant were next applied to that portion of the worm nearest the orifice of the skin, the other part being nipped off; the extremities of both these ligatures were of sufficient length to encircle the limb, round which they were fastened. A young plaintain leaf smeared over with palm oil was then placed over the wound and friction carefully employed with the same oleaginous fluid along the course of the worm. This process was daily performed, and a small portion of the worm regularly exposed, until the whole was gradually withdrawn, a perfect cure being the result."

The method which I have seen practised by the native Indians is very much the same as that described by Dr. Daniell, except that they make no incision into the skin, contenting themselves with merely opening the vesicle or allowing it to burst, seizing the presenting part of the worm, drawing it out from its bed for a little distance, and coiling it round a piece of linen continue the operation from day to day, till none of the parasite remain. Having made fast the piece of linen and the worm coiled upon it, the wound is somemetimes smeared over with some "chunam" paste, or covered with a pledget of cotton, saturated with saliva, in which by a process of chewing has been mixed the juice of the dried betel-nut; either mode of dressing being adopted, the entire is swathed somewhat tightly.

The class of patients in which I have met with this most frequently is the weakly, emaciated, and delicate; and when I have found it in the opposite, that is in the robust and muscular, the subjects were those lascars who had recently come to sea at the close of the "Sou-West," or the beginning of the dry "Nor-East Monsoon." I have never met with a case of it among the Chinese, and indeed they seem to have an exemption from the affection, even when in daily converse and close contact with the diseased, either resident in India or China, or living on board ship.

The treatment which I have adopted, and, at the expense of the least possible suffering, successfully, was as follows:—Immediately on the man presenting himself with the tumour or with the bulla, I made an opening into either and squeezed out, as much of the fluid as I could get to flow away; I then proceeded to knead thoroughly for a quarter of an hour the entire limb above and below the wound, desisting only if the pain became excessive, which I found to be very rarely the case when the kneading was continued steadily and firmly, and the palmer surface of the thumbs employed. This done, and some portion of the worm extruded, a pledget of lint was placed over the wound and over the protruded part of the worm, compresses placed upon the tract of the parasite, and the limb bandaged from the foot upwards to some little distance above the farthest point to which the worm could be traced the wound itself not being covered with the folds of the bandage. The kneading should be performed over as much of the limb as seems to be occupied by the offending cause, nor shall we be very much at a loss as to how far this extends, since it is distinctly traceable by the cord-like feel, which we have mentioned, or by the line of pain and redness, leading, according to the site of the wound, either upwards or downwards. This cord-like feel, especially taken in conjunction with the last two symptoms, is of great value as a means of ascertaining how far the worm has extended itself.

After the bandaging the patient is made to plunge the limb into water as warm as he can bear it, and to keep it immersed for some hours at a time; this being done severa

times during the twenty-four hours, on the next day the pain and swelling will be very much abated, the tension of the integument relieved and an additional part of the worm extruded, a greater length of the remainder admitting of extraction with a facility, which we could scarce anticipate. The same process, as was adopted the day previously, must be again put into practice, and very often it will be found advantageous to extend the opening along the course of the worm, so as to make a larger aperture of exit, and in this manner to hasten the expulsion of the irritating substance; furthermore, when we have ascertained the tract, we may make an opening in its centre down upon the entozoon, divide it and proceed to extract both fragments simultaneously. This plan is especially to be recommended, inasmuch as the cure is effected with so very much less suffering to the patient while he is under treatment, as well as with a very much greater degree of celerity. The simple division of the worm in its centre not alone has the advantage of enabling us to act upon the fragments at the same time, but likewise makes the worm relax its hold, so to speak, of the muscles, tendons and nerves, and as a consequence permits of our removing it with comparative facility. When there are a number of abscesses in the leg in connection with this source of irritation our best plan is to lay each one open, or if there should be a number close to each other, we may make an incision, which would include two or more. At the bottom of each abscess we generally find a knuckle, fold, coil, or series of coils of the worm, and have thus an immediate explanation of the purulent formation and collection. On opening these tumours at the same time that the fluid drains away, there are expelled an immense number of young filiæ, which are to be seen moving rapidly in their proper element.

In some cases instead of adopting the immersion I over the bandage place a hot linseed meal poultice or a hot fomentation cloth and encase all in a sheet of oil silk, so as to keep the affected limb in a constant vapor-bath;—and all these steps should be repeated daily, till no trace of the Dracunculus remain. The process of expulsion is sometimes very tedious in those instances, where the worm has coiled itself around the phalanges.

I hold it to be unnecessary to roll the worm upon a piece of quill, lint, linen, or to dispose of it at all in this manner, neither is it serving any more useful purpose to bind it down upon the integument, on the supposition, that unless such measures be adopted we shall lose sight of it altogether; since this supposition is based on the *erroneous* idea of there being an inherent retractile power in the parasite; this retractility depends not on any active power possessed, but simply on great resiliency or elasticity.

When the scrotum is the site of its lodgment the pain experienced is often most agonising.

The general treatment to be pursued is that best calculated to support the strength of the patient, at the same time that we take precautionary measures against the incessant irritation.

January 1st, 1864.

HOSPITAL REPORTS.

OPERATIONS BY MR. ERICHSEN.

Last Wednesday, in the presence of a large number of spectators, Mr. Erichsen proceeded to operate upon a female for a hard tumour of the left breast. Chloroform being administered, and the fibres of the pectoral muscles being well stretched by drawing the arm outwards and downwards, over the operating table, he made a rapid semilunar-shaped incision running along the lower margin of the breast, and somewhat obliquely across the fibres of the aforenamed muscles, partially lifted up the tumour at this its lower edge; and then making an incision immediately above the breast, so as entirely to circumscribe the mammary gland, as well as the tumour, both incisions were united; he then proceeded to dissect the mass so circumscribed completely away from the muscle. There was no unusual hæmorrhage; the wound was brought together by a few thread sutures, and having placed over it compresses of lint and towels, the entire was then made secure with an ordinary "roller," and the patient was removed.

Mr. Erichsen said, that the nature of the tumour had been rightly diagnosed previously to any operative steps having been taken, and, that, the diagnosis was now fully verified after removal, and after he had made an incision into it; that he had no doubt in his own mind as to its being scirrhus; 1st, because of the woman's age, she having arrived at that period when cancer is supposed most frequently to develope itself;—2nd, from the peculiar hardness of the tumor;—3rd, from its grittiness, when cut through with the scalpel;—4th, from its peculiar glistening white or blueish-white appearance on the divided surfaces,—5th, its striated structure, evident to the naked eye, and caused by intersections with white bands, which are composed of partly new structure and partly of cellular tissue.

The indications for removal in this case were:—the health of the patient had not begun to be impared; there was no glandular complication, nor any cancerous deposit in other organs or parts of the body; the glands of the axilla, and those below as well as above the clavicle were completely free from any appearance which would lead to the supposition of their involvement in the disease; only one breast was the seat of the disease; the tumour was quite moveable, and could be distinctly isolated from the subjacent parts; there was complete absence of tegumentary infiltration and of that peculiar unhealthy, oily and reddish-brown appearance which should, when other evidences are concomitant, warn the surgeon of the danger to be apprehended from any operative interference; the tumour had not taken on rapidity of growth, nor was there any sign whatever of a tendency to cuticular ulceration.

We know that cancer of the breast most frequently occurs in women, and is extremely rare in men. One instance of this disease in the male occurs to our recollection, and, as we are upon the subject, we will mention it; it was that of the late Dr. Bellingham, the eminent Dublin surgeon, who was one of, if not the greatest, advocate for the cure of aneurism by compression, at a time when such a proceeding was not in that estimation which it now gathers around it.

The causes of its greater frequency in women are to be found in the functions—the changes—the sympathies—and the more frequent liability to accident; in referring to the functions of the breasts allusion is made to the office of lactation, and the "draught" or rush of blood to the organ, when the child is put to it for the purposes of sucking; by its changes we mean, not alone this determination of blood at the period of lactation, but the alterations that nature effects, both at the accession of puberty, the development of the menstrual function at the period, and which, in fact, constitutes puberty, and likewise at the climacteric age, when there is a cessation of the wonted activity, a considerable reduction in the amount of blood circulating, causing a thorough lowering of its vitality, and as thorough an alteration in the functions, which it had exercised during the procreative period of the patient's life.

During the time of gestation also the breast is constantly undergoing certain changes, in order that it may be fitted for the office, which it shall be called upon to discharge after the birth of the offspring.

The sympathies of the breasts with other organs, but especially with the generative, and that not alone, when the latter are in a perfect condition of health, but also when they are involved in disease, are too well known to need our pausing here to consider them.

The liability to accident obviously arises from the larger development and prominence in women as compared with men.

The cancerous age—if we may be allowed the term—occurs at the time when there is cessation of the child-bearing functions; now, although cancer of the hard form is most

frequently coincident with the years between the 30th and 50th year of the patient's life, yet it may declare itself at even an earlier age: according to Mr. Birkett, those women who are between 45 and 50 are its most common subjects. The being unmarried, or sterility when married, are by some held to be causes of origin of this affection, while by others the very opposite conditions are supposed to be inductives. We should remember that the number of women who are married if not *de jure*, at least *de facto*, is proportionately larger than those who have in no signification been at all married.

This, we think, would in some measure help to explain the differences of opinion, based upon statistics, as widely different.

The next case on which Mr. Erichsen operated was that of a healthy looking child aged three years, from whom, by the lateral operation, he removed a lithic acid calculus of a rounded somewhat oval-shape, smooth on its surface, and of a dark brown or mahogany colour.

After its removal, in his accustomed manner, in order to obviate any danger of urinous extravasation or infiltration, he introduced into the bladder, through the wound, a gum elastic tube, for the direct transmission of the urine, and had it secured by means of tapes passed round the thighs and fastened to a band placed about the abdomen immediately above the hips.

The following statistics of Mr. Coulson show the periods of greatest danger in this grave operation:—Of 2,972 cases there was one death in every 13, the patients being below 10 years of age; after which, in a range varying from the 10th to the 80th years of life, the rate of mortality is 1 in 9, 1 in 6, 1 in 5, 1 in 4, 1 in 3.65, 1 in 3.23, 1 in 2.71

These tables at once declare how *comparatively* free from danger is this operation in young children; and this may be attributed—first, to the condition of the urinary organs themselves, they being as yet only incompletely developed, and very much less excitable or irritable than in the adult subject; and, secondly, to the quality of the fluid contained in the bladder; since in exact proportion to the amount of debris contained in this fluid is the amount of irritating power possessed by it, which is altogether dependent upon its acridity. We know that the greater the acridity, the greater is the danger to be apprehended from the passage of the urine over the freshly cut surfaces.

According to a tabulated form given by Mr. Hutchinson in the 'Medical Times and Gazette,' of January, 1859, there were in 186 cases, 137 which had not attained the age of 20; and of these 137 there were 123 recoveries; while of 49, which had passed the age of 20, there were found to be 26 deaths.

In the course of our remarks upon the operation we would notice the incontrovertible fact that in the child there is a remarkable immunity from danger, in whom it is performed with a result which yields, as regards success, to none other of the capital operations.

The principal features of difference met with in the performance of it upon the young patient are:—An increased vascularity of the tissues, through which our incisions must pass; the elevation of the bladder to such a degree as to constitute it an abdominal rather than a pelvic viscus, and so to render the perinæum actually deeper. These differences are not, however, by any means unimportant, since the first may occasion some little trouble or uneasiness from the hæmorrhage which may supervene, and the second demands the most careful use of the knife in making the deep incision. The elevation of the point in such a manner as to escape getting into the recto-vesical space, instead of into the bladder,—a mistake most, if not invariably, fatal. As a preventive to this terrible error, we would advise the young surgeon to have the bladder fully distended, so that it might come to occupy a greater portion of the so-called pelvic space, and afford him a not uncertain guide in his manipulations.

We should never lose sight of the circumstance that in the young subject there is a very great readiness to yielding on the part of the structures, and that it is in direct ratio with the youthfulness.

Much of success, however, is dependent upon the skill of the operator, not alone in his mere capacity of surgeon, but likewise as regards his general medical knowledge, whereby he is enabled to adapt at once the means of cure to the symptoms as they present themselves, and so combat them immediately and successfully. Not a little depends upon the judicious selection of cases, since nothing tends more to swell the lists of mortality than operating when the health is undermined, especially if by any organic changes in either the bladder or the kidneys; nothing is more to be deprecated than indiscriminate operation; nothing more reprehensible than to adopt this measure merely as a "*dernier resort.*"

GENERAL CORRESPONDENCE.

ON THE THERAPEUTIC ACTION OF MERCURY.

To the Editor of the Medical Circular.

SIR,—Will you kindly permit me to say a few words in reply to Dr. Thorowgood's letter "On the Therapeutic Action of Mercury," contained in your last number.

It would appear, from a quotation made by Dr. Thorowgood, that Dr. Chambers is one of the most recent writers who have spoken in praise of mercury in inflammatory diseases, and especially in hydrothorax.

I can only say, Sir, that I have the honour to range myself on the other side from that taken by Drs. Chambers, Thorowgood, and other distinguished authorities, but in doing so I only give utterance to the views entertained by a large and increasing number of physicians and surgeons in London, Paris, Dublin, and Edinburgh. Not to go further than your own columns, I may refer to the recent debate upon this subject in the Harveian Society (MEDICAL CIRCULAR, Dec. 2 and Dec. 16), when Dr. Pollock stated that he thought he was only expressing the general opinion of the Profession when he said that he believed that mercury was no longer looked upon as of service in the treatment of internal inflammations, such as pleurisy, pericarditis, or peritonitis, and Dr. Graily Hewitt said that he believed that mercury was never useful in puerperal peritonitis or other puerperal conditions.

With regard to the question of hydrothorax and pleurisy again, in which cases Dr. Thorowgood is so convinced of the advantage of mercury. In the first place, I presume from what I see in his letter, that he administers mercury in such cases, with the theory that it has some power of "hastening destructive metamorphosis," and also of "producing absorption of effused fluids."

Such properties are attributed to it by Dr. Chambers, and appear to be also believed in by Dr. Thorowgood. For my own part, I know of no well-made experiments which tend to prove this theory, and, indeed, I may as well say at once, that I believe, with Dr. Hughes Bennett and others, that mercury has only two undoubted properties—1st, purgative; 2nd, sialagogue. As to the rest of its *virtues*, they remain among the dogmatisms which men believe in without any sufficient evidence, for whenever any disease, such as syphilis, pericarditis, &c., has been treated without mercury, it has been found to be much less troublesome than with it.

Three of the most recent writers on the practice of medicine, Dr. Hughes Bennett, Dr. Gairdner, and Dr. Trousseau have treated at length the question of hydrothorax, and all of them seem completely to have abandoned the practice of administering mercury in that disease. Thus, Dr. Hughes Bennett, in his 'Clinical Medicine,' p. 617, says: "By some calomel is considered to be directly indicated as a means of favouring absorption from the serous cavity, and although I have frequently seen the drug employed for this purpose I have not met with a single instance where its good effect have been unequivocal." Such appears also to be Dr. Gairdner's opinion. As to Dr. Trousseau, as far as I remember, he never once seems to think of such a remedy in pleurisy or hydrothorax. Indeed, in Paris the antiphlogistic properties of mercury are now looked upon as belief

of the past generation, although the drug is still used in syphilis and iritis.

With regard to calomel being useful in peritonitis, is it not a very significant fact that it is not the practice of either Mr. Spencer Wells or Mr. Baker Brown to administer the drug after the operation of ovariotomy. Indeed, I believe the administration of calomel and opium in traumatic cases is now abandoned by the greater part of the best London surgeons.

I am glad to see that Dr. Thorowgood has not much faith in mercury in rheumatic pericarditis. The cases cited by Dr. John Taylor, of University College Hospital, have shown that mercurial salivation often does harm, but never any good in that complaint. Dr. Walshe, in company with Drs. Hughes Bennett, Habershon, and Gairdner, hold the same views with regard to pericarditis.

Lastly, is mercury a cholagogue, or useful in diseases of the liver? I believe that it frequently does much harm in such diseases, and what good it does has seemed to me to be simply owing to its cathartic powers, which it shares with a host of other purgatives. The physiological effects of mercury are actually to *diminish* the secretion of bile (Beale's 'Archives,' vol. i., quoted by Hughes Bennett, 'Lancet,' Dec. 3, 1863), instead of being, as asserted over and over again, a cholagogue.

I have, Sir, attempted, I fear most imperfectly, to answer the views brought forward by Dr. Thorowgood and many others, whose opinions I hold in the greatest respect; and I can only add that my own experience completely corroborates that of Drs. Hughes Bennett, Habershon, Gairdner, Walshe, &c., and I believe that I have more than once seen patients die in pleurisy and other inflammatory diseases, whose vital powers would otherwise have sustained them easily through the disease, had not the (in my opinion) most pernicious influence of calomel been superadded to the disease.

I am, &c.,

CHARLES R. DRYSDALE, M.D.,
M.R.C.P.L., F.R.C.S.E.

Southampton row, W.C.
Jan. 2. 1864.

HOSPITALS AND THEIR MANAGEMENT.

To the Editor of the Medical Circular.

SIR,—Your article on hospitals opens up, I think, a very important subject for discussion, and one in which the whole body of the profession, as well as the public at large, are interested. The question has often occurred to me—is the most made by these institutions of the opportunities afforded for investigating disease?

Have we always the right men connected with them so that ingenuity as well as science be manifested in the treatment and record of cases?

Are the atmospheric changes noted in connection with the changes that occur in various diseases?

Is the effect of diet also noted, and is diet administered with an object in connection with *the* disease, or by a rule laid down?

This subject is, doubtless, studied by many medical men in private practice, but is it made the most of in our public institutions?

Again, are there enough medical men connected with each hospital to prevent hurry, oversight, and fatigue, and to secure the most attention being devoted to the various cases?

Ought not each physician to be limited to a certain number of cases, say fifty out-patients and ten in-patients, by which means the cases would clearly be better studied, and additional workers and observers of disease would be employed.

Should not, also, the cases be somewhat classified? so that the physician, who has made the heart, lungs, liver, or kidney, his especial study, might have such cases immediately under his care and observation.

Clearly there ought to be no monopoly in these institutions. By rights, the utmost good feeling should exist, and not only should the best instruction be secured for the students, but also the best way of communicating it be adopted. Is this the case? and is not Edinburgh far before London in this respect! This is an interesting question for the thoughtful student, as well as for the physician who is excluded from these institutions, excepting as a casual observer.—I am, &c.,

ANTI-MONOPOLY.

MEDICAL THEORIES—THEIR USE.

To the Editor of the Medical Circular.

"It seems to me a most mournful hypothesis, that of quackery giving birth to any faith.—Quackery gives birth to nothing,—gives death to many things.—We shall not see into the true heart of anything if we look merely at the quackeries of it."—CARLYLE on *Heroes.*

SIR,—In a ormer letter I directed attention to some statements of Dr. Corrigan as to all our present theories in medicine being "nonsense." To the error of looking for some *one* great comprehensive law to guide us (as the law of gravitation, the astronomer) in place of such theories, as also to an extraordinary dictum of Sir B. Brodie in 'Fraser's Magazine,' that modern quackeries are giving birth to a very wide faith in them, solely because our young physicians are not adepts at diagnosis.

It is gratifying to find that Dr. Corrigan on the apocryphal nature of his teaching having been pointed out to him, is willing to leave theories and quackeries to the younger men, to be fought out; and that Sir B. Brodie's dictum had such seeds of decay in it that it has only influenced deeply men with homœopathic drug shops. A French *savant* has recently published a very profound essay on the Positive Philosophy of Comte, as applied to modern medicine; the only thing I see he is positive about is that we are in the "gall of bitterness" of direful routine, and men like Dr. Corrigan do not think of or broadly analyse medicine as it is; that our journalism is something like our tinctures and juleps of camphor, a mere decanting of old stale condiments and tinctures from one bottle into another. Even in cases like that of the wretched man, Townley, we as medical men differ more from party bias or rough education in this decanting of our ideas than from that education which *Emollit mores nec sinit, &c.*

I was astonished the other day on going into the chief homœopathic drug shop at the West-end to hear the gentleman behind the counter tell a lady, "Homœopathy progresses, but we have lost our great man,—Sir B. Brodie!" "Ah! those delightful letters in 'Fraser,'" responded the fair heretic, "he was indeed a man before his time; his letters have converted thousands." We have also the slow men who never heard of iridectomy for glaucoma, when the great Sir Astley was consul, or Mr. Abernethy, erewhile a Titan in a frieze coat thundered and made a noise at St. Bartholomew's; I have heard sensible accoucheurs tell their pupils, we had no chloroform when our grandmothers were attended by midwives, and brought forth splendid children" (but we had no vaccination then!) "and as our grandmothers did not want chloroform, surely the women of the present day do not require it." One need not fall out with these slow men, or men after their time, except that their example is most ruinous, and only ruinous in proportion as they are misunderstood by the public and acquiesced in by the Profession.

We have wide room for improvement as regards our young men entering the Profession, but it is not by telling them as Corrigan does, that all theories are nonsense, or as Brodie, that homœopathy spreads from our blank ignorance of what?—Diagnosis. Our "Introductories" of late are what Teufelsdroeck calls "etymological cinders," heaped up year after year on the dull fire of Medical Progress. Our profession ought to be the finest of all the professions, but it is not. We want new pabulum for the fire; there is work for all, but I pity all the young men, for the nuisance of Colleges like rust has so eaten into what ought to be the iron strength of our most noble calling. A large moiety of

the practice of the day is in the hands of a "profanum vulgus" of well-dressed chemists, hydropaths, homœologists, patent quack medicine vendors, "Dr. Sampsons" as vividly and truthfully pictured for all time in the tale of *Very Hard Cash*. Do our Brodies, Joseph Henry Greens, Lawrences, put out their littlest finger to check this? No, verily, but by a policy of "non-intervention" one could easily show that the present sad serious miserable progress of quackery is due to this non-intervention, this *rusticus expectat dum defluit, &c.*

If there be any use of words, the homœopaths are on the same level as the specialists. If we call them "empirics" they see we do not understand the use of words. Nature is their great *vis medicatrix*, over dosing is ours. I think we cannot understand the late Sir B. Brodie's opinions as to diagnosis in the English school, except under this view, that for many years if there was at all a "warp," so to call it in his fine intellect, it was this, that he was inclined to look on all diseases as nervous. All diseases in the main as likely to get well of themselves if left alone. He had seen or heard of (as every man conversant with London hospitals must have seen or heard of) dozens on dozens of knee-joints amputated that proved on examination perfectly healthy, violent inflammation of joints, so called, that ended in hysteria, or neuralgia, or perfect health by doing nothing at all. He had seen that half of our hospital therapeutics was a farce and "out door" hospital or dispensary prescribing a cruelty and a delusion. That pneumonia and typhus, if left to themselves, and the system supported by wine will recover better than by the bleedings of former years, that the lancet, in a word, is an anachronism for ever more. The only school in London on which the lamented baronet has left any impression is St. Bartholomew's, and the followers of Mr. Skey's practice will recognise what I say. Sir Benjamin had not examined much into Hahuemannism, and so he said our bad diagnosis was the only and chief cause of its spread.

In a previous letter I explained that our theories are like scaffoldings, but we must not mistake them for the building.

Do we sometimes allow theory to mislead us? the wish scientific is it ever father to the thought? Thus in such an obvious thing as the use of wine in fever or pneumonia, the blood seen at surgical operations under chloroform, which is scarlet, *if respiration be not embarrassed*, venous or black, if it be embarrassed; it has taken us many years to arrive at these two facts, one set of theorists holding strongly that they had always seen black blood as a rule, showing that anæsthesia is only another word for asphyxia or suffocation, other surgeons like the knights of old (only seeing the opposite side of the shield) always had seen scarlet blood, the logical effect in reality of the chloroform being *nil*! Overdosing by illegitimate practitioners, chemists, and others is the rock on which the Profession is going shipwreck. Also have we all sorts of errors in our hasty generalisation or grand laws without the picturesque grace of Sir Kenelm Digby, or Cervantes, to make us love or like them. Cervantes was a very early Hahnemannite, for he soberly prescribes for a gipsy who was bit by a dog, as a cure of hydrophobia, some of the hair of the dog that bit the patient mixed with rosemary, to the wound. J. Stuart Mill says all religious superstitions are inductions! Homœopathy is a superstition.

I believe the mere arithmetical system or "statistics," so called, is very liable to give us but half truths, or hasty generalisations or naked facts worth very little, as we can reason them away. Modern deductive logic argues from the known to the unknown, but by comparing groups of facts, and honestly taking in those reasons as most essential. The Chinese are not bad, they say, for if we have the facts the induction is only a toy! Macauley, Mill, and Liebig, think almost the same.

We have also men often arguing about different nay opposite things, thinking round about in an erroneous generalisation such discordant things are all the same thing, *i.e.*, it is quite the fashion, but it is not pathology, to rank half-a-dozen different things under the name cancer, to doubt as to what is secondary cancer, and because cancer cells are not found in the blood, (as we never look for them there) therefore secondary cancer must be a mistake. Now cancer elements have been found in the blood, and secondary cancer, in the glands of the axilla, to wit, in hard scirrhus, is not found always, but is found always when the cancer softens. Again, we may have so called cancer cells in a growth which is not malignant, and a growth unfortunately malignant in which are no cancer cells, but the empiricism of Velpeau is superior to all our grand generalisations so roundabout.

The Indian Army is being decimated by tubercular diseases, Miss Nightingale says, and the great leading newspaper asks in dismay, Can any body tell us what is tubercle or what is its origin? We have a theory as to bad ventilation here that might help us, but Corrigan says all theories are rank nonsense!

One of our chief officers of health, and editor of the leading Medical journal, cites Dr. Jenner's generalisations in fever as the greatest triumph of late years of the inductive philosophy, but Dr. Stokes and Dr. Kennedy, of Dublin, never cease their objections to these generalisations, and believe typhus, typhoid, relapsing fever, &c,, all one and the same, the poison one and the same. Dr. Christison, too, now comes to upset Dr. Murchison's doctrines of a like kind. We evidently want a great deal of calm extended observation in this class of diseases. We do not say that small-pox in a patient previously badly vaccinated, if very mild, is a different disease and subject to different generalisations, from primitive small-pox.

Again, let us look at the generalisations on the syphilitic diseases, and mercury, the great disturbing cause. Ricord changing his dogmas as often as common sense comes to correct pedantry; the two most unmeaning books I know are Bacon's and Hahnemann's rhapsodies termed *Organon*, yet how they are quoted as to fevers, cancers, blood coagulation, &c.

There is another peculiar line of reasoning now-a-days very common. Mr. Lister's on the 'Coagulation of the Blood' is eminently the last instance. Virchow and others do not believe in the Ammonia theory at all, so Mr. Lister labours to prove that blood coagulates, not because of ammonia or vitality lost, but it coagulates (according to the severest application of the inductive philosophy, in a logical circle rather), it coagulates; well, because it coagulates or has acquired a tendency to coagulate, that's all! To do Mr. Lister but justice, he does not wrap up all this in grandiose words, the law of coagulation, "it coagulates because it coagulates," but this is the whole thing. The 'Lancet' receives it as Mussulmen do the 'Koran,' it is a miracle!

Then we have very eminent men who tell us vivisections have never added a single fact to physiology; that Harvey's splendid induction of the course of the blood from the direction of the valves of the veins, as the first fruits of the *Novum Organon*, is the true way to add facts to physiology, but such foolish men do not know that the *Novum Organon* was not written till long after Harvey's discovery.

Finally, I would with all submission say, if we are to adhere to the proper use of words, a theory is the "bright consummate flower" of many roots of knowledge stuck in the otherwise sterile soil of every-day practice. What do we know of the blood without its theory of the circulation? what of inflammation but from Wharton Jones's theory &c.? what of a dozen other things, but from their theory. Again, hypothesis is said to be a system formed under some principle not proved, but there are principles that prove themselves. You cannot prove sugar is sweet, or vinegar sour, they prove themselves, and on this quibble mountains of medical arguments have been raised. It may be said too that globules and high dilutions cure where our frightful overdosing of general practitioners fail, but there can be no greater mistake than to say this is due to bad diagnosis of disease by our young physicians and surgeons. Nature cures while we are squabbling.

P.S.—Dr. Whewell believes "*false* theory often proves more advantageous to Science than the absence of theory." Truth in a word energizes or makes itself felt sooner out of error than out of confusion. It is to be feared the

"coagulation of the blood," absence of theory, or fashionable negative moonshine about "secondary cancer," or glaucoma and iridectomy, or the latest negative that frost is the cause of change of type in disease! may have given some colouring to Dr. Corrigan's extraordinary statements; but at least out of such confusion let us guide our younger students. Specialities differ from quackeries only in this,—that the latter partake of the nature of trade, they give birth to nothing; give us any false theory in their stead, we shall judge it sooner by its opposite than the fogs and roundabouts of one-sided journalism!

I am, &c., CHARLES KIDD, M.D.

Sackville street, Dec. 31.

REVIEW OF BOOKS.

Notice on the Law of the Production of Sexes in Plants, Animals, and Men. By Marc Thury, Professor of the Academy of Geneva. 1863.

M. Thury, commencing with the vegetable kingdom, shows that the stamens and pistils of plants, or the male and female organs, are merely variations of one common type, and from the experiments made by Knight upon water-melons and cucumbers, it appears that a more complete maturation of the vegetable juices brings about a development of male flowers in preference to females. Passing on to animals, it was found by Huber that in bees an early fecundation produces females, and a later one always produces males. M. Thury has some reason to believe that in poultry the cocks of the brood are from the last laid eggs. M. Thury had the opportunity of proceeding with his experiments on the mammalia in a large farm especially devoted to the breeding of the bovine race. In the rut of the mammalia, the ova are loosened from the ovary at the commencement of the period, and they are in a condition to be fecundated as long as the period of heat lasts. Now it was found experimentally that if the cows were served at the beginning of the rut, the offspring would be females, and if at the end, when the maturation of the ova would, of course, be more complete, they would be males; and the gentleman, on whose farm these experiments were performed, testifies to the uniformity of the results obtained.

It is suggested, rather than explained, that the same law prevails in the human subject, but this part of the matter is somewhat obscure.

If M. Thury's experiments should be found successful in other instances, a very important discovery will have been made in physiology, and the economical results are obvious. M. Thury is a scientific as well as a practical man, and the subject which he has broached in this small pamphlet is worthy of the deepest attention.

The Second Step in Chemistry: or the Student's Guide to the Higher Branches of the Science. By Robert Galloway, F.C.S., Professor of Practical Chemistry, Museum of Irish Industry. With illustrations on wood, pp. 771. London: Churchill and Sons, 1864.

The First Step in Chemistry is comparatively an easy matter. The student must make himself acquainted with the names and properties of some sixty elementary bodies, not half of which are of essential interest to himself or any one else. He must learn the method of preparing gases, of reducing metals, and of applying tests, and he must commit to memory the names, the atomic numbers, and other leading characters of the chief substances mentioned in chemical books and lectures. This part of the study is full of fascination by the brilliancy and variety of many of the results obtained, and by the facility with which the experimental processes are performed.

Mr. Galloway has already guided the student in this his first step, in a very able work which has attained a third edition, and he now leads him on to the investigation of the deeper mysteries of the science. It is absolutely indispensable that the chemical aspirant should master the contents of the first book before he attempts to unravel the intricacies of the second, but if he has diligently learned the preliminary matters to which we have alluded, the transition to the more difficult ones will be as easy as the progress of the schoolboy from common arithmetic to the operations of algebra. Having acquired an intimate knowledge of the characters of the chief elementary bodies, and of their mutual relations to one another, he will be prepared to enter upon the transcendental parts of chemistry, such as the calculation of specific gravities, the relations of volumes and atomic weights, the theory of the formation of salts, the laws of isomorphism and isomerism, the phenomena of dialysis and of the diffusion of gases, the nature of the organic radicals, the processes of fermentation, and many other kindred subjects requiring a combination of practical experience with powers of generalisation and the habit of close reasoning.

These are the subjects, together with many others of a like nature, which form the materials of Mr. Galloway's present volume, which displays immense research, and the contents of which are arranged in a very logical manner. Mr. Galloway shows himself a complete master of his subject; and the book, with its numerous and complicated formulæ, and its neatly-executed wood-cuts, is got up in the finished style which characterises the works published by the Messrs. Churchill.

LEGAL INTELLIGENCE.

PERILOUS ATTACK BY AN ALLEGED LUNATIC.—Mr. Pearse, of 1 Avery Farm row, Pimlico, accompanied by his two sisters, applied to the magistrate for his advice under the following circumstances:—

It appeared from their representations that on Thursday night a juvenile party was given at the house of Mrs. Bourne, of 6 Moore street, Chelsea, at which Mrs. Lovesey and Mr. Sidney Edward Pearse, who are the sister and brother of Mrs. Bourne, were present, as also Mrs. Pearse, of 1 Avery row, Mr. Sydney Pearse's sister-in-law. As the party were about leaving, Mr. Sydney Pearse struck his sister-in-law, Mrs. Elizabeth Mary Ann Pearse, a blow over the shoulder, and she staggered towards the fire-place, exclaiming, "Thank God, it has missed my heart," at which time she plucked part of a broken dagger from her left breast, which was followed by an issue of blood, and the point of the dagger had fortunately struck against the breast bone, by which circumstance her life was probably saved. After this Mr. Sidney Edward Pearse was lost sight of, but next found at the top of the house, where he had made a desperate attempt to commit suicide. Two medical gentlemen had seen him, and there was no doubt he was deranged; but in consequence of actions recently brought against medical gentlemen for the expression of their opinion on such matters they were unwilling to give certificates, and the friends entreated the assistance of the magistrate to restrain Mr. Sidney Pearse from committing further violence upon himself or others.

Mr. Selfe immediately granted a summons for Mr. Sidney Edward Pearse's apprehension, which was forthwith executed, and the accused was placed before the magistrate.

Mrs. Emma Louisa Lovesey said that prisoner lived at No. 6 Moore street, in his sister's house. At about half-past ten on Thursday night he came behind Mrs. Elizabeth Mary Ann Pearse, his brother's wife, and took her round the neck and she immediately left him. Subsequently she was found wounded as above described, and had been confined to her bed ever since. Prisoner had been drinking.

Mrs. Bourne was called, and said there had been no quarrel between the parties before the dangerous occurrence spoken of. Prisoner was suffering under a delusion that she and a man were following him about to murder him. On the same night shortly after the transaction witness heard fearful groans, and on searching the house found that he had gone on the roof where he was discovered, with his throat cut in two places and bearing five wounds on his breast. Dr. Whitmore attended him and pronounced him insane.

Prisoner was remanded for a week.

TO OUR SUBSCRIBERS.

Since 1861 *the Subscription to this Journal has been* 19*s.* 6*d. per annum, if paid in advance, and* 21*s.* 8*d. credit.*

In consequence of the many improvements introduced into the New Series, with others in contemplation, involving considerable outlay, placing the Journal quite on a par with its contemporaries, the subscription henceforth will be 21*s.* 8*d. if paid in advance, or* 26*s. credit.* 6*d. per Number stamped,* 5*d. unstamped. Or the Journal can be procured through any Bookseller or Newsman in the usual course of trade.*

THE MEDICAL CIRCULAR.

THE SIGNING OF LUNACY CERTIFICATES BY MEDICAL MEN.

A case brought before Mr. Selfe, the Magistrate of the Westminster Police Court, on Monday week, most painfully illustrates the jeopardy in which the lives of the public are at present placed in consequence of some actions lately brought against Medical men for performing what they conceived to be their duty in restraining the violence of persons alleged to be in a state of insanity, and dangerous to themselves or others. We have copied the newspaper report of the case to which we allude, in another part of our Journal, and we think it so important that we make no excuse for offering a few remarks in reference to the facts themselves, and to the inferences which may be naturally deduced from them.

We are told that at a juvenile party, a gentleman aimed a blow with a dagger at a lady relative, who immediately staggered, and found that she was wounded. On examination, a portion of the broken weapon was found in her breast, and on its withdrawal, a considerable quantity of blood flowed from the puncture. The point of the dagger had struck against the breastbone, by which, the Report goes on to state, the lady's life was probably saved. After this occurrence, the perpetrator of the deed was missed for some time, but was eventually found at the top of the house, where he had made a desperate attempt to commit suicide. Two Medical men had seen him, and, we are told, there was no doubt he was deranged, but in "consequence of actions recently brought against Medical men," we quote the exact words of the 'Times' report "for the expression of their opinions on such matters, they were unwilling to give certificates, and the friends entreated the assistance of the magistrate to restrain the alleged lunatic from committing further violence on himself or others." Mr. Selfe immediately granted a warrant for the apprehension of the accused person, who was accordingly brought up in custody, and appeared perfectly calm and collected. The wounded lady had been confined to bed ever since the event, which occurred on the previous Thursday.

The above report appears in all the newspapers, and we may assume it to be substantially correct. It shows that Medical men now shrink from the duty of either expressing an opinion upon such cases, or of taking such measures as may prevent the perpetration of violence and outrage by alleged lunatics. No one surely can blame them for acting with such caution, under the heavy responsibilities which any action done by them, or any opinion expressed by them in such cases, may entail on their character or their finances.

It is quite evident, as matters now stand, that in whatever manner a Medical practitioner may act, he incurs very great danger, from which the law offers him no protection. If he finds a person in a state of raving delirium, and doing mischief to himself or others, and he forthwith recommends the imposition of restraint, he is clearly liable to an action at law as soon as the patient recovers, because he has invaded the liberty of the subject, and taken the law into his own hands. It will be recollected in the case of Symm v. Fraser and Andrews, that the defence successfully set up, was that the defendants imposed no restraint, and did not recommend it, and that, in fact, the restraint was imposed by the patient's own friends. In another case which occurred some year or two ago, an action was brought against Mr. Wakem for imposing restraint, or authorising its imposition, upon a person said to be suffering from *delirium tremens*, and a verdict was given against him, although only for a nominal sum, on the ground that he ought not to have restrained the plaintiff unless under the authority of a certificate of lunacy. The law upon this point, therefore, is clear enough, namely, that an alleged lunatic cannot be controlled in any way unless by the means pointed out by the Acts of Parliament.

Now these means consist in the filling up of a Certificate of Lunacy, which is so framed as to prevent all undue influences, so far as human intelligence can foresee. The Legislature has thought proper, in the case of private patients, in order to avoid the public exhibition of the alleged lunatic before the magistrate at a police court to entrust the duty to the immediate relatives of the patient, fortified by the opinions of two Medical men, who must see the person separately, and who must not in any way be in partnership with one another. The filling up of the Certificate by the Medical men is nothing more than the expression of an opinion on their parts, and it is exceedingly difficult to understand why they should be responsible at law for such opinion any more than for stating their opinion that such and such a one is the subject of Typhus Fever, or Consumption, or Dropsy. It has been shown, however, that the expression of such an opinion although not a crime or a misdemeanour, and though made in perfectly good faith, may render a Medical man liable to heavy pecuniary damages, and we cannot wonder, therefore, that the Profession declines the responsibility of giving it, with such a probable result in view.

It is very likely that recent events will introduce a thorough change in the system of filling up Certificates of Lunacy. The Profession will only be too glad to be relieved of the duty which is at present laid upon them, and they will readily transfer the obligation into the hands of others. They have hitherto believed that they were acting only in the interests of humanity in preventing murder, or suicide, or other kinds of violence; but they will discontinue these services when they find they are no longer needed. There are of course some practical difficulties in the way of altering the present law; but it should be generally understood that Medical men are not *compelled* to sign Certificates of Lunacy. Their doing so is a voluntary act on their part, and they have considered it as a portion, and a very disagreeable portion, of their duties, performed for the protection of the public.

It is now time to protect, not the alleged lunatic, but the Medical Profession. The sensation writers of the day are either not aware, or they are wilfully blind to the fact, that abundance of penal enactments exist to protect lunatics, or alleged lunatics, from their own relatives, from Medical men, and from the keepers of lunatic asylums. It is just possible that Medical men may not be the best judges of what does and what does not constitute insanity, and that this *kind* of knowledge is better understood by the editors of newspapers, the writers of sensation novels, and police-magistrates. If such be the case, in Heaven's name, let these persons perform the necessary duties, and undertake the responsibilities; all that the Medical Profession wish is that the lives of the public and of individuals should be protected from violence and wrong, and if this object be attained, it matters nothing whatever to whom the duty is confided.

IRIDECTOMY.

The subject of iridectomy has of late occupied, as it well deserves, a large share of the attention of the Medical Profession. It is a new operation, strongly recommended in some quarters for the relief of a disease, the pathology of which has usually been obscure, and the treatment of which has usually been unsuccessful. Many Medical men are still in doubt as to the nature of glaucoma, the disease in which iridectomy is now generally practised, and as to the reasons why this particular operation should be adopted for its relief. One of our contemporaries, the 'British Medical Journal,' has devoted considerable space to the elucidation of these points, while expressing itself as being sceptical as to the measure of relief afforded by the new operation; while some others, as the 'Medical Times and Gazette,' appear to treat almost as fools all those who entertain any doubts upon the matter, and hold up the operation to general admiration as one of the triumphs of Ophthalmic Surgery. We must confess that with every respect to the authority of Gräfe, who first advocated the operation for the cure of glaucoma, and to those distinguished ophthalmologists in our own country who have followed in his steps, we must at present rank ourselves on the side of the sceptics; but we are quite ready to be convinced as soon as sufficient evidence is placed before us.

We must first ask what is Iridectomy? and what is Glaucoma? In its etymological meaning iridectomy signifies the cutting out of the iris, either wholly or partially, and it is plain to every one that such an operation will be manifestly useful when the object is to form an artificial pupil in consequence of inflammation or injury to the iris, causing mechanical obstruction to the passage of the rays of light. But how is cutting out a portion of the iris useful in glaucoma? and what is glaucoma?

Upon this point pathologists are not yet agreed. The word has hitherto been applied to a condition of the eye somewhat resembling amaurosis, but distinguished from it by the greenish appearance of the background of the eye, and resembling it in its serious and often incurable character. But of late years attempts have been made to define more accurately the morbid conditions constituting glaucoma, although its pathogenesis is restricted by Gräfe to a choroiditis in the early stage, the pathology of the latter stages being left uncertain by the German ophthalmologist. Now, admitting that glaucoma is at first an inflammation of the choroid membrane, how does an excision of part of the iris relieve that malady?

We have read with considerable interest a letter published in one of our contemporaries, from the pen of Mr. Haynes Walton, who has given a history of the operation itself, and of the disease which it is intended to relieve. It seems that Gräfe's attention was first drawn to the efficacy of this treatment in internal inflammation of the eye-ball by observing the results of the operation for artificial pupil by excision, after irido-choroiditis with closed pupil. He then proceeded to employ the operation in glaucoma, which he regarded in its early stage as an inflammation of the choroid. Mr. Haynes Walton asserts that any benefit obtained from iridectomy in this latter disease is derived, not from any direct effect on the iris, but solely in consequence of the evacuation of the aqueous humour. The operation, therefore, might as well be Keratotomia or Keratonyxis, the object being merely to make an incision into the cornea for the purpose of allowing the escape of the aqueous humour, and the iris need not be incised at all. The effect of this proceeding seems to be to relieve tension, and in this effect consists its utility. Such, at least, is Mr. Walton's explanation.

It appears that the idea of tapping the cornea to relieve congestion or inflammation of the eye really originated with the venerable Dr. Wardrop more than half a century ago, when he published a paper "On the Effect of Evacuating the Aqueous Humour in Inflammation of the Eyes," in the Medico-Chirurgical Transactions. In this paper he remarks that the great and immediate relief afforded by the evacuation of the aqueous humour arises chiefly from the sudden removal of tension. He wishes it to be understood most probably that the discharge of the aqueous humour is not to be recommended as the sole remedy in any case of ophthalmia, but it is only to be considered as

a powerful auxiliary in some cases, and a sure and only one in others, of preventing the total destruction of the eye.

Such are some of the facts and opinions advanced by Mr. Haynes Walton, who has evidently paid much attention to the subject. Mr. Bowman, however, strongly advocates the operation as recommended by Gräfe, and asserts its utility independently of the relief of tension, which he does not regard as an essential condition of the numerous lesions comprehended under the name of glaucoma. We are much inclined to think that Mr. Haynes Walton's views are, at all events, deserving of deep attention.

SUMMARY OF THE WEEK.

THE ACCOUCHEMENT OF THE PRINCESS OF WALES.

This happy event, which occurred on Friday evening last, took the country by surprise. The Princess of Wales was amusing herself on the ice at Virginia Water until four o'clock in the afternoon, and at two minutes to nine in the evening the infant Prince was born. Without pretending to the accuracy of information on this interesting and delicate subject, which appears to be possessed by our contemporary the 'Observer,' we believe that the birth of the infant was not expected for about two months, and the actual result was that preparations had not yet been made for his reception. No nurse was in attendance; Dr. Farre, who had been engaged to attend on the occasion, was at a distance; Dr. Sieveking, who is not the physician-accoucheur, but the physician in ordinary, arrived when the business was over, and the actual medical ministrations were afforded by Dr. Henry Brown, a general practitioner at Windsor, who is the local Surgeon to the Royal Family, and who thus had the sole and undivided honour of attending on the auspicious occasion.

THE NEW PRESIDENT OF THE MEDICAL COUNCIL.

Since the publication of our last Number, we have learned with regret that the objections which we stated to exist in the mind of Dr. Watson, as to his acceptance of the office of President of the Medical Council, have been so strong as to induce him definitively to decline the proffered honour. We understand that Dr. Burrows will, in all probability, be proposed and elected, and on the principle that if we cannot have what we like, we must like what we have, we congratulate Dr. Burrows on the prospect of his appointment. The only objections that can be urged against this gentleman are his comparative youth, his want of weight and influence, and the consequent fear that he will be unequal to the task of controlling the somewhat unruly elements of which the Medical Council is composed. But he is a gentleman and a scholar, and as his two predecessors have been surgeons, it is only fair that a physician should in turn preside at the Council.

THE RESPITE OF GEORGE VICTOR TOWNLEY.

The public excitement caused by the respite of this convict, has by no means diminished since his removal to Bethlehem, and the newspapers, perhaps for the want of something better to write upon, are still full of complaints and remonstrances against Sir George Grey for the course he has adopted. In many of the observations made by our non-medical contemporaries we entirely agree, and more especially in their insinuations that there is one law for the rich and another for the poor. We stated last week our impression that if Townley had been a poor man, he would inevitably have been hanged, and that money, and the services of Dr. Forbes Winslow, had saved him from that catastrophe. We should have been, however, more satisfied of the sincerity of the opinions expressed by our contemporaries, if we had found that they themselves dealt out equal justice to the rich and the poor. Last year we argued that the poor unfortunate lunatics, Fooks, Burton, and Holden, ought at least to have been allowed the benefit of the advice of experts, to assist the judges, juries, and the Government, in arriving at a just decision in their cases; but none of the non-medical papers even entertained the suggestion, and the poor wretches were hanged in due course. The great objection urged against the respite of Townley is the irresponsibility of the agency by which the respite has been effected, and it is argued that the reasons which have induced the Government to spare the convict's life ought to be made public; and it has been suggested that another Commission should be appointed, consisting, not of Commissioners in Lunacy, or of Medical men engaged in Lunacy practice, but of independent men, capable of forming a calm and unbiassed judgment. To this course there cannot be any valid objection; but under all circumstances we hope that on any subsequent occasion, where questions similar to the present may arise, equal justice will be dealt out to the rich and the poor, and the latter, as well as the former, will be allowed the assistance of the Lunacy Commissioners to decide as to their sanity or insanity, or at any rate to assist the judge and jury in arriving at a just conclusion.

THE CASE OF SYMM V. FRASER AND ANDREWS.

We are happy to state that the subscription instituted for defraying the expenses incurred by the defendants in this iniquitous trial is proceeding very favourably, but we quite agree with the writers of some letters in the pages of one or two of our contemporaries, urging the necessity of the contributions being general, and not confined to a few public-spirited persons. As matters stand, we find that a limited number of the members of our Profession come forward, on repeated occasions, to succour their brethren when overtaken by unmerited persecution, while the great majority refrain from offering any succour at all. When the disinclination to subscribe on such occasions arises from inadequate means, we should not utter a word of comment, far less of censure, for we know but too well how many of our body are struggling for bare subsistence under privations which are not the less severe, because they are borne in silence. But we cannot too strongly express our surprise that the names of many of our Profession, who are known to be living in affluence, are often conspicuously absent when such sympathy is expected. We feel that the hint now given is sufficient for the present time; but we would

emphatically impress upon all ranks of the Profession the necessity of instituting some common fund for the defence of gentlemen dragged into Courts of Law for matters connected with the exercise of their calling. We understand that Mr. Brady, M.P., who has proved himself a staunch friend to the Medical Profession, and who, as is well known, is one of our own body, has expressed himself very warmly in favour of such a movement, and we hope that his praiseworthy efforts will be seconded as they deserve to be. In the case of Drs. Fraser and Andrews, the Medical witnesses called for the plaintiff indignantly deny that they instigated the action in any way, and one of them (Mr. Barrett) distinctly declares that he advised Mrs. Symm not to bring it. In the name of common sense then who *did* advise her to adopt such ruinous proceedings? We feel that the whole affair still requires explanation in justice to the plaintiff as well as to the defendants, and we must repeat our suspicions that there are some villains in the back-ground in this affair who have not yet been detected.

MEDICAL EDUCATIONAL REFORM AT EDINBURGH.

The *Magnus Apollo* of the Edinburgh University, Mr. Syme, has uttered his oracular sentiments on the subject of Medical education and examination, and it is only right that the small fry of the Profession, scattered throughout the rest of the world, should listen to the utterances. For our own part we think that Mr. Syme's opinions on these subjects are offered in singularly bad taste, because as a Professor in a University distinguished for the scientific men whom it has sent forth into the world, his aim ought to be to encourage variety as well as profundity of learning, rather than to restrict its scope within the narrowest limits compatible with the exercise of a Profession. We intend, on an early occasion, to expose the shallowness as well as the incorrectness, of Mr. Syme's views, but at the present time, we merely allude to them to express our dissent from the sentiments they embody and the plans of supposed improvement which they suggest.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. SKEY continues his clinical observations entitled, "Records of Cases Treated in St. Bartholomew's Hospital." The cases are, as before, of a miscellaneous character. Fractures of the thigh were nearly all treated with the long splint, but in two cases, complicated with injuries to the head, united with loss of length of the limb, Mr. Skey refractured the femur, the results in both being the restoration of the original length of the limb and complete recovery. Fractures of the leg were treated by Mr. Skey, almost without exception, with the pillow instead of splints. In some cases of Pelvic Abscess, attended with constitutional debility, the treatment consisted in the adoption of a pure tonic regimen, and the operation of incision when the suppuration was complete. The treatment of Hysteria, or local nervous disease in women, deserves great attention, because mistakes have often been made by confounding such affections with inflammation and other serious maladies. Mr. Skey particularly alludes to those hysterical forms of spinal disease, which were formerly mistaken for caries or necrosis of the vertebræ, and were improperly treated by mechanical appliances, or under confinement to a recumbent posture, whereas constitutional remedies, exercise, and good diet, would have effected a speedy cure. Mr. Skey also describes a case of a young lady, subject to inversion of the right foot, who was treated unsuccessfully by orthopædic appliances, but who recovered suddenly under the use of wine, valerian, and ammonia. In a case of Chronic Enlargement of the Right Testicle, in which the malignity or non-malignity of the disease was a matter of doubt, Mr. Skey cut down on the spermatic cord, and tied the spermatic artery. The result was that the testicle came away, eventually, in a sloughy state, and the man left the hospital apparently recovered. Mr. W. S. SAVORY continues his "Observations on Caries and its Relations to Necrosis," showing that these two affections are closely allied together, necrosis being usually the result of acute, and caries of chronic inflammation. In necrosis the death of the bone is sudden, in caries it is gradual, but simple necrosis is extremely rare, for it is usually associated with caries. Dr. J. R. WARDELL gives a "Report of a Case of Poisoning by Burnett's Disinfecting Fluid," which occurred in May of last year, and which was published at the time. The case was that of a lady at Tunbridge Wells, who took the poison in mistake for Dinneford's fluid magnesia, and died in spite of the treatment adopted. Dr. Wardell refers to two other cases of poisoning by the same liquid, both being fatal. The action of this poison is so rapid that treatment is generally unavailing, but the best remedies appear to be alkaline demulcents, white of eggs, and opiates. Dr. JAMES PALFREY communicates a "Report of a Case of Twin Labour in which Uterine Action commenced and progressed to the Second Stage during sleep." The lady who was the subject of the case, was confined of twins, a month before the expected period; the children being born very rapidly as soon as she awoke from a sleep of four hours' duration. The interesting point in this case seems to be that uterine action commenced, and labour advanced to the second stage, during the sleep of the patient. Dr. Palfrey has been unable to find a similar case recorded in the books on obstetric medicine or medical jurisprudence, or in the notes made in the practice of his father in-law, the late Dr. Lever: but he thinks that the instance now recorded settles the point as to whether efficient action of the impregnated uterus can or cannot take place during natural sleep.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. SIMPSON, of Edinburgh, continues his Clinical Lectures on the "Diseases of Women," but his present subject is the arrest of hæmorrhage by the process of Acupressure, which we described in our last number, and which consists in passing a needle under the end of a divided artery, and pressing the vessel against the soft parts. The process is applicable to large as well as small arteries, and the time required to keep the needles in their place varies according

to the size of the artery pressed upon, the largest arteries divided having been found closed within fifty hours, and a less time being required for the smaller arteries. Dr. Simpson relates the particulars of six cases of surgical operations in which Acupressure was successfully adopted, and he then proceeds to explain the local conditions necessary for the primary union of wounds. These conditions are chiefly the accurate adjustment of the flaps, and the removal of every portion of foreign body from the wound, so as to insure what is called healing by the first intention. In answer to the question whether Acupressure is not more difficult than the deligation of arteries, Dr. Simpson states that it is not, and he adduces several instances to prove that this new process is both easy and safe in its practical application. Dr. GEORGE HARLEY, of University College, continues his course of Lectures on the "Urine and Diseases of the Urinary Organs," and having concluded his introductory remarks on urine in general, he now describes the physical and chemical characters of human urine, as to its smell, taste, and reactions. The acidity of normal urine depends on the united presence of acid phosphate of soda, uric, hippuric, and lactic acids. The hydrochloric and sulphuric acids, although present in normal urine, do not contribute to its acidity, for they are both combined with bases in the form of neutral salts. Mr. JOHN WOOD, of King's College, communicates a paper "On Rupture," but it contains only a general sketch of this affection, describing the different parts of the body where a hernia may occur, and the constitutional peculiarities of the persons who may suffer from it, together with some anatomical features observed in the inguinal hernia. Dr. HANDFIELD JONES continues his "Records of a Case of Proptosis, Goître, Palpitation, &c.," with remarks. The case itself, which was one of what is called Exophthalmic Goître, was described last week, and Dr. Jones now explains its pathology and treatment. He regards the affection as consisting mainly in a relaxed and irritable condition of the nervous system, but distinct from hysteria, and to which Dr. Jones would apply the term *neurolysis*. The urine, during the height of the disorder, was of a deep red colour, indicating a considerable destruction of the red globules of the blood. In treating the case, nitrate of silver was useful, apparently by diminishing the irritability of the stomach; opium was efficacious by its sedative influence; strychnine appeared to raise the general tone of the system; and country air produced remarkably beneficial effects. Dr. PEACOCK continues his "Cases of Unusual Slowness of Pulse," with remarks; and he associates this condition in some instances with disease of the heart. The relation of cause and effect, however, is not very manifest, for in one of the cases recorded, the result was not fatal, and in another the patient died, but no post-mortem examination took place. Although, too, Dr. Stokes and Dr. Quain have pointed out that shortness of pulse frequently accompanies fatty degeneration of the walls of the heart, such is by no means invariably the case, and, indeed, this kind of pulse is only exceptional in cases of fatty degeneration, the most usual character being weakness and irregularity. It is by no means unusual for the pulse to fall below the natural rate in convalescence from acute febrile diseases, especially from severe uncomplicated typhus.

THE 'GLASGOW MEDICAL JOURNAL.' No. XLIV. JANUARY, 1864.

The first article in this number is entitled "Experience and Treatment of Diphtheria in Campbelton and Neighbourhood," by Dr. WILLIAM GIBSON, who has since August, 1860, observed and attended several cases of the disease. Dr. Gibson's remarks are of a very practical character, but do not exhibit much acquaintance with the literature of this very strange disease, and another drawback to the value of the paper is the absence of post-mortem examinations, the prejudices of the Scotch population being arrayed against this method of investigation. In only one case was a post-mortem examination allowed, but it may be remarked that the mortality was by no means so considerable as has been described in other localities; for out of fifty-one cases, only fourteen died. From this circumstance, from the absence of autopsies, and from the rather aberrant character of some of the symptoms described, we are inclined to doubt whether all the cases were instances of true diphtheria, although many were undoubtedly such. Dr. Gibson draws very fairly the distinctive characters separating diphtheria from scarlatina, but he is hardly equally successful in separating tracheal diphtheria from croup, which are considered by modern French pathologists as the same disease. The cases of diphtheria treated by Dr. Gibson were not of a contagious character, and the outbreak of the disease appeared to be independent of locality, water-supply, or unfavourable hygienic conditions. The best local treatment was the application of hydrochloric acid to the throat, and the general treatment was alterative and mildly stimulant. Tracheotomy was performed in one or two cases, but not with any marked success. The second paper, on "Certain Abuses of Caustics," is by Dr. JAMES MORTON, and unlike the first paper, it displays a very considerable knowledge of the literature of the subjects discussed, but is not illustrated by any practical details. Dr. Morton's object is to show that, although caustics are valuable agents when used in moderation, their injudicious employment often does great mischief. The chief diseases to which Dr. Morton refers as illustrating the bad effects of excessive cauterisation are diphtheria, and the allied affections of the throat, and syphilis. The application of strong caustics to the cervix uteri is briefly alluded to, and the injurious results often following this treatment are pointed out. The conclusions at which the author arrives are that the value of cauterisation in many diseases is overrated, and that the whole subject deserves reconsideration at the hands of the Profession. Dr. GEORGE BUCHANAN, of the Glasgow Royal Infirmary, relates a series of "Cases of Tracheotomy in Croup and Diphtheria," in continuation of those already published by him in the July number of the Journal. This paper is entirely practical, and the results seem to prove that the operation might be more generally

successful if it were adopted at an earlier period than is usually the case. In Dr. Buchanan's experience he has performed the operation fifteen times, and in five instances the result was successful, and he thinks it certain that the lives of the five patients were saved by the operation. Dr. A. L. KELLY relates "Two Cases of Inversio Uteri, with Remarks." In one case the accident was caused by an attendant suddenly pressing her closed fist into the abdomen before the child was born; in the second, by a midwife pulling the cord in retained placenta. In both cases the uterus was replaced, and the patients recovered. Mr. HOLT relates a "Case of Death from Placenta Prævia," the woman having died before any Medical assistance could be obtained, and the result being apparently due to the sudden shock to the system from loss of blood. Dr. LEISHMAN concludes his paper on the "Mechanism of Parturition." He avows himself an opponent to the practice of supporting the perinæum in labour, as he considers it to be useless in any case, and often injurious. The greater part of the paper is devoted to a consideration of the position of the cranium in labour, and the different classifications of these positions by British and foreign obstetricians are described and commented upon at great length and with singular learning and ability.

'THE SOCIAL SCIENCE REVIEW.' No. I. NEW SERIES, JANUARY 1, 1864. Edited by BENJAMIN W. RICHARDSON, M.A., M.D.

This excellent periodical, which has hitherto been published every week, now appears in the form of a Monthly Journal. It has peculiar claims to the notice of the Medical Profession, as it is edited by a physician of acknowledged eminence, and devotes a considerable amount of space to the discussion of Medical topics. The idea of popularising medicine, and placing its professors in a true light before the general public, is one that ought to receive powerful support, more especially at the present moment, when, by some unaccountable turn of caprice, the general press appears to delight in misrepresenting the members of our common calling, and holding up them and their opinions to the ridicule of the thoughtless and the ignorant. One great object of the 'Social Science Review' is to place in its true light the study of public health, and to promote sanitary amelioration in the condition of nations as well as individuals. The present number of the Journal does more than maintain its former character, for the articles are written with greater care than could be bestowd upon a weekly paper, and possess far more than a mere transient interest. The first article is the commencement of a series on the "Diseases of Overworked Men," and it opens with the proposition that the Creator intends that man should pass peacefully from birth till the expiration of his threescore and ten or odd years, and then sink into painless death; and that premature decay, suffering, and epidemic maladies, are the consequences of neglecting or defying the laws of Nature. Some may think this hypothesis to be rather a fanciful one, but it has a certain amount of truth in its foundation, and it is expounded with great skill and eloquence. An article entitled "Legislation and Prostitution," takes a humane and merciful, but, at the same time, a common sense view of the social evil, deprecating the institution of licensed houses as on the Continent, but advocating the adoption of kinder sentiments towards the unfortunate creatures of the weaker sex who are the victims of the present state of matters. Another strong point in this Review is its determined opposition to Capital Punishment, as being repulsive to the feelings of a civilized nation, and as being ineffectual in attaining the objects for which such exhibitions are intended. The important question of the plea of insanity in criminal cases, and the definition of insanity in general, are treated with very great power, and the observations made are calculated to throw great light upon these difficult subjects, and to present them to the public in a philosophical and thoughtful aspect. In addition to the more elaborate articles, there are reviews of several works on matters of general as well as Medical interest, Abstracts of the Sciences, and a record of inventions and discoveries, together with a summary of the current events of the day. We strongly recommend this Review to the notice of our Professional brethren, and, through their influence, to the general public.

"JOURNAL OF PRACTICAL MEDICINE AND SURGERY."

Accidental Constriction of the Vagina, with Disease of the Cervix.

Mr. Jobert de Lamballe invited the attention of his pupils to an interesting case of partial obliteration of the vagina. The patient, a woman of thirty-five, was to all appearance endowed with a vigorous constitution, but the extreme paleness of her countenance bore witness to the fact that she was much weakened by the loss of blood. On inquiry it was ascertained that this woman had been greatly debilitated by the frequent recurrence of uterine hæmorrhage, and at the period of her admission into the wards, she further complained of pain in the back, abdomen, and limbs.

These various symptoms distinctly pointing to disease of the womb, Mr. Jobert proceeded to an examination *per vaginum*, but scarcely had his finger passed the orifice, when its further progress was checked by the presence of an unlooked for impediment, in the shape of a smooth diaphragm pierced at its centre by an aperture large enough to admit the tip of the finger, and to allow the escape of blood or other discharges from the womb. The disease, therefore, consisted of two separate elements,—constriction of the vagina, and an unknown affection of the uterus.

Glancing at the nature and more usual causes of these constrictions, Mr. Jobert remarked, adducing facts in support of his views, that these contractions are the result of adhesions caused by local ulceration or mortification; and the latter is generally consequent on protracted labour, and sometimes, though seldom, on syphilis. Indeed, the idea of the presence of this taint in the system had suggested itself to Mr. Jobert, from the coincidence of a few copper-coloured spots and scars on the surface of the patient's thighs; but careful inquiry removed this suspicion. In the present case labour had taken place three months previously, but had been perfectly natural, lasting four hours only, and requiring no instrumental interference. This is observed more frequently than might be supposed. I am satisfied, said Mr. Jobert, that long continued pressure of the head of the fœtus on the walls of the vagina is not necessary for the production of gangrene. More than once the professor has noted that mortification followed presentations of the seat. A portion only of the walls is destroyed, the denuded surfaces throw out coagulable lymph, and the

opposite parietes become attached to each other. The same train of facts, doubtless, occurred in the present instance, and a diaphragm with a central aperture formed in consequence.

Clinical observation shows that these bands are generally very firm, and do not readily yield to mere dilatation. More effective measures are required for their removal, and Mr. Jobert proceeded as follows in the present instance.

The patient was placed under the influence of chloroform, and the diaphragm was divided in two places, from its centre to its margin. Care was, of course, taken to avoid inflicting injury on the erectile parietes of the vagina, and as the separated flaps fell loosely into the cavity of the duct, their reunion was not to be apprehended. As an additional precaution, and to effect more complete dilatation of the vagina, large tents were daily introduced, until cicatrisation was perfect. This operation permitted Mr. Jobert to examine the condition of the cervix, which he found soft and enlarged.

The summary investigation indicated the presence of local disease, the precise nature of which was subsequently ascertained.

After an interval of a few days, a speculum was introduced during anæsthesia, necessitated by the extreme tenderness of the vagina. The cause of the repeated attacks of hæmorrhage was then found to reside in the condition which Mr. Jobert denominates *hœmorrhagic hypertrophy* or *hypertrophy combined with softening of the cervix.* This organ was large, vascular and softened, blood exuded from its surface, and the antetrior labium was considerably elongated.

Mr. Jobert, in general, contends with much success with this form of disease, by the application of the actual cautery. The obstacle to local examination and treatment being now removed, this powerful agent was at once resorted to. Three cauterisations were performed at intervals of ten or twelve days, the introduction of the ivory speculum being always preceded by the inhalation of chloroform ; the softened and tumefied tissue was thus reduced to its natural dimensions, and the return of hæmorrhage efficaciously prevented. The patient, who had been admitted on the 19th of May was discharged on the 25th of July. A complete cure was by this time effected : the vagina was of small dimension, it is true, but in every respect in a healthy condition.

Mr. Jobert remarked that constrictions of this kind are not always of so complex a nature, but that they, nevertheless require surgical interposition, not only because they entirely prevent the performance of the special functions of the organ, but because they interfere with the discharge of the catamenial secretions, and the cervix continually in contact with stagnant and irritating liquids, is liable to undergo, in consequence, various morbid changes, the most common being that observed in the present case.

On the Choice of an Instrument for the Excision of Enlarged Tonsils.

The most simple and easily performed operation would seem to be the excision of the tonsils. It is daily resorted to for the purpose of removing an impediment to the freedom of respiration, or promoting the development of the chest in children, an object which, according to Dupuytren and Robert, is forwarded by the procedure ; or, on the contrary, for the removal of the tendency to constantly recurring sore throat. These various ends fully justify the performance of the operation in the child and in the adult. In the former, the enlarged tonsils, more or less overlapped by the crura of the soft palate have yet, in Mr. Demarquay's opinion, undergone no important structural change ; inflammation has not had time to alter their texture, or increase their vascularity in any marked degree ; the contrary is observed in the adult. Reiterated inflammatory action, and the various remedies applied have in general caused increase of their size and enlargement of their blood-vessels, together with a certain amount of induration ; the surgeon should be aware of these circumstances, which account for the occurrence after excision of copious and troublesome hæmorrhage.

It is often very difficult to restrain the loss of blood, and many eminent surgeons, after unavailingly resorting to the internal and external use of ice, astringents, &c., have been compelled to have recourse to the actual cautery. This, both Mr. Guersant and Mr. Blandin were obliged to do, about twenty years ago. Unless an accident of this description has been witnessed, it is impossible to form an idea of the anxiety it causes to the surgeon, or the alarm of the patients and of their friends. Iced liquids are undoubtedly appropriate in such cases, and especially the direct application of a piece of ice to the wound of the tonsil, a method recommended by Mr. Chassaignac, and beneficially adopted by Mr. Démarquay, in a case of excision of one tonsil, and of a part of the soft palate affected with cancer. The sesquichloride of iron is also a useful resource, more especially when prepared according to the formula of Piazza, modified by Mr. Adrian.

℞ Sodii chloridi purif., ℥iv. ;
Ferri Sesqui-chloridi (30° areom,) ℥vj. ;
Aq. destillatæ, ℥ij,

A piece of lint or sponge impregnated in this solution and firmly fastened to the extremity of a stick or whale bone, is conveyed to the surface of the wound, with which it is kept in close contact, until the hæmorrhage is checked. Mr. Démarquay successfully adopted this plan in two instances. But the procedure requires time ; the sponge or lint must be frequently changed ; the effect of the application is uncertain ; and the surgeon is at last obliged to rely on the actual cautery, the management of which is delicate and which is often obstinately objected to by the sufferer. One of Mr. Démarquay's patients utterly refused to submit to the operation. In this case ice and sesquichloride of iron had both failed in arresting the flow of blood, which was supplied by two small arteries. A succession of fainting fits fortunately effected the purpose which hæmostatics had proved unavailing to accomplish, and the subject recovered, after having long remained in a state of anemia. So favourable an issue cannot, however, be always expected, and Mr. Démarquay who has frequently had to contend with this formidable complication, and observed that the hæmorrhage exclusively occurs in adults, has sought for the means of preventing losses of blood, which acquire increased gravity from the fact that they may supervene several hours after the excision, and in the absence of all surgical aid.

Mr. Démarquay is convinced that the use of Fahnstock's *guillotine* instrument is somehow connected with the production of the hæmorrhage. It does not appear to have the same evil effects in the case of children. I have very frequently, says the professor, removed the enlarged tonsils of children with this appliance, and I have never met with any instance of secondary hæmorrhage. In full-grown subjects, on the contrary, whenever this accident occurred in my own practice, or in the patients of other surgeons the American instrument had been used. This result is entirely at variance with prevalent opinion, and the comparative innocuity of the appliance in the case of children is accounted for as follows by Mr. Démarquay.

When Fahnstock's *guillotine*, is used the steel circle is pressed to the surface of the tonsil, in order to engage the latter into its inner margin, the fork is then pushed forward so as to transfix the gland, and the spring is acted on to draw the diseased organ well into the ring, and remove it with greater ease. But the circular blade may merely glide over the surface of the tonsil without cutting it through, or it may force the gland entirely out of its socket, and divide its peduncle, which includes bloodvessels which have increased in size with the gradual development of the organ. When this occurs the tonsil is not, properly speaking, excised, but, as it were, scooped out, a circumstance to be noted as explanatory of the fact that the vessels are cut close to their origin. On examining the patient after the operation, a large vacant space, from which blood issues, is found to exist in the region previously occupied by the gland. This dangerous kind of enucleation is not observe

in children, because their tonsils are soft and easily divided by the blade, whereas, in the adult these organs are indurated by the frequent recurrence of inflammation, and resist the effort of the sharp semilunar blade.

The practical inference from these remarks is that, in full-grown subjects, the knife is preferable to the American contrivance. Mr. Démarquay usually employs Blandin's bistoury, with which the surgeon removes only a predetermined portion of the diseased organ; if the operation has been dexterously performed, no hæmorrhage need be apprehended. Blandin objected altogether to Fahnstock's instrument, for the reasons alleged by Mr. Démarquay. In the case of children, however, Fahnstock's *guillotine* may be used with advantage; the excision is performed more expeditiously than with the knife, and secondary hæmorrhage does not appear to be promoted by its adoption.

IRISH MEDICAL "MEMS."

(From our Dublin Correspondent.)

There is at present waging between the King and Queen's College of Physicians and the Senatus of Trinity College a lawsuit, the result of which cannot but be looked forward to with interest by every medical practitioner on both sides of the channel, as it involves the determination of a question which has been often mooted, but never decided, whether the former corporatiou has the power of conferring the degree of M. D. upon its members. The Senatus of Trinity argue that the spirit of their corporation is of a different character; that they were chartered for the superintendence of practitioners; for the suppression of empiricism; for the inspection of apothecaries' shops and weights; and for other similar duties, while the Board of the King and Queen's maintain that they were established not merely for the foregoing objects, but for the tuition of Medical science, and for conferring degrees; so that as Addison makes Sir Roger de Coverly utter this apophthegm,—

"There is much to be said on both sides,"

It will now, we trust, be definitely settled, and the rights of the College either being established by the law, it will proudly raise its front as high as its rivals, and its members will fearlessly carve upon their brass-plates the symbolic combination M. D., or the alleged right being declared null and void, it will be consigned, with all funereal honors, to "the tomb of the Capulets." In consequence, perhaps, of this law suit, we have now almost obtained the Eldorado for which, upwards of half a century, students of limited time and income have been sighing; for Trinity has made a move in the right direction, and has done away with some of the restrictive measures which prevented hundreds of Irish students from taking out their medical degree, thereby compelling them to migrate to the modern Athens where, with the loss of little time and money, they obtained a degree which fully qualified them to practise Medicine. On an average there are two thousand four hundred and forty medical practitioners in Ireland, and the majority of these practise medicine beneath the ægis of a Scottish University, and thus a considerable amount of money was turned into another channel, which might have been secured at home by a moderate concession, on the part of Trinity, to the exigencies of the times.

The long period of graduation, necessary for taking out a degree in Arts, was the great preventive to our Irish students making Trinity their *alma mater*. We may divide our Medical students into three classes, those who can command time and money, those who have money, but who are unwilling to lose an *annus medicus*, and those who have not a superfluity of either money or time.

Trinity legislated essentially for the former, who were the fewest in number, while the latter were compelled to content themselves with a Scotch or foreign diploma.

Now, a student can enter for the diploma by passing one examination in general literature, and he can acquire the necessary information whenever opportunity suits, for he has now learnt that knowledge is the same wherever acquired, and that Cicero can be read with as much profit by the banks of the Shannon as by the yellow Tiber; and Horace, Homer—*et id genus omne*—can be learnt amidst the wilds of Connemara or the mountains of Kerry, by the hedge-side and in the Grammar school, as well as beneath the shadow of the classic walls of Trinity College, Dublin. It appears that there is a diminution in the number of students in London and Edinburgh. Dublin, too, has experienced the same change by a falling off of some hundreds; sufficient causes have been at work, to the agency of which we may attribute this diminution in the number of students who throng to Dublin to pursue their Medical studies. Within the last twenty years, a series of calamities, unparalleled in the history of any country, fell upon Ireland, reducing a fifth of her population to penury, and compelling the people to take away their Penates and seek in a foreign country the sustenance which their own shores did not afford.

Quam multa in sylvis autumni frigore primo
Lapsa cadunt folia aut ad terram gurgite ab alto
Quam multæ glomerantur aves, ubi frigidus annus
Trans pontum fugat, et terris immittit apricis.

Thus did they leave Ireland, and within that period the population decreased from eight to five millions, and consequent on this diminution we have a decrease in the numbers of every profession. The Dublin School, too, attracted students from England and the colonies, when Harrison demonstrated anatomy at the College of Surgeons, and Colles lectured at Stephens's, when the Richmond possessed Carmichael, Trinity Stokes and M'Cartney, and when John Kirby, that *rara avis in terrâ*, held forth in the now far-famed Peter street, and illustrated to embryo Army surgeons the work on a battle field by firing at rows of dead bodies and then extracting the bullets, tying the arteries, and performing every possible operation to the edification and wonder of his young pupils.

In addition to these attractions, *ut ita dicam*, we had others more enticing. The study of anatomy could be pursued in Dublin at less cost and with greater facility than either in England or Scotland. What in England was looked upon as a crime of the darkest hue and visited with punishment as a felony, was here openly recognised by the law.

Resurrectionism was in the ascendant, and tradition still lingers round a spot famed in the annals of anatomical progress in Ireland called Bully's Acre; and stories are still rife of the nightly scenes of violence, and often bloodshed between the resurrectionmen and the watchers by the newly buried dead.

On the introduction of a better system of supplying subjects, the star of resurrectionism waned and gradually died out, so we lost the influx of foreign students, as demonstrations can now be taken out as cheaply in any of the schools of England as in Ireland. Our societies are now in the full swing of operation. At the first meeting of the Royal Dublin, an able and interesting paper was read by a rising young physician, Dr. E. Mapother, "On the Diet of the Irish Labourer." At the Pathological Society held Dec. 12, Dr. Beatty exhibited two ovarian tumours removed by ovariotomy in cases terminating favourably, Mr. Spencer Wells being the operator in the first case, and Dr. Walshe, a Dublin surgeon, the operator in the other. Papers and specimens were exhibited by Dr. Hamilton, of Steevens hospital, Dr. Tyrell, of Jervis street, and Dr. Fleming, of the Richmond.

The Obstetrical was opened by Dr. Beatty, with an able address. At its second meeting Dr. Walshe described the case of ovariotomy which he had performed. This was the sixth case that was operated on in this city. Since this operation three more have been performed. Below you have a list of the operations, with dates and the results.

1. The first was performed in August, 1859, by Dr. Clay. The major operation was performed. Death followed in twenty-four hours from the shock.

2. Second in March, 1862, by Dr. Kidd. Minor operation, likewise followed by death from peritonitis in twenty-four hours.

3. The third in 1862, by Dr. Gordon. The minor operation was performed. Death took place from hæmorrhage.

4. The fourth in April, 1863, by Dr. Kidd. The minor operation was also performed, but the tumour was not removed. This patient, however, recovered.

5. The fifth in August, 1863, by Mr. Spencer Wells. In this the minor operation was performed with perfect success.

6. The sixth, by Dr. Walshe. Perfect success.

7. The seventh in August, 1863. The minor operation was followed by death from peritonitis in eighty-two hours.

8. The eighth in September, 1863. The minor operation, followed also by death from peritonitis in forty hours.

9. The ninth in November, 1863. The minor operation, also followed by death. Dr. Collis, of the "Meath," was the operator.

I leave it to your readers to infer whether the results are such as would lead to the encouragement of the operation.

Dr. Collis, president of the College of Surgeons, opened the meeting of the Surgical Society of Ireland.

An old saw runs, that a "Green Christmas brings a fat churchyard;" our past one was so mild, without any of the snow or frost which are almost part and parcel of that festive period, that we shall have an opportunity of testing the truth of this. We have the usual amount of sickness amongst children from a surfeit of plum-pudding, and the different other delicacies, but no great quantity of disease is observable amongst adults.

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MR. E. CANTON, PRESIDENT.

CLINICAL DISCUSSION.

Dr. ROUTH exhibited an infant, aged eighteen months, with

HYDROCEPHALUS OF SEVERAL MONTHS' STANDING.

The case was curious as regarded the origin of the disease. A child in the same family had had hydrocephalus, said to have been from riding in a perambulator, and died in convulsions. The present infant was well up to six weeks old, when it got a fall and was injured. This had such an effect on the mother's milk that the child had convulsions, and hydrocephalus followed. The left side of the body was paralysed, yet the little patient had improved in health and intellect. It went off instantly into a fit if laid on the left side.

Mr. BAKER BROWN thought bichloride of mercury and bark, with generous diet, the best plan of treatment.

Dr. ROUTH had a great opinion of calomel in these cases, which with tonic treatment had more effect than anything he knew of. He would like to know the effects of tapping.

Dr. GIBB had seen five or six cases at the hospitals where a fatal result ensued from tapping.

Dr. GREENHALGH had had two cases equally unsuccessful from tapping.

Mr. WALTER COULSON exhibited a patient with a

LARGE SERPIGINOUS SORE OF THE GROIN.

He had applied twelve months ago with a large serpiginous ulceration in the left groin; the other groin was inoculated with the matter, which took, and was productive of a large serpiginous chancre, now nearly healed. The history of the case was strange and peculiar. He had not had a chancre for eight months before the ulceration in the groin occurred, the bubo giving rise to it, and appearing exactly eight months after the healing of the primary soft chancre —that is, there was no disease for eight months. Mr. W. Coulson thought the case almost unique, but referred to one quoted by M. Ricord, where the bubo did not appear until three years after the primary infection.

Mr. DE MERIC observed that the case should be admitted as evidence with a certain reserve, as it was difficult to ascertain to what sources of infection the patient was exposed during the eight months mentioned. Very slight sores on the generative organs might occur, pass unnoticed, and give rise to specific bubo. Nor could it be certain that the serpiginous ulceration in the groin had not arisen in a direct way unconnected with the glands of that region. He (Mr. de Meric) had seen bubo occurring four or five weeks after the healing of sores on the glans; but to suppose that eight months might elapse would require circumstances not open to doubt. He had the same misgivings respecting the case referred to by Mr. Coulson as having been seen by Ricord, or rather Puche.

Mr. COULSON still held to the view that the matter had been travelling for eight months.

The PRESIDENT exhibited

LARGE TUMOURS REMOVED FROM THE SCALP

of two patients; one from the back of the scalp, of twenty years' growth; the other from the back of the ear. The size was rather unusual, necessitating their removal from mere bulk.

Also a specimen of

FIBROUS TUMOUR OF THE UTERUS:

a good example as illustrating the ordinary rounded form, softening in one part and hardening in another. It was removed after death from a woman aged fifty years. No history could be obtained, and nothing was known of any disease during life. The uterus was sound, with a small polypus attached to it.

Mr. W. MILLER inquired if there was so much danger to be apprehended in the removal of tumours from the scalp as was supposed. He had removed several so situated, mostly of small size, and no inconvenience followed.

Mr. WALTER COULSON said it was the first time he had ever heard of danger from the operation. He had removed twenty-three from a commercial traveller in his consulting-room without bad results.

Mr. GEO. LAWSON had removed eight, six weeks ago, from a lady; the operation was followed by a violent attack of erysipelas, and her life was in great danger.

The PRESIDENT had seen erysipelas follow only in one instance. He thought it less likely to occur from large than from small tumours.

Dr. GIBB exhibited

A PIN REMOVED FROM THE LARYNX

with the aid of the laryngoscope, from a gentleman aged sixty-four, in July last. About two hours before, he drank a glass of water which contained a pin, and in endeavouring suddenly to eject it from the mouth it slipped into the larynx, where it became lodged. The most violent fits of suffocating spasm ensued at first, and recurred every few minutes. Inspection with the laryngoscope was difficult, but with firmness and perseverance it was effected, although the tongue was much swollen. The pin was seen running from before backwards, one end transfixing the right arytenoid cartilage, and the other lodged at the root of the epiglottis between the origin of the two vocal cords. The entire larynx was intensely congested, of a scarlet redness, and œdema was about commencing; the true cords were purple, the right only acting spasmodically. With the assistance of two friends of the patient, who held both him and his tongue, and with the aid of the laryngeal mirror and a pair of reliable forceps made by Luer of Paris, the pin was fortunately seized and extracted. The recovery of the patient was like magic, and nothing untoward followed.

Dr. GIBB also showed

A TOOTHBRUSH BRISTLE EXTRACTED FROM THE TONSIL,

which had given rise to great irritation, swelling, and congestion of the fauces, the symptoms of sore throat becoming alarming on the sixth day, with pain in the left ear, forehead, and neck. Its point could be felt in the tonsil by the patient and by Dr. Gibb; a powerful light with the aid of the pharyngoscope permitting this to be barely seen it was laid hold of and extracted, the throat symptoms a quickly subsiding.

Dr. GIBB then related a case of

UNITED FRACTURE OF THE POMUM ADAMI

in a phthisical lad, aged nineteen, who came under his notice amongst the out-patients at the Westminster Hospital, and who was afterwards admitted under the care o

his colleague, Dr. Basham. When eight years old he met with an accident by which the thyroid cartilage was broken at the pomum Adami; this was followed by an abscess, which burst, and the fracture was healed. The pomum was prominent and sharp, the two sides irregular and narrow, and the larynx had become narrow, as shown with the laryngoscope to many of the hospital pupils. The voice was sharp and shrill, yet feeble.

Mr. BRYANT congratulated Dr. Gibb on the success of the operation in his first two cases. He himself had a case like the last one, at the present time under observation in Guy's Hospital. A little boy, aged eight years, received a severe blow with the fist from one of his schoolfellows, which was followed by considerable dyspnœa and loss of voice. On examining the larynx he found the thyroid cartilage fractured to the right of the median line. He had not examined the throat with the laryngoscope, but would do so, as the boy could still only whisper. Ever since the injury he had been subject at night to considerable dyspnœa; and had had epistaxis on five or six different occasions following this dyspnœa.

Dr. MORELL MACKENZIE observed that the cases brought forward by Dr. Gibb were extremely interesting, as they showed that the laryngoscope could be employed with the greatest advantage in cases of extreme emergency. He especially called the attention of those unaccustomed to the use of the laryngoscope to a small sulcus situated on each side of the larynx, as being especially liable to receive and retain foreign bodies. This sulcus was bounded on the inner side by the aryteno-epiglottidean fold, and on the outer side by the wall of the pharynx; its base was formed by the greater cornu of the hyoid bone. Dr. Mackenzie stated that he had frequently found particles of undigested food collected in this fossa, and he should therefore recommend its careful examination in cases where small foreign bodies were supposed to have been lodged in the larynx.

Mr. DE MERIC inquired if in impending suffocation it was proper to use the laryngoscope, and whether in such a case it was easy to introduce the instrument.

Dr. GIBB replied that it was truly remarkable with what facility the laryngoscope could be used in some of these painfully acute cases, such as foreign bodies like the one related, acute laryngitis, urgent suffocative dyspnœa, &c. In his first case, if the pin had not been extracted from above, it would have been necessary to perform tracheotomy then and there. He had seen crumbs of bread, broken teeth, and other substances lodged in the fossa spoken of by Dr. Mackenzie, but there was nothing novel in the description he had given of it.

Mr. ERNES HART exhibited and gave clinical details of

CASES OF OPHTHALMIC DISEASE PATHOGNOMONIC OF INHERITED SYPHILIS.

In these cases, the characteristic notching of the teeth and the character of the interstitial inflammation of the cornea had been useful in directing attention to the probability of a syphilitic taint of the parents as the cause lying at the bottom of the diseases in children. Inquiry into the history in the three cases detailed had given ample confirmation of the suspicion thus engendered. In one of the cases this had been especially useful, inasmuch as the ophthalmic disease had been considered primarily as of the ordinary scrofulous character, and non-specific remedies had altogether failed to arrest the progress of the malady. One eye had thus been lost, and the other was gravely compromised; it had, however, considerably recovered under the use of mercurial inunctions, and subsequently of iodide of potassium; but vision would probably continue imperfect, owing to the extent to which the sloughing of the cornea had already proceeded.

Mr. COULSON said there was one condition Mr. Hart had not referred to—namely, the great depth of the palate.

Mr. HART said it was well marked in this child.

Mr. DE MERIC cited a case brought to him at the hospital labouring under hereditary syphilis. The great peculiarity of the child (ten months old) was that it was blind, yet no change could be seen in the eye. Most of the hereditary symptoms disappeared, but years elapsed before the sight was quite restored.

Mr. BRYANT cited another case where the diagnosis was very difficult, but determined by the state of the teeth; it was treated as syphilis, and a rapid recovery followed.

The PRESIDENT asked whether Mr. Hart and Mr. Coulson observed the state of the teeth in those cases where the arch was deeply developed, but where there was no evidence of syphilitic inheritance.

Mr. COULSON had often seen deep arching without any notches of the teeth, or other peculiarity in them, excepting that they projected forward. He had always seen it in hereditary syphilis.

Dr. PLAYFAIR related a case of

INFANTILE PARALYSIS.

in a child, aged two years, with paralysis of both legs; in the left was some power of motion, but no sensation in either. The right arm was also paralysed. All the paralysed parts were of a livid colour; the muscles soft and flaccid; could scarcely take her food. At present she has diarrhœa, for which she was brought to King's College Hospital. He thought it very rare to meet such cases where the paralysis was so extensive as in this. Dr. West had tabulated thirty-two cases in his work "On Diseases of Children;" in one only were the upper extremities affected as well as the lower, following remittent fever attended with convulsions. In Dr. Playfair's case there was no convulsion, and the attack came on quite suddenly.

OBSTETRICAL SOCIETY OF LONDON.

DECEMBER 2ND, 1863.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows:—Drs. Davis, Savage, and Swyer; Messrs. Bryant, Chisholm, Griffiths, Morgan, and Sequiera.

Dr. Gervis and Mr. Ray were appointed auditors.

Dr. BARNES exhibited and described a new

CRANIOTOMY FORCEPS.

It combined the advantages of the instruments of Professors Simpson and Murphy, and by a further contrivance added by Dr. Barnes, was rendered much more effective than any other instrument with which he was acquainted. The elbow on the inner blade, allowing free room for any fold of scalp at the point of perforation, permitted the duck-bill-toothed portions of the blades to be pushed high up to secure a firm hold of the cranium, without the danger of straining the lock. By this means the blades were always kept in perfect parallelism, ensuring a widely-diffused grasp of the cranium, and avoiding the risk of tearing away. Having properly seized the cranium, it became a point of great importance to secure the hold in a manner to save the operator the fatigue and muscular strain of pressing the handles together, whilst at the same time considerable extracting power is required. For this purpose he had adapted a powerful screw which united the extremities of the handles, setting the blades fast at any interval required. Another advantage provided for was the fitting the blades with a modification of the French forceps-lock, so that the instrument could either be used as one piece, or the two blades could be applied separately. The entire length of the instrument was fifteen inches. Dr. Barnes said he had used the instrument several times, and that its grasp and action were so perfect that he had never been obliged to take a fresh hold. It was made by Weiss.

Mr. BAKER BROWN read a case of

OVARIAN DROPSY,

which had three years and a half ago been treated by him with tapping and pressure, with apparent recovery for three years and a half. The cyst, however, began at the end of that date to enlarge, and the patient, being in good health, was recommended by Mr. Brown to submit to ovariotomy, which was performed by him at the London Surgical Home in the usual way, with a very small incision. The cyst was nearly unilocular, but was not of the ovary, which was healthy and free, but in the broad ligament; the pedicle was broad. She recovered without a bad

symptom, and is now well. Mr. Brown considered the case of especial interest just now, proving that no adhesions were produced by the previous tapping and pressure.

The report of the committee (Dr. Tyler Smith and Dr. Braxton Hicks) appointed to examine a specimen of Extra-Uterine Fœtation, in which two fœtuses were found in connection with the same Fallopian tube, was read. They considered that the smaller fœtus was the result of a former conception, and was attached to the fimbriated portion of Fallopian tube in such a manner as not to impede a subsequent conception, which also remained extra-uterine about the middle of the tube, from the bursting of which the patient had died.

Dr. J. BRAXTON HICKS read a short appendix to his paper on

COMBINED EXTERNAL AND INTERNAL VERSION,

in which he stated that in consequence of not having seen Wigand's memoir, he was unable at the last meeting to reply to the statement made by Dr. Barnes, that he had *fully* described internal and external version. Since that time he (Dr. Hicks) had been able to go over the work, and took exception to the above statement as far as regards internal version. In comparing this memoir with his own paper, he pointed out that although in regard to cephalic version there was much similarity in the two plans, still that Wigand had no knowledge of pushing on the child from within, in the direction of its head, so as to produce podalic version; that he had never adopted complete podalic version, and he makes no mention of the way to convert a more or less cephalic version into podalic. Wigand's plan was to bring that part to present which was nearest the orifice of the uterus. Therefore he applied it only to the rectification of *abnormal* presentations. Consequently, on comparing the two methods, it would readily be seen that very many of the conditions to which Dr. Hicks applied his plans were contra-indicated in the other as mentioned by Wigand himself. It was shown that the only use he makes of the internal hand is to first determine the presentation, and to receive the part as it is pressed down from above, and guide it to the os uteri. Dr. Hicks again pointed out that it was by combining the two powers, within and without, that made the plan he had brought forward much more complete and available than either employed separately.

Dr. GERVIS exhibited the body of a child, in whose birth, after the passage of the head, extreme difficulty was experienced in completing the delivery, owing to a great enlargement of the abdomen. It was, however, accomplished by simple traction. On dissection this enlargement was found to be due to an enormously distended uterus, presenting two distinct cornua, and with an imperfect septum dividing its cavity. It was filled with a turbid serum containing white flocculi. The os uteri was impervious. There was no indication of an anus, and the rectum terminated in a cul-de-sac attached to the posterior part of the uterus.

The PRESIDENT remarked that it was a most interesting specimen, and suggested that Dr. Gervis should, jointly with Dr. Hicks, furnish a further report upon it.

Dr. J. BRAXTON HICKS read three cases of

ABNORMAL CONDITION OF FŒTUS

which had caused impediment to labour. One in which there was found three quarts of ascitic fluid, in combination with cystic enlargement of the pelvis of both kidneys, in consequence of occlusion of the ureters. Another, in which the abdomen of a female fœtus was distended by the bladder, which reached to the ribs, and which was full of fluid. No obstruction existed in the urethra. Both were delivered readily after puncture by the crotchet. In the third there was dropsy of the amnion to an enormous extent, coupled with a very peculiar enlargement of the forepart of the neck of the fœtus, which had to be ruptured before labour could be completed. It was partly filled with serous fluid. The mothers in all the cases recovered.

Dr. GRAILY HEWITT remarked that the occurrence of cases such as those brought before the Society by Dr. Hicks favoured the idea that normally a secretion and excretion of urine from the fœtus was going on during intra-uterine life. He alluded to cases recorded by Mauriceau and Depaul similar to Dr. Hicks's case.

Dr. Hicks was invited to report further on the tumour, conjointly with Dr. Gervis.

Dr. LUMLEY EARLE (Obstetric Surgeon to the Queen's Hospital, Birmingham), read a paper

ON DISTENSION OF THE BLADDER CONSIDERED AS A CAUSE OF POST-PARTUM HÆMORRHAGE.

The author pointed out this condition as one of the many causes of post-partum hæmorrhage; and called attention to the propinquity of the bladder to the lower portion of the uterus, so that when the former was distended the latter was not only displaced, but prevented from contracting completely. He pointed out the usual symptoms which would lead to the discovery of the accumulation of urine; and gave three cases in illustration that the removal of urine caused the subsidence of the flooding.

Mr. RICHARD MARLEY read a paper

ON PERTUSSIS: ITS PRACTICAL TREATMENT AND MORE RAPID CURE.

After alluding to the history and symptomatology of this complaint, the author analyzed the various modes of treatment. He laid stress upon the value, in the second stage, of conium, belladonna, and hydrocyanic acid taken internally; and also the careful inhalation of chloroform at the commencement of the attack, whereby the fit was invariably mitigated or stopped. Although he had by the use of the above treatment been led to think very favourably of it, yet he did not urge it to the exclusion of all others. As in all other diseases, the treatment must be modified by the special features of each case. He advocated warmth during the first stage, and change of air in the third.

Dr. DAY thought it was scarcely safe to leave chloroform in the hands of nurses. He considered that the disease should be treated on general principles. Bromide of ammonium had been latterly much recommended, but in the few cases in which he had tried it he had not found it to possess much influence on the disease.

Dr. HOLT DUNN thought that the treatment in whooping-cough was uncertain, and that we should hail with pleasure any plan which gave more satisfactory results. He had tried the last-named drug, and thought he had found more success with it than with any other.

Dr. GRAILY HEWITT had some years ago examined carefully into the causes of death from whooping-cough. In the cases he had examined, which were for the most part children badly fed, ill-nourished, and in other respects diseased, death had occurred from collapse of the lung—a condition formerly described as lobular pneumonia. It was useless to attempt to treat such cases by specifics. In all cases of whooping-cough he had found the greatest benefit from a treatment mainly consisting of hygiene—good food, exercise, warmth, ventilation, &c. Antispasmodics and sedatives were frequently required, and were not seldom of great use; but the primary object of the treatment should be to maintain the general health of the child.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On the 28th ult., the wife of Dr. Adams, of Green-street, Sittingbourne, Kent, of a daughter.

BUTLER.—On the 1st inst., at Lower Norwood, the wife of Surg.-Major J. H. Butler, of the Bengal Medical Staff, of a son.

COCKERTON.—On the 29th ult., at Petersham terrace, South Kensington, the wife of Richard Cockerton, M.R.C.S.E., of a son.

LINEKER.—On the 6th inst., at Leighton Buzzard, Beds, the wife of E. H. Lineker, M.R.C.S.E., of a son.

PRIEST.—On the 31st ult., at Waltham-Abbey, the wife of Arthur Priest, M.R.C.S.E., of a daughter.

REDFORD.—On the 28th ult., at Normanton, Yorkshire, the wife of George Redford, L.F.P. & S. Glas., of a son.

MARRIAGES.

KERNOT—CLARKE.—On the 5th inst., at Gabriel's Church, Belgravia, C. M. Kernot, M.D., of West Cowes, to Eliza,

widow of the late M. Clarke, Esq., of Hillfield Lodge, Clifton, Bristol.

MOORE—WOOD.—On the 24th ult., at the Cathedral, Manchester, Thos Moore, M.R.C.S., second son of Thomas Moore, M.R.C.S., late of Wilmslow, to Rebecca, widow of the late John Wood, Esq., of Heathfield, Didsbury.

WILSON—INGLEBY.—On the 5th inst., at Pateley bridge, J. Wilson, M.R.C.S.E., of Whitby, to Eliza, daughter of J. Ingleby, Esq., of Pately bridge.

DEATHS.

BEETSON.—On the 2nd inst., at Auckland Villa, Southsea, G. Beetson, late Superintending Surgeon Madras Army.

CROW.—On the 2nd ult., at Madeira, J. W. Crow, M.R.C.S.E., Staff Assist.-Surg. Army.

DAVIS.—On the 1st inst., at Royal Crescent, Bath, J. F. Davis, M.D., aged 90.

DERBISHIRE.—On the 31st ult., ot Upper Marylebone street, John Derbishire, M.R.C.S.E., aged 71.

FOSTER.—On the 16th ult., S. Foster, L.R.C.S.Ed., of Northwich, Cheshire.

HASLEWOOD.—On the 30th ult., at Cradley, Worcestershire, G. Haslewood, Surgeon, aged 64.

HUTSON.—On the 13th of Oct., at Demerara, J. R. F. Hutson, M.D., aged 67.

MCKERHNIE—On the 2nd inst., at Ryde, Isle of Wight, Elizabeth Twigg, only daughter of Dr. McKerhnie of Greenhill, Paisley, N.B., aged 18.

O'MULLANE.—On the 21st of Oct., at Bourke street, West, Melbourne, A. O'Mullane, M.D., aged 51.

PENBERTHY.—On the 17th ult., at Redruth, John Penberthy, jun., Surgeon, aged 29.

SINCLAIR.—On the 26th ult., at Southsea, A. Sinclair, M.D., Staff Surgeon.

SLEIGH.—On the 30th ult., at Brixton, Wm. W. Sleigh, M.D., aged 67.

THOMSON.—On the 27th ult., at Abbotsford place, Glasgow, *Dr. D. Thomson*, aged 82.

WARD.—On the 31st ult., at Angel terrace, Paradise road, Stockwell, F. Ward, M.R.C.S. Eng., late of Balham-hill, aged 57.

WILSON.—On the 3rd inst., at Elmbank, Dunoon, Argyleshire, R. Wilson, M.D.

MEDICAL NEWS.

UNIVERSITY OF LONDON: SECOND M.B. EXAMINATION, 1863.—*Examination for Honours.*—Surgery: 1st Class—Jas. Beddard, Guy's, Scholarship and Gold Medal; Phillip Henry Pye-Smith, Guy's, Gold Medal; Thomas Stevenson, Guy's; Walter Rivington, London Hospital. 2nd Class—Julius St. Thomas Clarke, Guy's; Arthur Wellesley Edis, Westminster Hospital—Medicine: 1st Class—John Talfourd Jones, University College, Scholarship and Gold Medal; Philip Henry Pye-Smith, Guy's, Gold Medal; Thomas Stevenson, Guy's; James Beddard, Guy's. 2nd Class—Frederick Thos. Roberts, University College; Henry Thomas Lanchester, St. Bartholomew's; John Wale Hicks, St. Thomas's. 3rd Class—Julius St. Thomas Clarke, Guy's; James Gwyther, Manchester Royal Infirmary; Arthur Wellesly Edis, Westminster Hospital.—Forensic Medicine: 1st Class—Thos. Stevenson, Guy's, Scholarship and Gold Medal; John Talfourd Jones, University College, Gold Medal; Julius St. Thomas Clarke, Guy's; Walter Rivington, London Hospital, and Frederick Thomas Roberts, University College, equal. 2nd Class—James Beddard, and Phillip Henry Pye-Smith, Guy's, equal; James Gwyther, Manchester Royal Infirmary. 3rd Class—Arthur Wellesly Edis, Westminster Hospital, and John Wale Hicks, St. Thomas's, equal; Wm. Henry Axford, King's College.—Midwifery: 1st Class—Thomas Stevenson, Guy's, Scholarship and Gold Medal; John Wale Hicks, St. Thomas's, Gold Medal; Philip Henry Pye-Smith, Guy's; James Beddard, Guy's. 2nd Class—Julius St. Thomas Clarke, Guy's; Gwynne Henry Harries, King's College; John Talfourd Jones, University College; Frederick Thos. Roberts, University College. 3rd Class—Jas. Gwyther, Manchester Royal Infirmary; Walter Rivington, London Hospital.

LECTURES AT THE COLLEGE OF PHYSICIANS.—Dr. G. Johnson has applied to the Council of the College for permission to deliver some lectures on the Laryngoscope, and his request has been granted.

Mr. SKEY on Monday last formally resigned the office of Surgeon to St. Bartholomew's Hospital. Mr. Holmes Coote succeeds him.

H. T. LOMAX, M.R.C.S. Eng., has been placed in the Commission of the Peace for the borough of Stafford.

TEMPORARY ORDERS FOR MEDICAL RELIEF.—On Monday evening the guardians of Bethnal green directed their relieving officer to discontinue the issue of "one day medical orders," in consequence of the system operating to the prejudice of the poor needing medical assistance. The issue of "one day midwifery orders" has been already forbidden by the Poor-law Board.

A TRIBUTE OF GRATITUDE TO PROFESSOR OPPOLZER OF VIENNA.—The students of the University of Vienna have presented Professor Oppolzer with his bust in marble as a token of their recognition of the liberal and paternal manner in which he governed the University during his rectorship. The presentation took place before a vast concourse of professors, friends, and students.

NEW INVENTIONS—"OXYGENESIS."—Mr. Robbins, of the firm of Garden and Robbins, of Oxford street, has discovered and patented a new and and most simple process for evolving oxygen gas. The substance yielding the gas, a peroxide, is a dry yellow powder which will keep in a well-stoppered bottle for any length of time. When required for use, a portion of the powder is placed in a common flask having an escape tube, and a little dilute sulphuric acid is added, precisely as the same dilute acid is added to zinc, when hydrogen gas is evolved. So soon as the acid is added, the oxygen begins to pass off, and the supply is so abundant that one ounce of the powder yields fifty ounces, by measure, of oxygen. It is difficult to state to what useful purposes this discovery may not be applied. For the lecture-room, and for all experiments with oxygen, it is the most ready method of obtaining a supply; indeed it leaves nothing to be desired. In the hospital ward, when oxygen is wanted, there it is at hand; and so readily at hand, that a nurse may learn at one lesson how to set it free. In analyses, and in the laboratory at all times, the new process of obtaining oxygen will be the most convenient; while in the Arts the discovery has but to be known to ensure its general acceptance. Amongst its first application in the Arts, will probably be its employment with hydrogen, or with coal-gas, for the oxy-hydrogen microscope, and for illuminating purposes. Mr. Robbins has designated his process "Oxygenesis."—'Social Science Review.'

ANNIVERSARY MEETING OF THE HARVEIAN SOCIETY.—The annivery meeting of this Society was held on Thursday evening last, when the President and Council opened the room for a *soirée*, which was very numerously attended. The President, Dr. Fuller, delivered a discourse relating to matters connected with public health, alluding, among many similar topics, to the necessity of efficient vaccination, and to the risks which may sometimes be incurred by vaccination from a child, which although apparently well, may really be labouring under hereditary disease. A great number of interesting objects was exhibited to the company, and Dr. Gibb and Dr. Morell Mackenzie both exhibited their respective laryngoscopes, the first demonstrating the physiological action of his own larynx, and the second demonstrating some granular excrescences on the larynx of a patient. Mr. William Adams was elected President of the Society for the ensuing year. It appears that the Harveian Society is in a flourishing state, and that from the low rate of the subscription, and from the pleasant *réunions* which are afforded by the meetings, it is highly appreciated by the Profession, especially those who reside at the Oxford street end of Hyde Park.

ADDENBROOKE'S HOSPITAL.—At the last quarterly court of the Governors of Addenbrooke's Hospital, Dr. Paget, having served as physician for a second period of twelve years, tendered his resignation. He pursued the same course in 1851, when, at the request of the governors, he withdrew his resignation. A complimentary vote of thanks

was passed, and he was again requested to continue his services, with which he at once complied.

THE LATE MR. GREEN AND THE VETERINARY COLLEGE.—In May 1819, he was unanimously chosen a member of the Board of Examiners of the Royal Veterinary College, to supply the vacancy caused by the death of the younger Cline. Associating himself in the performance of these duties with the late Mr. Abernethy, Dr Babington, Dr. Baillie, Sir A. Cooper, Dr. Cooke, Henry Cline, Sir E. Home, Dr. Pearson, J. Wilson, and Professors Coleman and Sewell, he lived to see all these carried to the tombs of their fathers, and to have for his colleagues an entirely new company of worthies. On the attainment of the Charter in 1844, Mr. Green continued his connection with the College until the formation of a permanent board, when he resigned, receiving the thanks of the Council for his distinguished and eminently useful services.

TRAINED NURSES FOR TURKEY.—Miss Nightingale, whose continued delicate state of health, we regret to state, causes her many friends much uneasiness, has expressed her intention, through Dr. Foote, of Constantinople, of training, at the expense of her fund, properly recommended persons to serve as nurses in that city. The want of such attendance has been long severely felt, the only existing provision of the kind being that afforded by the Sisters of Charity, the Prussian Deaconesses, and a few ill-trained midwives, who afford but very inadequate supply for the demand of their services.

UNPROVED CHARGE AGAINST A MILITARY SURGEON.—A court-martial has been held at Woolwich on an assistant-surgeon in the army for conduct unbecoming an officer, in drinking intoxicating liquors to such excess as to produce illness, by which he was incapacitated for the performance of his duties. The court held that the charge was not proved, and acquitted the prisoner.

DEPUTY-INSPECTOR-GENERAL OF MALTA HOSPITAL.—Dr. Charles Abercromby Anderson has been appointed by the First Lord of the Admiralty to be Deputy-Inspector-General of Malta Hospital, vice Dr. A. Armstrong, to be superseded at his own request. Dr. Anderson served as an additional assistant-surgeon in the 'Camperdown,' 104, flag ship at Sheerness, in 1841 and 1842; in the 'Queen,' 110, and 'Formidable,' 84, flag-ships in the Mediterranean, in 1843 and 1844; was an assistant-surgeon at Greenwich Hospital in 1846; and in the 'Asia,' 84, in the Pacific, in 1847 and 1849, when he was promoted to be surgeon and appointed to the 'Gorgon,' 6, in which he remained till the close of 1851. He served in the 'Blenheim,' 60, and 'Exmouth,' 90, from 1854 to 1856, when he was appointed staff-surgeon on the 'Calcutta,' 84, where he continued until he was promoted to be deputy-inspector-general of hospitals and fleets, 1858. He was appointed deputy-inspector-general at Hong-Kong, where he remained till 1860.

ERRATA.—Pp. 13, column 1, of MEDICAL CIRCULAR, Jan. 6.
Line 7 from top, for "Orgaron" read "Organon."
Line 2 from bottom, for "Vesariæ" read "Vesaniæ."
Line 20 from bottom, for "profuse fevers" read "impure fevers."

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JAN. 13. — *Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Hunterian Society, 8 p.m.—Dr. Daldy, "On the Influence of Feeble Heart upon Disease."

THURSDAY, JAN. 14.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m..

FRIDAY, JAN. 15. — *Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, JAN. 16.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.

MONDAY, JAN. 18. — *Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JAN. 19.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.; Anthropological Society of London, 8 p.m.—R. Lee, Esq., B.A., M.R.C.S., "On the Extinction of Races," T. Bendyshe, Esq., M.A., "On the Extinction of Races."

BOOKS RECEIVED FOR REVIEW.

The Science and Practice of Medicine. By Dr. W. Aitken. In two volumes. Second Edition, Revised and Re-written. London: C. Griffin and Co., Stationers' Hall Court.

The Journal of Mental Science. January, 1864.

Functional Diseases of Women, Cases Illustrative of a New Method of Treating them through the Agency of the Nervous System by Means of Heat and Cold. By J. Chapman, M.D. London: Trubner and Co., Paternoster row.

Essays on Digestion. By the late J. Carson, M.D., &c. London: Longman and Co.

The Diseases of Women. By Dr. Churchill. Fifth Edition. Dublin: Fannin and Co.

Observations on the Present State of Medical Education. By J. Syme, Esq., F.R.S.E. Edinburgh: Edmonston and Douglas.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

F. R.—The delay in the publication of the 'Medical Directory' arises from the very proper desire of the Editors to include in the New Edition, the name of every person who was registered up to Jan. 1st, thus adding considerably to the value of the work.

THE ANTHROPOLOGICAL SOCIETY.—The notice has been received.

MESSRS. T. & H. SMITH.—The paper on the new alkaloid found in Aconitum Napellus has been received.

Dr. L.—The subject shall receive attention.

A. X. A.—The rarity of phthisis in warm climates may be explained in some measure by—1st. There are not the sudden and extreme changes of temperature.—2nd. The thorough ventilation enjoyed in all the houses, which being large and kept open night and day admit the air freely and completely, and in as pure a state as it is circulating outside.—3rd. The circumstance, that the lungs are not over excited; in fact, they have less work imposed, since there is not the same occasion for the oxidation of the carbon, the external heat being so great, as to remove the necessity of its evolution from the system, which in those countries is always sufficiently heated. The lassitude caused by heat is a wise arrangement of Nature to provide against too great excitement of the nervous and muscular systems, already stimulated or excited beyond their wonted extent.

INVALID.—Dr. Arnott's Hydrostatic Bed, made by Spencer and Co., Billiter street, City, is well worthy your inspection. It has been before the public many years, and is highly approved and adopted by the Medical Profession.

V.—It is very dangerous to use a cold immediately after a warm or tepid bath, since by the latter there is a mere relaxation of the skin; after a hot bath, however, the effect is different because then the skin has been well stimulated and has the power of responding to the further stimulus of cold.

INQUIRER.—Thanks! we have seen such an advertisement as the following:—

"Great Discovery in Homœopathy,—It is found, that all homœopathic medicines are simultaneously administered only that one, which tallies with the disease will act and the rest will be inert. The salt of life contains a mixture of all homœopathic medicines, so compounded as to prevent chem

cal reaction, and it cures all diseases by presenting all remedies to the system, leaving the election of the proper one to nature.—Patented and prepared by Hahneman, Williams, and Co."

We have extracted the above from 'The Dublin Medical Press,' which gave it as a specimen of how far humbug may be carried.

L.M.—We know not in whom the fault lies; but it is a fact that the L.M. of the celebrated and chartered Dublin Lying-in-Hospital cannot be registered.

SYMM *v.* FRASER AND ANDREWS.

In answer to Dr. Tunstall's letter, Dr. Fraser has addressed the following to the Editor of the 'Medical Times and Gazette.'

SIR,—The Profession has so unequivocally and handsomely expressed its sentiments respecting the above iniquitous prosecution, that I most unwillingly trouble you with any reference to it; but, in justice to my co-defendant and myself, I cannot allow to pass unnoticed a letter which appeared in your last number from Dr. Tunstall, of Bath, in which he states that the evidence he gave theoretically was confirmed practically by the defendants. This is certainly "the unkindest cut of all," making it appear that we confirmed evidence which I have not heard spoken of, in or out of the Profession, except in terms of ridicule and grave censure.

Dr. Tunstall stated in evidence that he first visited the patient on January 24, 1862, at 10 p.m.; that he found her in a very nervous, excited condition, complaining of pain in her leg, and oppression of the chest; he stated that at first he had a suspicion in his own mind that the excitement he saw might have been produced by drink, but that on inquiring whether she had taken any, she said—"No." Dr. Tunstall further stated in evidence,—"I then proceeded in my investigation, and I am perfectly of opinion that all the symptoms I saw might have arisen from *travelling* gout." Dr. Tunstall added that he saw her at 10 a.m. on the following morning, when she was much better, and left Bath. Now, Sir, this theory of "travelling gout" was one of the strongest points on which Mr. M. Chambers dwelt in his address to the jury, whom he endeavoured to make believe that the state of drunken, ungovernable excitement in which the patient was, during my sixty hours' attendance on her, was produced by "travelling gout." So far, therefore, from confirming Dr. Tunstall's hypothesis, I believe it to be as visionary and baseless as any ever invented by counsel, to "make the worse appear the better reason;" and I cannot help designating his conduct as most cruel, in bringing forward a wild theory, and thereby aiding a weak-minded, vindictive, ill-advised woman in her endeavour to injure those who had humanely befriended her. The "very nervous, excited condition" in which Mrs. Symm was when Dr. Tunstall saw her, is fully accounted for by the evidence of numerous trustworthy witnesses, who deposed to her suffering from delirium tremens, and being intoxicated for days together during the latter part of Dec. 1861; also by the evidence of Dr. Barnes, who, on his last visit in January, found her "in a state of helpless intoxication." Mr. Barrett, who attended the patient in Bath from January 12 to 21, and who appeared as a witness for her, somewhat reluctantly but candidly said he was bound to state his impression as to her being in liquor, and as to his directions respecting her refraining from drink being unattended to.

On January 22, Mr. Bond, inspector and clerk of the police at Bath, visited the plaintiff, and found her, as he more graphically than elegantly described, "looking like a woman who had been on the spree for a week; her memory gone, talking incoherently;" and as this was on the next day but one preceding Dr. Tunstall's visit, it would be somewhat surprising if he found her otherwise than in "a very nervous, excited condition."

As to Dr. Tunstall's account of his morning visitor with a 5*l.* note and subpœna, I could found a plausible theory on the circumstance, but shall refrain, merely remarking that it is an unusual occurrence for a Medical witness to be called on to give evidence, without the individual in whose favour he is to appear, first ascertaining what that evidence is likely to be. It is, moreover, a remarkable fact, that from the commencement of the recent proceedings, my solicitor has repeatedly told me that there were to be two Medical witnesses from Bath, on whose evidence the plaintiff principally depended for a verdict in her favour: who those witnesses were, we could not ascertain until we saw them in the witness-box.

I am, &c. D. FRASER, M.D.

[Dr. Tunstall has written a rejoinder, to which we will afford insertion next week.—ED. MED. CIRCULAR.]

Royal College of Physicians of LONDON.

FIRST Part of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School, will commence on Tuesday, February 2nd.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, February 9th.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination, under special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials, required by the Bye-laws are to be left at the same time.

H. A. PITMAN, Registrar, Pallmall East.

Apothecaries' Hall.—The next Examination in Arts will be held at the Hall on Friday and Saturday, 29th and 30th of January, 1864. A Syllabus of the Subjects for Examination may be had on application.

An Examination in Arts will again be held in the months of April and September, 1864.

R. B. UPTON, Clerk to the Society.

The London Surgical Home for Dis-eases of Women, 17 and 18 Stanley terrace, Notting hill, W.

MEDICAL OFFICERS.

PHYSICIAN.

C. HANDFIELD JONES Esq., M.D., 49 Green street, Grosvenor square.

SURGEONS.

J. BAKER BROWN Esq., F.R.C.S., 17 Connaught square.

PHILIP H. HARPER Esq., F.R.C.S., 30 Cambridge street, Hyde Park.

HOUSE SURGEON.

TOM S. DAVEY Esq.

This Institution is established for the treatment of Diseases of Women. It contains 34 beds, 28 of which are appropriated to patients, who each pay a small sum weekly towards the household expenses, and 6 are reserved for poor patients recommended by Life Governors. The services of the medical officers are entirely honorary. DONATIONS and ANNUAL SUBSCRIPTIONS are earnestly requested, payable to the Treasurer, R. Ruthven Pym, Esq., the western branch of the Bank of England Burlington gardens, W.; or at the Secretary, at the Home.

W. B. HARMAN, Secretary. pro tem.

Emperor Life and Fire Assurance SOCIETY. 73 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

Education.—Private Preparatory SCHOOL for the SONS of CLERGYMEN, MEDICAL MEN, and OFFICERS of LIMITED INCOME between the ages of Six and Thirteen. The design of this Establishment is to thoroughly ground LITTLE BOYS for the Public and Private Schools. The pupils form a part of the principal family, and receive careful religious and mental training, with every home comfort.

For Prospectus, address the Principal, Hurstbourne House, Whitchurch, Hants.

N.B.—A School for a limited number of LITTLE GIRLS DAUGHTERS of CLERGYMEN and MEDICAL MEN, under Thirteen years of age (in connection with this Establishment) is conducted by Mrs. SCOTT. Apply to Hurstbourne House.

Dr. E. E. Barron continues his Courses of MEDICAL and SURGICAL TUITION, preparatory for Professional Examinations, at his new Class-Room, Millikins Chambers, Southwark Street, Borough.

Mr. G. Hind, F.R.C.S., has resumed his DEMONSTRATIONS and EXAMINATIONS at 29 Newman street, Oxford street (hours, from 10 to 12 A.M., and 6 to 8 P.M.)

Select finishing School for Young LADIES OF THE UPPER CIRCLES.—Situation particularly salubrious, in the vicinity of the Holland Park, Kensington. At present there are vacancies for two senior and two junior pupils: the elder young ladies receive instruction from one of the principals, assisted by eminent masters and resident foreign governesses. The juniors are under the supervision of another of the principals, trained and educated in a separate apartment, and prepared for the upper school-room; a good garden being attached to the house, these little ones have the advantage of frequen elaxation from study, which is so essential to health. Parents will w bear testimony. For particulars address Miss M—, care of Mr. HAR King William street, W.C.

Important.—An Opportunity pre-sents itself to place in a superior school, the son of a gentleman, who may desire his admission to Eton, &c. The advantages are great both in a pecuniary and Educational point of view.—Address, DELTA, care of Mr HARRIS, 20 King William street, Charing cross, W.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT'S Analysis gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxygen; equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.
OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera Race Glasses, and Telescopes, by the best London Makers.
Catalogue of Cameras and Lenses, also of Pocket and Dissecting Cases forwarded on receipt of Postage Stamps.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT

DR. HASSAL'S REPORT:—"I have carefully analyzed Blockley's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts.
RAGGETT, late Blockey, 21 Duke st., St. James's Established 100 years.

Dr. Caplin's Electro-Chemical Bath

and GALVANO-THERAPEUTIC ESTABLISHMENT.
9 YORK PLACE, BAKER STREET, LONDON.

Medical gentlemen and invalids who are desirous of being acquainted with the modus operandi of this new mode of applying electricity for the cure of Rheumatism, Paralysis, and all kinds of Chronic Diseases resulting from the retention of inorganic substances in the body, have to read Dr. Caplin's work entitled "Historical Records of the Various Affections cured by means of the Electro-Chemical Bath;" 56 different cases with their rationale, and preceded by an introduction on the philosophical deductions of his system, &c., 290 pages, price 1s. 6d., at Baillière's, 219 Regent street, and at the Author's establishment.
N.B.—Medical and Scientific gentlemen are invited to visit the Institution. They will be admitted by presenting their card.

The Pneumoclime.—An Address to

the Profession, by Mr. JEFFREYS, on this his latest improvement the RESPIRATOR, and proposing another climate instrument, the PNEUMOTHALP.—Through a typographical omission, the above letter was printed without its Author's address—"Belvidere road, Upper Norwood, Surrey, S."

John W. Tweedie, Publisher, 337 Strand, is Chief Agent for the PNEUMOCLIME, in its several forms of Oral, Hand-Oral, Day and Night OrinaSals, and Nasal.

Whicker and Blaise, late Savigny

and Co., Wholesale and Retail Cutlers and Surgeons' Instrument Makers, No. 67 St. James's street, from Pallmall and King street, London, and at their Manufactory, Young's place, Wood street, Westminster.

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 9s. 8d. Households (recommended for bread-making), 9s. 0d.; Seconds, 8s. 4d.; Wheat Meal for brown bread, 8s. 4d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

White's Sacchaiized Hydrate of

MAGNESIA.

For INFANTS and FEMALES it will be found an invaluable remedy.
From its agreeable and pleasant taste, it has the advantage over all other preparations of Magnesia, as the most susceptible stomach will not reject it.

SOLE MANUFACTURERS AND PROPRIETORS,
BOILEAU and BOYD, Wholesale Druggists and Manufacturing Chemists, 91, 92, and 93, Bride street, Dublin.

WHOLESALE AGENTS:—Barclay and Sons; Newbery and Sons; S. Maw and Son; W. Edwards, London; Raimes and Co., Liverpool, Edinburgh, and York; Bewley, Evans and Co.; the Apothecaries Hall; Dr. Butler; George Oldham and Co., Dublin; Grattan and Co., Belfast.

Sold in bottles at 1s. & 2s. 6d each; also in Winchester Quarts for Dispensing.

Mr. Howard, Surgeon Dentist,

52 FLEET STREET,

has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble natural teeth as not to be distinguished from the original by the closest observer, they will never CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does NOT REQUIRE the EXTRACTION of ROOTS, or any PAINFUL OPERATION, and will support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication. Decayed teeth stopped and rendered sound and useful in mastication.—52 FLEET STREET. At home from Ten till Five.

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by one in., and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON 89 High Holborn, London.

N.B.—Aquariums, Fern Cases, and Glass Shades.

Riddell's Patent American

KITCHENERS cure Smoky Chimnies, save half the fuel usually consumed, yield a plentiful supply for hot water, require no brick work setting, are fully equipped with cooking utensils, and will roast, bake, boil, steam, fry, or broil better than any other kitchen range, and may be seen in operation daily at 155 Cheapside, London.

RIDDELL'S PATENT AMERICAN HEATING STOVES cure Smoky Chimnies, require no brick work setting, and are cheap, convenient, and very economical.

RIDDELL'S PATENT SLOW COMBUSTION STOVES for warming Churches, Entrance-halls, Schools, &c., will keep in full action from 12 to 30 hours without attention. A building of the cubic capacity of 20·000 feet may be thoroughly warmed at an expense for fuel of 5d. per day.

RIDDELL'S PATENT SLOW COMBUSTION BOILERS for warming Conservatories, Hot-houses, Warehouses, Churches, or Private Dwellings, by the CIRCULATION OF HOT-WATER will keep in full action 12 to 24 hours without attention, therefore dispensing entirely with watching or night work, require no brickwork setting, and are PERFECTLY SAFE.

Joseph Hadley Riddell, Stove and Boiler Manufacturer and Hot Water Fitter, 155 Cheapside, London, E.C.
Prospectuses free on application.

CLINICAL LECTURES.

MIDDLESEX HOSPITAL.

CLINICAL LECTURE
ON THE DISEASES OF WOMEN,

DELIVERED BY

DR. HALL DAVIS,

In the Theatre of the Middlesex Hospital.

GENTLEMEN,—In my last Lecture I dwelt upon the measures adopted for the palliation, or haply even the cure, by what may be considered but palliative agents, of prolapsus uteri and its varieties; I showed you the different instruments devised, the various pessaries constructed to serve divers purposes in either the alleviation of the distress, occasioned by this formidable complaint, or in its complete and permanent removal; moreover, I demonstrated the objects sought to be obtained in the use of these appliances, at the same time that I pointed out the good effected by some, the evil produced by others, the causes of failure in those which were unsuccessful, as well as the reasons of success in those which had fulfilled the purposes of their devisers.

I will now, somewhat briefly, allude to the surgical method of cure, which has for its principle a lessening of the capacity of the passage, the affording a cushion of support, the restoration of the normal condition of the parts, which has been made to deviate, either by rupture of the perinæum—more or less complete—or by a mere relaxation of the vagina and perinæum.

The accomplishment of the principle consists in making a kind of perineal section, in paring the edges of the fissure, denuding a certain extent of surface, if the uterine displacement result from ruptured perinæum, and then by means of the quill sutures, bringing these raw surfaces together, and maintaining them in apposition, till union is effected throughout. There are two kinds of sutures employed, the superficial and the deep; for the former, silver or iron wire is used, the edges are by means of it brought together, and are made fast *in situ* by merely twisting the wires upon themselves. The deep sutures must first be put in; they are usually of twine, but I see no reason why we should not use silver wire; indeed, from the clinical observations of Mr. Bryant, of Guy's Hospital, concerning the utility and inutility of the one or other kind of suture, I have arrived at the conclusion that the wires (silver), as proved by him, are decidedly advantageous and preferable. As we are passing the sutures from one to the opposite side, the thighs should be approximated, that the parts may lie in direct and complete apposition, and that there may be no undue straining upon the ligatures; on one side, the quill passes through the loops of the sutures; on the other, the suture is tied over the quill, so that we have a loop and a knot corresponding to each other, only that they lie on opposite sides. The number of sutures employed should be according to the nature of the case, three, four, or five, one form of lesion requiring more than another; however, it is well to have an equal number of superficial and deep wires. At the end of the third day, we should remove the deep, in order to obviate suppuration or sloughing; the superficial may be suffered to remain till the end of the week.

We must be cautious not to make too small a vagina. I have now before my mind a case, in which the perinæum had been sown up to such an extent, as to contract very much the vaginal orifice; the patient became *enceinte*, and when her full time had been accomplished, she fell into labour. I was in attendance, and seeing that a rupture of the perinæum was inevitable, and most probably at the cicatrix of the wound from the previous operation, I summoned the surgeon who had performed the operation, and to save his handy-work, he made two minute incisions obliquely, that is, radiating from the centre of the perinæum downwards and outwards; the child was then born; the cicatrix was found after the birth of the child not to have yielded; the incisions proved sufficient, as was evident by the fact of their remaining unlacerated.

These incisions saved the perinæum from a very extensive rupture, which might have even involved the sphincter.

Dr. Davis, at this part of his Lecture, showed an ovarian tumour, from a patient whom Mr. Moore had tapped some six months since, but in whom the operation had not been performed again, owing to the suspicion of cancerous deposit, in certain solid masses to be felt in the tumour, and to the existence of a cancerous diathesis. Mr. Moore had pronounced the case as one unfavourable for extirpation. The patient had measured round the waist 48½ inches.

The cyst was unilocular, with solid masses projecting from its walls into its cavity; it had been developed from the left ovary, the other, as well as the uterus, being perfectly healthy. Mr. Hulke had, by a careful microscopic examination, conducted after death, detected cancer cells in the cyst walls, and cancerous deposit had likewise occurred on the peritoneum. When the sac of an ovarian tumour is multilocular, the cells contain different materials; the turbid, gelatinous fluid is the pseudo-colloid of some authors. We may at times obtain in the cell contents the echinococcus hominis, and, even though the worm may not itself be discoverable at the period of our investigation, we may pronounce upon its having previously existed, if we are enabled to detect the hooklets by which it is characterised.

I will now take up the subject of those forms of posterior uterine displacement, which have received the names of Retroflexion and Retroversion; but to the first especially will I direct your attention.

In retroversion, no portion of the uterus is bent upon itself, but that condition exists, in which the fundus is tilted back into the hollow of the sacrum, and the os is thrown upwards at various angles with the pubis. In retroflexion, however, the case is otherwise, inasmuch as the cervix and os almost, if not completely preserve their natural position, their normal relationship with the neighbouring parts, the body and fundus being together bent upon the cervix in the manner of a retort. This is the distinction of the two affections; in some instances, we may observe both conditions co-existing.

Those who are the most frequent subjects of this affection, are women who have borne children, or in whom abortion has occurred; it is rare in virgins, still rarer as a congenital malformation. The period of life which predisposes to it is most assuredly that of child-bearing.

Now, the organ, be it observed, bends always at the *same* point, the seat of flexure is found in most, if not in all cases, at *one particular* spot, and for this constant condition there must be some valid reason. Professor Virchow has endeavoured to demonstrate this reason; he states the cause to be a thinning in that portion of the uterus where the cervix joins the body, and that here also the peritoneum forms a line of reflection, passing down to this point, having previously enveloped the *upper* par of the viscus, while it allows the *lower* portion to remain uncovered, which being connected with the bladder and vagina, is, comparatively speaking, made *fast* to them, while the body and fundus are easily moveable. Owing then to the weak-

ness in the cervix, of which we have just made mention, the fundus of the uterus sinks, becomes depressed and tilted backwards, if the posterior wall be the weak and yielding; or thrown forwards, if the anterior be that which has most lost its tone and healthy vigour. To the former conditions we apply the term—Retroversion, or Retroflexion, as the case may be; to the latter, Ante-version, or Ante-flexion, the latter being, however, a rare form of dislocation.

Causes.—First, relaxation of vaginal supports; secondly, weight of the fundus, an increase in the bulk and weight of either wall, determining the form of displacement; thirdly, the existence of fibrous tumours; fourthly, congestion of the body and fundus; fifthly, hypertrophy; sixthly, coagula in utero; seventhly, a deviation from the natural axis of the womb, coupled with straining at stool, so as to empty the bowels, which have been allowed to become constipated; eighthly, retention of urine, whereby the bladder being distended, forces back the upper part of the uterus, and thus gives the organ a tendency to this kind of displacement; ninthly, the lax condition of the parts that obtains in women after delivery and abortion.

That the married state predisposes to it, we cannot doubt, after the statistics advanced by West and Virchow:—of 110 cases cited by the former, 103 were married, and only 7 were single; indeed, the majority of the sufferers date the accession of the complaint to a period of delivery, or of miscarriage.

Three of Dr. West's cases out of 38 had fibrous tumour; 4 had ovarian tumour,—of these 4, one was unmarried, and dates the retroflexion from an unusually painful menstrual period.

The congenital form of the malady arises probably from a difference in the length of the ligaments, as well as a difference in the uterine development, as regards its separate halves.

We know full well, that some malformations of the uterus are attributable to its bifid development.

The SYMPTOMS may be so mild as hardly to be noticeable during life, and cases have occurred where they were wholly unperceived, and no suspicion of the disease entertained, till a post-mortem examination revealed the unnatural condition of the parts. In ordinary cases they are, however, as follows:—a sense of something falling down; menorrhagia; dysmenorrhœa; sterility, which is not an unfrequent effect; abortion, or a tendency to it, if conception have taken place; vomiting; frequent and painful micturition; nausea; painful defæcation; pain in the back, the loins, the sacrum, the groins, or down along the thighs, all of which latter symptoms are produced by pressure upon the sacral plexuses of nerves. You may remember, gentlemen, a case, which we had some time since in our wards, of partial paralysis of the legs dependent upon this pressure, and which was cured, as soon as the dislocated womb was reduced. Other symptoms are a sense of fulness and weight in the rectum; leucorrhœa, more or less profuse; congestion of the cervix and excoriation; the general health becomes deranged, the spirits depressed, the appetite bad, or entirely gone, the digestion very imperfect, the bowels always constipated, the entire system out of tone, and the nervous condition, termed the hysterical, superinduced. But these, gentlemen, are symptoms common to other affections, and not diagnostic of the malady, which is the subject of our consideration. Let us ask ourselves, therefore, what *are* the signs pathognomic? For their detection we must make a vaginal examination; we are thus enabled to find a tumour posteriorly, that the neck and os nearly, if not quite occupy their proper place in front of the tumour; while at the upper part of or the apex of the cone formed by the vagina, we meet the angle of flexure of the displaced uterus, and which, as we have before said, usually corresponds to the reflection of the peritoneum, to that point where there is a natural thinness of the uterine structure. By rectal examination, we can pass the finger above the tumour, above, in fact, the entire uterus. With these methods of exploration, we should not rest contented; we have indeed at our command to elucidate the case the uterine sound, which affords us, perhaps, the *most* reliable guide in our diagnosis, demonstrative proof of the true nature of the lesion, and enables us to distinguish it from the fibrous growths of this region, as also from ovarian tumours.

The sound should be admitted into the uterus up to the bulbous part of the instrument, which indicates a length of two inches and a half; this is supposing the uterus to be normal in every respect; if, however, there be retroflexion, the instrument will be stopped in the cervix by the angle of flexion; and, in order to enter the cavity of the womb, we must direct the point of it downwards and backwards; this done, by then turning it forwards, we cause the organ to right itself; reduction will have been then effected, and the tumour made to disappear.

In the use of this instrument we must most carefully avoid all violence and rough dealing; nor need there be any pain induced.

The great difficulty in the cure is the atrophy of the point at which yielding has taken place; the truth of this circumstance has been shown by Virchow and others.

The sequelæ of the disease are:—sterility, abortion, engorgement and chronic inflammation, hypertrophy of the uterus, enlargement of the ovaries, more especially of the left ovary, because the uterus, according to Rigby, is oftener tilted to that, rather than to the opposite side of the pelvis, and occasions irritation of the ovary lying therein; congestion of the os uteri and consequent abrasion, menorrhagia, retention of the menses, and, as a sequence, enlargement of the uterine cavity, dysmenorrhœa, leucorrhœa, a patulous condition of the os, so that the tip of the finger may be readily admitted; the edges of the os will be found red, and, if the case be one of retroflexion, there will be a shortening of the anterior lip; if, however, it be one of ante-flexion, the posterior lip will be the shorter.

Treatment.—Various, indeed, have been and still are the methods put into practice for the alleviation or cure of this complaint, and it would take us a long time to pass them all in review, so that I shall direct your attention to those which have either attracted most notice, or have been deemed most effectual. It occurred to Dr. Simpson that the organ in fault might not only be reduced, but also maintained, when reduced, in its proper position, by means of a metallic or ivory stem, passed into its cavity, there retained by a well-adapted support, and constantly worn by the patient. At first sight and theoretically, this would seem a most admirable contrivance, and the very instrument required to meet all the exigencies of the case, but experience shows us that very few women indeed can long wear it; neither is its use wholly free from danger; there have been some fatal cases put upon record.

I sometimes use a simple stem curved like a short catheter—three inches long. Once, and only once, I succeeded in effecting a cure with it. The curvature of this instrument had its concavity forwards, so as to give the uterus, when reduced, its natural inclination; the manner of introducing it was by passing the sound or a stilet into the hollow of the cylinder, inserting the stem with its concavity directed anteriorly; and leaving it in the uterus, the stilet was then withdrawn. Of course the uterus had been first brought into its right position. Only in one instance was this method successful; it was tried in others, but did not answer, as the presence of the instruments could not be tolerated; it was therefore speedily removed. I should mention that the cylinder was perforated to obviate retention of discharges.

Dr. Priestley has devised a pessary, which I have modified and used successfully in three cases. Dr. Fleetwood Churchill of Dublin has contrived a pessary to support the posterior wall of the uterus, when reduction of the organ has been effected. I have likewise had constructed a pessary to fulfil the same purpose.

Sometimes pessaries are made too long, and being an immense source of discomfort to the patient, hindering her walking or taking necessary exercise, preventing her all sitting, except upon the very edge of her seat, are not long tolerated.

There is sometimes encountered, coincident with the disease, a most distressing complication; I allude to exc

sive sensibility of the parts, a condition of hyperæsthesia at the very entrance of the vagina, and which in some instances is so great as to preclude the possibility of wearing an instrument, that must of necessity pass between these highly sensitive structures, in order to be made fast externally; sometimes, however, when no larger instrument can be borne, an ordinary-sized bougie may be worn without any discomfort; and when the parts are intolerant of even this, I employ two kinds of pessaries, one, the ring, which is passed up first, the other, the elastic ball, which, being introduced beneath and posterior to the former, supports it in the proper position.

M. Amussat has proposed and carried out a plan of exciting inflammation posteriorly, that is between the posterior walls of the cervix and vagina, so as to cause adhesion of the two inflamed surfaces and a greater degree of fixidity of the parts.

He has published two successful cases. This would, no doubt, be an admirable plan and worthy of adoption, could we only secure a bound to the inflammation; but, inasmuch as we have it not in our power to know how far the inflammatory process, once induced, may extend itself, we must regard the operation as hazardous; moreover, Dr. West has mentioned a case where accidental adhesion, consequent on inflammation, had occurred, yet without a cure being effected.

In our visit to the wards after lecture, we had the pleasure of seeing some very interesting cases.

The first was that of a married woman not pregnant, in whom vomiting has obstinately persisted for a space of three years, with only short intervals of relief; the entire range of the Pharmacopœia seemed almost to have been exhausted, as she passed through the hands of various medical men.

Notwithstanding this unnatural condition, which has continued for so long a period, the patient is not at all emaciated; on the contrary, she is actually fat, in apparently the best health, and enjoys the most excellent spirits; she is bright, cheerful, and animated. Dr. Davis had tried with her the oxalate of cerium, so highly recommended by Dr. Simpson, but with very trifling, if any, success; it was administered in half-grain doses. He ordered her to have instead the oxide of silver in half-grain doses three times daily.

In the second bed was a patient, mother of two children, who for over two years had seen very little of the menstrual discharge. Some months previously she observed a distinct tumour in the lower part of the abdomen, which had gradually and steadily grown larger. For the removal of this she had applied to different medical men, some of whom had pronounced it to be encysted dropsy of the ovary, and as such had treated it; finding the palliative measures fail, they had advised, as a "*dernier* resort," the excision of the diseased ovary, and in order that this operation should be performed, she had been admitted under the care of Dr. Hall Davis.

Immediately on laying his hand upon the abdomen and grasping the tumour, he thought he could detect the nature of it to be other than ovarian; it was very moveable in the abdomen from side to side, and seemed instinctive with life, judging from the "kicking sensation" communicated to his hand.

On applying the stethoscope, the "kicking sensation" was even more evident, and the beating of the fœtal heart at once declared the true state of the patient. She was pregnant.

Examination of the breasts showed them to be enlarged, having the peculiar knotty development characteristic of pregnancy. The areolæ were moist and greasy, the papillæ more evident than they are in the unimpregnated woman, and the vesiculoid arrangement, described by Dr. Routh in his recent Lettsomian lectures, might be detected; moreover, on squeezing the nipples, there exuded a clear watery discharge.

The true nature of the tumour was now perfectly evident.

ORIGINAL COMMUNICATIONS.

[*From the Case-Book of* BARNARD HOLT, ESQ., F.R.C.S., *Senior Surgeon to the Westminster Hospital, &c. &c.*]

UNUSUALLY LARGE SEROUS CYST SITUATED OVER THE INGUINAL CANAL AND PROTRUDING BENEATH POUPART'S LIGAMENT, WHICH HAD AN IMPULSE ON COUGHING, AND WAS RESONANT ON PERCUSSION.

The history of swellings in the inguinal canal or its neighbourhood are sufficiently interesting to be recorded, more especially when they vary in their nature so as to become difficult of accurate diagnosis. The following case embraces points of practical importance sufficient to warrant its publication:—

I was requested to meet Mr. Parrott, of Clapham, in consultation upon the above case. The gentleman in whom the tumour existed, first noticed it as a small swelling corresponding in the opening of the internal abdominal ring. It had succeeded to the exercise of riding on horseback, was unattended by pain, and not accompanied by any but trifling inconvenience in connection with the action of the intestines; but feeling alarmed at its presence, he consulted his family surgeon, who diagnosed it to be a hernia, and recommended him to keep quiet and wear a truss, which was accordingly provided for him, and which he wore for some months. The swelling, however, continued to increase, was resonant on percussion, had a strong impulse upon coughing, and his bowels were more torpid than natural. It was now ascertained that the swelling contained some amount of fluid, and as it gradually increased in size and fluctuation, was readily detected, his surgeon recommended a cautious opening to be made. He, however, went to Balham, and placed himself under the care of Mr. Parrott. In consequence of that gentleman not deeming the swelling so simple but that making an opening might be attended with some hazard, I was requested to see the patient. Upon examination, I found a large, irregular, and lobulated swelling, corresponding to the inguinal canal, containing fluid which was pressed downwards into the thigh, Poupart's ligament dividing the upper from the lower portion by a distinct line. The swelling was very resonant at its inner side, and more or less so all over the surface; there was a strong impulse on coughing, his bowels had not been relieved for two days, and he had been slightly sick, but neither his pulse nor his general aspect gave rise to the suspicion that any portion of the intestines was strangulated, although its functions might be temporarily impaired. Believing the case to be hernia, with probably a large quantity of fluid contained in the sac, attempts were made to return it without success. Ice was desired to be applied, the patient to be restricted to a slight diet, and that a dose of purgative medicine should be administered; it must be mentioned that there was but slight pain in the swelling. On the following day the bowels had been fairly relieved, but there was no alteration in the swelling. The patient subsequently came to London, where I had frequent opportunities of seeing him. The recumbent posture was for many days maintained, ice was continuously applied to the tumour, and still feeling assured that some intestine was protruding, he was subjected to the effects of chloroform, under which an attempt was made to return the swelling. This, however, like the previous ones, was futile. At this time I requested my friend, Mr. Arnott, to favour me with his opinion. The tumour had not altered in its character; it was still lobulated, and yielded a resonance upon percussion. Mr. Arnott examined the patient most carefully; and, although he could not determine the exact character of the swelling, yet he believed there was some protruding intestine, but he would

not express any opinion as to the character of the fluid. He acquiesced in the propriety of not further interfering, but that time should be allowed for the tumour to more clearly develop itself. The patient was kept to the sofa, a more liberal diet was prescribed, and the ice was discontinued; the swelling very slowly increased in size, and on Aug. 19, the integument being thinned at the outer and lower part, an exploratory opening was made with a very fine trochar, when some straw-coloured fluid escaped, similar to that which is usually met with in a cystic growth; about three-quarters of a pint of this was removed, when the canula was withdrawn. At this time, no further means were taken to remove the whole of the fluid, and in a few days it re-collected. A larger trochar was now thrust in, and the sac entirely emptied, the fluid was somewhat darker than it had been, and it contained numerous flakes of lymph; an injection of one part of iodine to four parts of water was now thrown in, which produced a burning sensation; it was permitted to remain for a few minutes and withdrawn, a bandage being applied over the sac. When the sac was empty a defined edge could be distinctly felt, and there was a considerable hollow corresponding to the swelling. The fluid soon re-collected, and the swelling was tapped a second time, the undiluted tincture of iodine being now injected, but beyond giving rise to rather more acute pain the proceeding was unattended by any advantage, the swelling speedily became as large as before, and it was determined to lay the part open, and procure granulations from the interior of the sac; at the end of September a free opening was made extending the length of the inguinal canal, and the finger having been introduced, the boundaries of the cyst were more accurately ascertained, the finger could be passed downwards beneath Pouparts ligament, and upwards behind the abdominal walls in front of the Psoas muscle; the colon had been pushed forwards and inwards, and gave rise to the resonance already described. For the first fortnight the case progressed favourably, suppuration was fairly established, the pus being of a healthy kind, but he now complained of the most severe pain, extending along the course of the left sciatic nerve; the pain was so intense as to compel him to cry out. Opiates were administered internally, and chloroform and opium together with blisters, &c., applied externally, but with little alleviation to his suffering. He now complained of pain in the hip-joint of the affected side, and could not bear the limb to be in the least degree moved. A weight was applied to the extremity of the limb which, by preventing approximation of surfaces, gave some relief; he continued more or less in the same state for two months, when the character of the discharge suddenly altered, becoming bloody, offensive, and dark, and pressure upon the buttock caused it to escape from the opening in the groin; a probe passed freely into the pelvis in the direction of the sciatic foramen. From this time he never rallied and gradually sank. No post-mortem was obtained. The features of interest in this case were many: Firstly, with regard to the resemblance to a hernia. The swelling had succeeded to rough and unaccustomed exercise, it was situated in the course of the inguinal canal, it communicated an impulse on coughing, and was resonant on percussion. On the other hand, it could not be returned within the abdomen, and had not escaped through the external abdominal ring, but this, as is well known to all practical surgeons, was no evidence that the case was not one of hernia.

The swelling gradually increased in size, and, although it was at first confined to the space allotted to the inguinal canal, it now gravitated beneath Poupart's ligament without passing into the scrotum. No doubt this was a perplexing point, but taken alone it did not assist the diagnosis, inasmuch as the swelling might have arisen from a direct hernia, bursting through the abdominal walls between the internal oblique and transversalis muscles, and so have made its way under Poupart's ligament. Taking the whole circumstances into consideration, they were, I submit, sufficient to warrant the belief in the existence of a hernia; but whether that hernia was connected with abscess, or an undue collection of serous fluid, was only determined by the puncture that was subsequently made. Mr. Paget, in his Pathological Lectures, says, "such cysts may be formed anywhere," but he gives no other examples than those which are met with in the neck and mammæ. The symptoms which disclosed themselves during the progress of the case, and the subsequent escape of the fluid into the buttock, together with the freedom with which a probe could be passed into the pelvis towards the sciatic notch, were sufficient to make tolerably clear the pain the patient experienced in the course of the sciatic nerve. I have no doubt the fluid made such pressure upon the nerve previous to its escaping into the buttock, as to account for the acute sciatica. So far as I know, the case is unique and worthy of record.

ON THE USE OF MERCURY IN SOME AFFECTIONS.

By DR. G. DE GORREQUER GRIFFITH.

As this subject has been recently discussed at the Harveian Society, and the interest excited by Dr. Drysdale's paper has not yet died out, I beg the insertion of the following in your columns, merely to give *afresh* the opinions of great men, as to the advisability of the use of this mineral:—

Dr. Gooch, in his work on Diseases of Women, writes thus, when writing of the treatment of "Irritable Uterus:"—"Three to five grains of blue pill or compound calomel pill mixed with five grains of extract of henbane taken every night, or every other night for many weeks, have sometimes, without affecting the gums, occasioned a very regular action of the bowels; and during its influence the periodical aggravations of pain have not recurred, and the permanent pain has diminished, and at length ceased altogether. Whilst the mercury has had this favourable influence over the local disease it has occasioned no material injury to the constitution. This has been the effect chiefly, when the health has not been much reduced, and the disease has not lasted very long:"—

In Case I. recorded by him in the volume to which we have above referred, bleeding having been adopted without abatement of the pain or the disturbance of the circulation, the patient took five grains of extract of henbane and one of calomel twice daily, and "in about ten days her gums became sore and continued so for several weeks immediately the disturbance of the circulation ceased the pulse was slow and soft, and never resumed its former excitement, the pain likewise became considerably less, and the paroxysms came on at longer intervals." The patient recovered perfectly. Dr. Gooch in this manner successfully treated the *chronic* forms of irritable uterus, while Mr. Fernandez as successfully used for the acute forms the same mineral.

On the use of mercury in typhoid fever Dr. Wood, in his Treatise on the Practice of Medicine, writes at page 345, vol. I.:—"Very often after the seventh or ninth day a condition of things supervenes, which must be met by the use of mercury; there is a general deficiency of secretion the tongue is dryish, the skin dry, and the urine scanty the pulse, though perhaps more frequent, is neither so full nor so strong as at first; some degree of delirium or an increase of stupor often supervenes, and the abdomen becomes tympanitic. Without any diminution in the violence of the disease, a close examination will show that the energy of the vital actions has abated. Under these circumstances I know of no remedy so effectual as mercury given so as *very slightly* to affect the gums.

"It is indicated by the general failure of the secretions and the general languor of the vital functions. It is not improbable that mercury may serve in some degree to arrest the progress of disease in the glands of Peyer, and to promote resolution of the inflamed patches; but the

impression should be made in the mildest way. Large doses of calomel are out of the question. I usually prefer minute doses of the blue mass, given at short intervals, as for example a grain every two hours until the mouth is affected.

"Minute doses of calomel, as the $\frac{1}{4}$ or $\frac{1}{6}$ of a grain may be substituted for the blue mass, if preferred by the practitioner. The mercurial should be continued until the gums are slightly touched, and then either diminished gradually or omitted.

"Under its influence the tongue not unfrequently becomes moist, the skin relaxed, and all the other symptoms ameliorated, and the patient recovers without further treatment. Severe ptyalism should be scrupulously avoided."

Such is the advice of Dr. Wood, Physician to the Pensylvania Hospital, and President of the College of Physicians of Philadelphia.

The following as bearing upon the fact, which I advanced at the debate upon Dr. Drysdale's paper,—that the unalloyed poison of syphilis is alone sufficient for producing many of, if not all, those untoward consequences usually ascribed to the mercurio-syphilitic—I quote from the book of Dr. Daniell, entitled "Sketches of the Medical Topography and Native Diseases of the Gulph of Guinea":—

"Syphilis is, perhaps, the most frequent and fatal of maladies, to which the male inhabitants are liable, and predominates more among them than among females; many are cut off very early in life *from want of* the necessary remedial applications, and it is not uncommon to meet with cases which have continued nearly two-thirds of the *patient's existence.*

"The worst forms of syphilis which have come under my notice have been the foul and malignant phagedænic ulcers, that indiscriminately attack both sexes:—

"Nodes, cutaneous eruptions, and indeed all the sequelæ of syphilis in multiform varieties are extremely prevalent, and not unfrequently resist the most energetic and judicious treatment of European Surgeons."

The native means of cure by charms and such like, "afford but a transitory hope of any other than a fatal termination."

To this no doubt many surgeons can subscribe; and abundant proofs might be gathered from the experience of practitioners, as well as from the records of our Lock Hospitals.

HOSPITAL REPORTS.

UNIVERSITY COLLEGE HOSPITAL.

OPERATIONS BY MR. ERICHSEN.

We are glad to say that the cases operated on by Mr. Erichsen, and which we reported in our last number, are in a most favourable condition, and are rapidly advancing to health. The operations were two: one was a case of amputation of the breast, and of a cancerous tumour developed in it; the other was the lateral operation in a child for the removal of a lithic acid calculus.

To-day (Wednesday, Jan. 13), Mr. Erichsen was engaged with *five* cases:—

The *first* was a young man, an Army Hospital mate, who some time previously had been a patient for syphilitic necrosis of the bones of the calvarium, which had come away in the manner usual in such cases; at that time the pulsations of the brain could be distinctly perceived, distinctly as we can at times detect it in the young child before the fontanelles have become ossified; now, however, the cavity that existed has been filled in, the exfoliated bones have been replaced by a kind of fibrous tissue, and consequently the brain pulsation, so evident before, can now no longer be appreciated.

This patient had likewise suffered from extensive disease, syphilitic necrosis—of the right clavicle, portions of which had been removed by Mr. Erichsen on a former occasion. At present there were only traces of the wound, and the patient had complete use of his arm. The operation to-day was necessitated by a portion of the sternum having become necrosed; and Mr. Erichsen having first probed accurately the wound, in order to define the extent of the dead bone, and having made the wound in the soft parts sufficiently large to admit the osteotrite, proceeded by means of it to bore away the diseased bone in the same manner as dentists do decayed teeth. No chloroform was administered.

Mr. Erichsen, in instances similar to the present, prefers the use of the osteotrite, such a one as has been designed by Mr. Marshall; it is not so likely to slip as the gouge; "it will be found a very useful instrument, clearing away softened bone without risk to the surrounding healthy structures;" it pulverises rather than chips off the bone we wish to remove.

The operator dwelt upon the specially interesting features of this patient's history, which were as follows:—He had never taken any mercury; this the man knows for a positive fact, because of his position as hospital mate he was able to tell what medicines he was ordered and what medicines he took; and yet, though he has received into his system no mercury whatever, though there be no mercurio-syphilitic poison, we find him the subject of a severe constitutional tertiary form of the venereal disease. This, said Mr. Erichsen, is one of those cases to which I have long been accustomed to direct your attention; and at this moment when the subject of the administration of mercury in syphilis is a strongly-contested point, it claims your most particular interest. You have often heard me say that no mercury is needed in syphilis to produce those worst consequences which come under our notice, and which are stated by some to be the sequences only of an amalgamated taint—of the mercurial and syphilitic poisons, and this case admirably illustrates my words; not only in this, but in many other instances have I seen the bones diseased, the bones removed by disease, ecthyma and rupia rapidly develop themselves, and the patient or patients to have taken not a grain of the mineral.

CASE II was that of a stoutly-built young countryman, aged about twenty-one, who had oblique inguinal hernia of the right side.

Mr. Erichsen stated that he was induced to prefer Wütz er's operation for the radical cure of hernia—first, because in a large number of instances it fulfilled the purposes for which it had been devised, viz., the blocking-up of the inguinal canal, and thereby the prevention of the recurrence of the rupture; and, secondly, because of the greater safety afforded by this method, when compared with other operations planned also for a radical cure.

The *rationale* of operative proceedings for permanent removal of this affection consists in, by the excitation of a certain amount of inflammation in the body of the sac, or in its neck, the agglutination of the tissues, and the consequent obliteration of the canal, through which the descent takes place; or in a mere invagination of the integument, whereby the hernial channel is blocked up.

"If," says Mr. Erichsen, in the last edition of his 'Science and Art of Surgery,' "the accomplishment of these conditions would always prevent the recurrence of the rupture, the radical cure might frequently be undertaken. But it is impossible to look upon the agglutination of the walls of the sac, or the closure of the abdominal aperture as the sole conditions required. To accomplish the radical cure it would be necessary in many cases to effect changes in the shape and connections of the abdominal contents, to alter the size of the abdominal cavity, and, indeed, to modify in various ways many conditions independent of those immediately connected with the hernial protrusion."

Wütz er's operation has for its objects the amalgamation of the walls of the sac by the peritonitis induced, and the plugging of, not the external inguinal ring alone, but also of the inguinal canal itself, by the portion of scrotum which is invaginated, and these are effected with a far less risk o

danger to our patient than any other of those operations put in force for the radical cure.

"His (Wützer's) plan of treatment," we again quote from the 'Science and Art of Surgery,' "consists in introducing a plug of the scrotum into the inguinal canal, and fixing it there by exciting adhesive inflammation in the neck of the sac.

The details of the operation are as follows:—The patient lying on his back, and the hernia being reduced, the surgeon pushes his index-finger up the inguinal canal as high as the internal ring, carrying before it a cone of the scrotal tissues; a box-wood hollow cylinder, about four inches long, well oiled, is then pushed up as the finger is withdrawn, so as to occupy its place in the inguinal canal.

Along the interior of this cylinder a flexible, gilt-steel needle, fixed in a moveable handle, is then pushed, so as to traverse the invaginated scrotum, the hernial sac, and the anterior abdominal wall, through which its point is caused to protrude. A concave box-wood case is then passed over the projecting point of the needle, and fixed by the other end by a screw apparatus to the cylinder, so as to compress the inclosed tissues.

The apparatus so fixed is left *in situ* for six or eight days, when, some discharge being established, it is withdrawn, and the invaginated scrotal plug, supported by lint, introduced up its interior.

The patient is kept quiet for a fortnight longer, when he is allowed to move about, wearing a light truss for three or four months.

The dangers to be apprehended in, and the objections which have been urged against, the performance of this operation, are, that we may be unable to set a limit to the amount of inflammation excited, and, that not always securing the desired adhesion, the bowel may again descend, press upon the invaginated scrotum, slip down behind it, and come to be in a condition almost, if not altogether, as bad as heretofore; the good effects of the superstructure we had raised being wholly nullified.

A selection of cases must be made; we should not adopt the operation without due consideration of the indications and the contra-indications. We should put it into execution, if our patient be in the possession of good health, if he belong to the labouring class, and especially if his labours be very heavy.

CASE III was an old soldier, aged seventy-six, of spare habit; he had been a patient of Mr. Cooper, Surgeon to the Bloomsbury Dispensary, by whom he was recommended to place himself under the care of Mr. Erichsen. The disease demanding the operation was a cancerous deposit at the angle of junction of the corona glandis, and the prepuce.

The history the man gave was to the effect, that some time since he noticed a tubercle at the site already mentioned; that it was attended with hardness, and at length took an ulcerative action, and exuded a peculiar discharge, such as we know the cancer ulcer alone throws out.

In this case, the operator considered the steps about to be taken fully justifiable, even in such an old patient, inasmuch as the health was good, there being no cancerous cachexia; the disease wholly localised, the glands at the root of the penis, in the groin, and elsewhere, being in no way involved; the operation was unattended with danger; the probabilities of no return of the disease were very much in favour of the patient. In this last respect—namely, in the likelihood of there being no recurrence of the disease, this operation is, far before all others, adopted for the removal of malignant deposits in any other region of the body. No doubt there are cases in which the glands in connection with the diseased part being implicated, there will be a return of the complaint, in either the cicatrix of the wound, or in the involved glands; yet, even under these circumstances, it is the duty of the surgeon to remove an *urgent, present*, and loathsome condition, to *ameliorate* actual suffering, and to put his patient in a state of comparative ease and comfort, or at least in one of immunity from discomfort.

This is a point not sufficiently inculcated by surgeon and, therefore, would I the more earnestly press it upo your attention; if you cannot cure, even if there be certainty of a recurrence, operate and mitigate the *preser* distress; the more so would I set it before you for you most careful consideration, because the operation can at th present day, by means of chloroform, be rendered com pletely painless.

In a number of cases the disease may not return for si eight, or even more years; in a large number of instanc there may be no return of deposit whatever, the affectio having been once removed.

The operation is simple, can be quickly performed, attended with no difficulties, and almost entirely devoid any danger. We must draw the skin, not as we are wo to do in amputation of a limb, backwards, that is, aw from the line of our incision, but well forwards, so as n to leave too much of the tegumentary tissue, which woul be a constant source of subsequent annoyance, by its co tinually coming down over the orifice, and so hinderi micturition; or lest, owing to the great retractility of th corpora cavernosa, it would overlap the face of the stum and offer a barrier to our search after the divided vessel or, again, lest it should, by afterwards puckering, make th patient uncomfortable Our incision must be made su ficiently far back toward the root of the organ, in order get well free of the disease, and yet we must avoid th danger to be incurred, by cutting too close upon the pube underneath which the remains of the penis may retrac and become buried in the perinæum, entailing upon th operation a disagreeable tediousness and complication fro the difficulty, which will be thus experienced in tying th vessels.

This accident may, however, be obviated by securing we the penis behind our incision, both with the aid of a ta ligature, and of the fingers of an assistant; but, if th accident do occur, we must then pass into the urethra large-sized female catheter, at the same time that exercise firm compression upon the bleeding surface, means of a T-shaped bandage.

Having drawn the skin well forward, and tightly ti a tape ligature around the penis, which he then gave in the care of an assistant, that he should compress it, for th purpose before mentioned, Mr. Erichsen, placing the ed of the bistoury against the lower surface of the orga swept it round the latter, and thus, with one stroke, co pleted the operation. Five or six vessels required to tied, the two arteries of the corpora cavernosa, one in ea corpus, the dorsales penis, and the artery of the septu but, as the penis had not retracted itself under the pu arch, there was no difficulty experienced in their deligati

On making a vertical section of the part amputated, the was seen a hard, cancerous deposit, about the size o small split bean, occupying a point in the groove of corona glandis, but more particularly encroaching upon t prepuce, extending itself likewise into the corpora cav nosa, but not into the corpus spongiosum; the tissue little posterior to this mass, were apparently quite free fr any infiltration.

There was no catheter passed after the vessels had b ligatured, there being no indication for its use.

(To be continued.)

DISPENSARY FOR DISEASES OF THE THROA

(Under the care of Dr. MORELL MACKENZIE.)

The following cases illustrate very remarkably the va of the internal application of galvanism in functio diseases of the larynx:—

CASE 1.—*Aphonia of two years' and-a-half duration, a case of phthisis, cured by the application of galvanism the vocal cords.*—Margaret H., æt. thirty-nine, applied at Dispensary in October, 1863, on account of loss of vo which had existed since March, 1861. She was tall, p and thin, with a heated flush in both cheeks. There crepitation at the apex of the left lung, and she had sev times spat up a small quantity of blood.

She stated that she had never been at all hysterical,

she never manifested any signs of that disease whilst she was under observation.

The laryngoscope showed that the vocal cords scarcely moved at all from the sides of the larynx, when the most forcible attempts at phonation were made, only a feeble whisper could be produced.

Oct. 24.—Galvanism applied to the vocal cords succeeded in restoring the voice, but it was lost before she arrived home (in the Euston Road).

Oct. 31.—A strong electric current was passed through the vocal cords, and this time the voice remained permanent.

CASE 2.—*Aphonia of nine years' standing: the voice restored (whether permanently or only temporarily is not known), after one application of galvanism to the vocal cords.*—Rebecca D., æt. thirty-six, applied at the Dispensary in November, 1863. She states that her voice has always been weak since she had the measles when six years old, and that she occasionally lost it suddenly after that time. In 1854, a week after a miscarriage, she lost her voice, and though for a few weeks she was able to speak gruffly, in the early part of 1855 she lost it completely, and since then has never spoken above a whisper; "she has suffered many things of many doctors." In 1848 she was an in-patient in the Brompton Hospital, and she then had loss of voice; after that she attended at several dispensaries. In 1860 she was an out-patient at University College Hospital, and in the spring of 1862 she was attending at the Middlesex Hospital. She has had blisters and leeches applied externally, "burning *stuff*" put down the throat, and taken an immense quantity of physic. She stated that she used to be hysterical, but for the last two years she had never been so.

After two or three strong shocks had been applied internally, the patient was able to speak in a fairly strong voice. She remained about half an hour, during which time the voice did not lose its power. It is not known whether the patient's voice remained, or whether it was again lost: the latter is the more probable. The patient* has not again appeared at the Dispensary.

REVIEW OF BOOKS.

The Diet of Infancy and Childhood. By S. Barker, M.D. Pp. 70. London: Hardwicke, 1864.

The object of this pamphlet, as stated by the author, is to disseminate among the public, and especially among females, a species of knowledge in which many are too often lamentably deficient, namely, the proper method of nourishing infants and children. The accusation of ignorance on this point, is, we believe, a just one, and multitudes of young women who are carefully instructed in a variety of accomplishments to render them attractive in society, are left wholly uninformed in the duties which they ought to execute in the nourishment of their offspring, in case they should become wives and mothers. Without wishing our young ladies to be profoundly versed in physiology or chemistry, we cannot but regret that the fundamental laws of life should be to their minds as a sealed book, and that on the subject of food, the most erroneous notions should still prevail, and the most absurd and even injurious practices should still be followed. Much of the contents of this little work, judicious as the remarks are throughout, is unnecessary to the medical practitioner, because he is already well acquainted with the physiological and chemical laws relating to the diet of infancy; but to the majority of readers, most of the observations will present the appearance of novelty. It is to be hoped that many ladies will read them and act upon the precepts which they inculcate, by which means a great amount of sickness and suffering will be averted both from infants and mothers. The condemnation of the practice of fashionable ladies omitting to suckle their own children is strongly but justly expressed, and the adoption of different kinds of food in proportion to the advancing age of the child, is explained in language which proves Dr. Barker to be fully acquainted, both theoretically and practically, with all the details of his subject.

* Those who are anxious to investigate this remarkable case may do so by making inquiries at 9 Upper Ogle street, Marylebone.

THE LIFE OF HIPPOCRATES.

By the Rev. SAMUEL HAUGHTON, M.D., Fellow of Trinity College, Dublin.

Hippocrates was born in the island of Coos in the Ægean Sea, which was famous for its wines and silks, and also as the birthplace of the painter Apelles, and of the poet Philetas. His father was Heraclides, a physician of the race of Esculapiusa, and his mother was Phænarete, a descendant of Hercules. He was born 460 B.C., and was a contemporary of Socrates and Plato, being junior to the one and senior to the other; he was taught the art of medicine by his father and by Herodicus, who wrote a book on "Gymnastic Medicine."

Coos was celebrated for its school of medicine, which was rivalled only by that of Cnidos, on the neighbouring mainland. The School of Coos appears to have cultivated Prognostics, and that of Cnidos Diagnostics. That the rivalry between these schools was very great may be inferred from some passages in Hippocrates' "Treatise on the Diet suitable to Acute Diseases," and especially from the story currently believed in after times that Hippocrates actually burned with his own hand the library of Cnidos—a statement about as credible as that a professor in Dr. Steevens' Hospital had burned the library of the College of Surgeons.

Having completed his education at Coos, he went to the island of Thasos, where he practised his profession, and also in Abdera, Larissa, Melibœa, and Cyzicus. At Abdera he made the acquaintance and secured the permanent friendship of the philosopher Democritus, who was a native of that city. During his residence in Thessaly, he collected the materials for his two books of Epidemics, which will remain during all time as the model for clinical lecturers to imitate. He seems also to haue visited at this period of his life Libya, Asia Minor, and Scythia, and to have collected the information recorded in his treatise on "Airs, Waters, and Localities."

Some writers have inferred from the cases recorded in the Epidemics that he was not a successful practitioner; but it appears to me that it would be more correct to infer that he recorded faithfully all his experience, and that, contrary to modern practice, his unsuccessful as well as his successful cases are registered in his tables.

Be this as it may, it is certain that he ultimately returned to Coos, and devoted the remainder of his long and useful life to the teaching of medicine, by which he earned his livelihood, and to the composition of the books which have immortalized his name.

In extreme old age he revisited Greece, and died 357 B.C., at the age of 103 years, and was buried between Gyrtona and Larissa.

It appears nearly certain that Hippocrates never visited Athens during his travels, and that he had never heard of the famous plague of that city recorded by Thucydides, although he was thirty years of age at the time. From this circumstance it would appear that this plague principally concerned the Attic Greeks, and that Ionians, like Hippocrates, knew and cared little about it. The case of the sick woman in the "Liar's Market," recorded in the Epidemics, has been supposed by some critics to have occurred in Athens, but no doubt there were liars and liars' markets in other cities besides Athens; just as there are markets called the "Louse Market" in many cities of Russia, besides the famous one in Moscow.—'Dublin Medical Press.'

THE MEDICAL CIRCULAR.

MR. SYME ON MEDICAL EDUCATION.

The position of Mr. Syme as Professor of Clinical Surgery in the University of Edinburgh, and as an influential member of the General Medical Council, entitles his opinions to very great respect and attention, but we must not, solely on that account, neglect to notice the narrow views on which they are based, and the erroneous conclusions to which they tend.

One primary error in Mr. Syme's reasoning springs from the circumstance that his sphere of vision seems to embrace only the University of Edinburgh, or, at any rate, that University together with those of Glasgow and Aberdeen, and also that he regards these institutions as almost the only real Medical educational bodies in the British Empire. "The English Universities," he remarks, in a pamphlet he has just published, entitled 'Observations on the Present State of Medical Education, with Suggestions for its Improvement,' "are not known as Medical schools, and the value of their degrees depends chiefly upon the evidence of classical accomplishment which they afford, while the Universities of Scotland are the great Medical seminaries of the country, with teachers in every department appointed by public authority, with large hospitals, and with every other requisite for practical study. The cases of these institutions are, therefore, wholly different, the object of the former being to prepare a few fashionable physicians for metropolitan practice, and that of the latter to provide efficient Medical assistance for the general wants of the community."

Now, admitting that the only objects of the Medical department of the English Universities is to "prepare a few fashionable physicians for metropolitan practice," and admitting (although we think it very doubtful) another statement made in the same pamphlet, that "the Universities of Edinburgh, Glasgow, and Aberdeen, at present educate more Medical students than all the schools in London put together," yet we may ask is there no School of Medicine in Ireland, and are all our Metropolitan Hospitals, with their rich endowments, their efficient staffs of teachers, and their multitudinous appliances, to pale into insignificance before the splendour of the three Scotch Universities? Mr. Syme evidently thinks that these latter are incomparably superior, as Schools of Medicine, to all the English and Irish Universities, and all the Hospital and other Medical schools throughout the British dominions.

If Mr. Syme had entitled his pamphlet 'Observations on the Present State of Medical Education in the University of Edinburgh,' the title would have been infinitely more appropriate, and his remarks would have been rendered intelligible; for some of his statements are quite inapplicable to any other Medical educational establishment, and many of them, we apprehend, would be combated by his own colleagues. His remarks, for instance, upon the superfluity of the Chair of General Pathology in the Edinburgh University, are entirely of a local character, and probably have a personal bearing upon Dr. Henderson, the present occupier of that Chair, who is known to advocate homœopathic views in practice, and who is, perhaps, aimed at in the suggestion that if any lecturer should "allow an unruly hobby to carry him away from the field of practical utility into the regions of unprofitable speculation, or, still worse, should teach doctrines not conducive to sound practice," then Mr. Syme would "endeavour to correct the evil of his ways by remonstrance, by censure, *or, if necessary, by deposition.*"

We are not quite sure that the Homœopathic Professor of Pathology is the only lecturer whose "evil ways" Mr. Syme would endeavour to correct by these mild expedients, for in a passage immediately preceding that which we have just quoted, he tells us that he would treat in the same way those lecturers "who loaded the memories of their pupils with undigested or undigestible details." As we are informed at page 7 of the pamphlet, that the Professor of Practical Medicine has placed in the hands of his pupils a printed list of no fewer than eight hundred fevers (reduced in a foot-note by Mr. Syme to five or six hundred), and as Mr. Syme states that he himself is hardly able to digest even three—namely, synochus, synocha, and typhus, it is very likely that Dr. Laycock would also be subject "to remonstrance, or censure, or, if necessary, deposition.' Nay, we are not sure that the Professors of Chemistry and of Botany would not alike be censured and deposed, for Mr. Syme makes us acquainted with the fact, that Chemistry was once a science which anyone might comprehend, who possessed an ordinary degree of intelligence, but now none but persons of superhuman intellect can master its details; and as to Botany, it seems to have changed its character altogether, for Mr. Syme himself examined four students in Botany on one occasion, and found them totally ignorant of the science; but on the very next day, the same gentlemen appealed to the Professor of Botany, and passed a triumphant examination! It is quite clear, from this fact, that Mr. Syme knows much more about Botany than his colleague, the botanical Professor.

We are not quite certain that Dr. Hughes Bennett would altogether escape censure, even if he escaped deposition for the histological Professor is evidently slyly aimed at among the modern anatomists, who "by means of their microscopes have opened up an entirely new field of inquiry, and have thus extended their researches far beyond what the wildest imaginations could have anticipated.

If Mr. Syme, therefore, could have his own way, and possessed the power of remonstrating with, censuring, or if necessary, deposing, the refractory Professors of the University of Edinburgh, he might cut off "at one fell swoop" like Macduff's wife and children, the Lecturers on Pathology, Practice of Medicine, Chemistry, Botany, and the Institutes of Medicine; until, like the Kilkenny cats, who left nothing but their tails behind them, they would leave almost nothing but the Professor of Clinical Surgery, who would then constitute the University in himself. The minds of the students would thus be relieved of the neces

sity of acquiring an immense mass of useless details, and one sole examiner in the different departments of Medical and Surgical Science would reduce learning to its proper dimensions. Anatomy would return to its due limits, such as existed before the microscope lent wings to the wildness of the imagination of histologists; Chemistry, reduced to its ancient simplicity, would be content with the doctrines of the Archæus and of Phlogiston; and Botany, discarding the use of the microscope, and of an indefinite and unintelligible terminology, would become what it ought to be, in Mr. Syme's eyes—namely, "a most agreeable recreation," instead of what it is now, "one of the most oppressive weights on a student's mind." In Medicine and Surgery, the same care would, of course, be taken to prune away all useless redundancies; the five, or six, or eight hundred kinds of fevers would again shrink into two, or at most, three, and no new surgical operations would be tolerated, except by express sanction and permission.

Such might be the beginning of Medical Educational Reform at the University of Edinburgh, which, as being the chief, if not the only seat of learning, where Medicine is properly taught to the Anglo-Saxon race, or, indeed, to the *Universe*, would, of course, lead the van in a great and *essential improvement* in Medical education and examination throughout the world. When these essential changes have been effected in the method of teaching Medicine in the modern Athens, it will then be time for the other and inferior Medical bodies to set their houses in order, and to follow the example thus placed before them.

SUMMARY OF THE WEEK.

THE ACCOUCHEMENT OF THE PRINCESS OF WALES.

The curiosity naturally excited by this event has been stimulated rather than gratified by the accounts published in the pages of some of our contemporaries, but the fact is that the Medical attendants of the Court are forbidden by etiquette to give any information as to the condition of their Royal patients, beyond that which appears in the official bulletins. All the particulars published by our Medical contemporaries are little more than amplifications of the statement we made on the subject last week, unless indeed it be considered important for the public to know that the Royal infant is pretty, and very like his father, and that he is to have a wet-nurse, whose name is Mrs. Connor. Whether Mrs. Connor is a native of the sister *island*, or whether she is an Englishwoman of Hibernian *extraction*, we have not been able to ascertain; but it is certain that she is a married woman, of irreproachable character, and we are further informed that "she possesses the requisite physical qualities." One statement made in the 'Times,' that the infant, which is said to be one of seven months, weighed *nine pounds*, has astonished some of our Medical contemporaries, and has called forth from them a positive assertion that the Royal infant has never been weighed at all. Notwithstanding this solemn assurance, the statement of the 'Times' is repeated without any explanation or qualification in the 'Observer' of Sunday last; and we can only state, for the benefit of those who may not be practically acquainted with Medico-legal investigations, that it is very rare even for a child of the full period to weigh so much as nine pounds, and that the average weight is from six to eight. Supposing the Royal infant to be a seven months' child, the weight would probably be from four to six pounds.

THE NEW PRESIDENT OF THE MEDICAL COUNCIL.

On Wednesday last the Medical Council met at their rooms in Soho Square, for the purpose of electing a President in place of Mr. Green, and after a considerable discussion, Dr. Burrows was appointed. The discussion turned upon several points, a proposition having been started that a non-professional person, having a seat in Parliament, would be preferable to a Medical man, and some of the members of the Council supporting Dr. Stokes as the future President. Both propositions were over-ruled, and for very manifest reasons, as it was felt that the President ought to be a Medical man, and that he ought to be resident in London. The Medical Council will meet for the dispatch of business on the 25th of April, and it is said that reporters will be admitted to the meetings.

THE VACANT EXAMINERSHIP AT THE COLLEGE OF SURGEONS

The lucrative post of Examiner at the College of Surgeons will shortly be filled up. There are three gentlemen who stand nearest in point of seniority for the vacant office, namely, Mr. Gulliver, Mr. Partridge, and Mr. Hilton. It is said that Mr. Gulliver has declined to have himself put in nomination, and that the choice of the Council will fall on Mr. Hilton. If such should be the case, a vacancy will be caused in the Examinership in Surgery in the University of London, which Mr. Hilton at present holds, but which he will be obliged to vacate.

THE TOWNLEY CASE.

An entirely new light has been thrown upon this case by the publication, on the part of Sir George Grey, of all the correspondence which has taken place upon the subject. A number of vague rumours have been floating about as to the means by which the respite was obtained, and it was generally believed that the judge who tried the case, the governor and the surgeon of the gaol, and the Commissioners in Lunacy, were all convinced of the prisoner's insanity; but it turns out that such was not the truth. In fact most of the parties seem to have been puzzled and bewildered as to the real state of the matter, and Mr. Gisborne, the surgeon of the gaol, who gave evidence at the trial in favour of the prisoner's insanity, has now written a letter expressing his great doubts upon the subject, and the governor of the gaol has also written a letter declaring that he never considered Townley mad at all. Mr. Gisborne has been pretty sharply criticised for the varying opinions which it appears he has given at different times; but it is only fair to observe that the acute judge who tried the case appears to have been equally perplexed. Baron Martin actually wrote to Sir George Grey after the trial, recommending a further inquiry as to the prisoner's state of mind, but on

being pressed for his reasons in so doing, frankly though cautiously admitted that he had formed no decided opinion upon the point himself. Thereupon Sir George Grey requested the Commissioners in Lunacy to investigate the case, and three of their number accordingly went to Derby, and had a long interview with the prisoner, besides examining a great number of witnesses. The result of their inquiry was that although they could not consider him to be of sound mind, yet that "as he was in the same mental state as when he committed the murder and underwent his trial, they thought that, applying the law as laid down by Baron Martin to the case, he was justly convicted." The perplexity of all parties is really remarkable; Mr. Baron Martin sentences the man to death, but after the sentence he recommends a further inquiry to be made as to his mental condition, although he (Baron Martin) had formed no decided opinion on the point; the Commissioners in Lunacy do not consider him to be of sound mind, but still they think that Baron Martin was right in his summing-up and in his subsequent sentence; Mr. Gisborne, the surgeon of the gaol, is in doubt as to Townley's state of mind until nearly the end of the trial, when he pronounces him insane, and the governor of the gaol merely declares that he was in the same state of mind just before the trial as he was when he was first sent to prison, his meaning being that Townley was never mad. The real cause of Townley's respite, was the signing of a certificate under a particular Act of Parliament, by two justices of the peace and two medical men, to the effect that the prisoner was insane, and it seems that this certificate over-rode the authority of Sir George Grey, the sentence of the judge, the report of the Lunacy Commissioners, and it may be added, the feelings of a great part of the public. It must be admitted that the proceedings in the whole case, especially coupled with the execution of a poor wretched man named Wright, for an offence of a very similar character, have been exceedingly unsatisfactory, and although it cannot be denied that the law has been strictly observed in both instances, yet the result has strengthened the general opinion, especially likely to be caught up by the common people, that there is one law for the rich and another for the poor.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. GEORGE JOHNSON contributes a "Lecture on Dropsy, its General Pathology, Prognosis, and Treatment." The lecturer reviews the principal causes of dropsy, whether existing in the heart, the kidneys, or the blood itself, or being caused by some local impediment to the free passage of the blood. He also briefly describes the general treatment of dropsy, according to the nature of the disease which has produced it. Mr. HOLMES COOTE offers some observations on the "Causes of Death after the Operation of Lithotomy," and after confirming generally the statements made by other writers as to the average mortality after the operation, he proceeds to narrate some cases in which features of special interest were presented. Hæmorrhage is not a common cause of death, notwithstanding the number of vessels involved, but Mr. Coote relates two instances in which death resulted from this accident. Mr. GEORGE NAYLER contributes "Some Clinical Reports on Squamous Diseases of the Skin," his present subject being Pityriasis. This affection is usually classed among the scaly diseases, but one variety of it, the *P. versicolor*, owes its existence to the presence of a parasitic fungus, the *microsporon furfurans*. Ordinary pityriasis is best treated by ointments consisting of mercurial preparations with glycerine and cerate; and the parasite of *P. versicolor* may be destroyed by the use of sulphur vapour baths, and the local application of some mercurial ointment. Mr. RICHARD HOLT describes a "Case Presenting Anomalous Symptoms of Apparently Hysterical Character." The patient was a girl aged fourteen, a patient in an hospital at Milan, who had regular paroxysms of a condition somewhat resembling catalepsy from one o'clock p.m. until three, and from five p.m. until five a.m. being conscious and comparatively well in the intervals. All kinds of treatment were inefficacious.

THE 'MEDICAL TIMES AND GAZETTE.'

PROFESSOR SIMPSON continues his "Clinical Lectures on the Diseases of Women," his subject being still Acupressure which he strongly recommends for the suppression of hæmorrhage, in preference to the deligation of arteries. He now argues the question whether secondary hæmorrhage is more likely to occur with acupressure or with deligation and he comes to the conclusion that it is more likely to occur with the latter, because the common local causes of secondary hæmorrhage in deligation consist of ulceration or sloughing of the arterial walls, resulting from the ligature itself, while in acupressure there is no necessary ulceration at all of the arterial tube, its cavity being obliterated merely by laying its internal surfaces in contact by the pressure of the needle. Dr. Simpson, after giving some cases in illustration, goes on to consider the general and special objections against acupressure, the general being those which are usually brought against all new proceedings in surgery, and the special being chiefly the supposed injuries inflicted upon the veins and nerves. The former objections are classed by Dr. Simpson among those once urged by the French surgeons who opposed Ambrose Paré's proposal to tie arteries instead of closing them by the actual cautery and as for the supposed injury to veins and nerves, it is not proved that any such injury ensues; on the contrary, it is shown that in one case acupressure was applied to the sciatic nerve itself to restrain hæmorrhage from its central artery, and no inconvenience resulted. Dr. PEACOCK continues his "Cases of Unusual Slowness of Pulse," and relates an instance of remarkable slowness of pulse coming on during convalescence from rheumatic fever. In summing up the causes of this peculiarity, Dr. Peacock remarks that the undue slowness of pulse may result either from a want of proper muscular irritability, or from a defect in the special nervous endowment of the heart; it may exist where this organ is extensively diseased, and in other ca

it may occur where there is no reason to suspect any defect in its structure. The intermittent pulse bears a very close analogy to the slow pulse, and occurs under very similar circumstances; it may accompany different valvular and other diseases of the heart, but it may be present when there is no disease at all. Mr. JOHN CLAY, of Birmingham, relates a "Case of Multilocular Ovarian Tumour, in which Ovariotomy was Performed." The case was complicated by the existence of omental and uterine adhesions, for which the *adhesion clamp*, formerly described by the operator, was employed. A large portion of omentum was removed, measuring two and a half inches by five, by means of this instrument. The stump of the pedicle was left in the cavity of the abdomen, a procedure which is considered by Mr. Clay as preferable to the plan of fixing the pedicle between the lips of the wound, which may involve the dragging of the pelvic viscera and the risk of peritonitis. The case was quite successful, and the patient was better and stouter after the operation than she had been for many years.

THE 'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

Physiological Characters of Menstruation in Disease.

Dr. Gubler, of Beaujon Hospital, demonstrates in a recent publication, that the oozing of blood, which, in many women, occurs shortly after menstruation in the incipient stage of acute febrile or inflammatory disease, is entirely unconnected with the true catamenial function, and the periodic escape of an ovule.

The discharge is constituted by simple sanguineous exudation, as the extremely short interval which has elapsed since the last catamenial period would tend to show. In one case, for instance, Mr. Gubler observed, one week after the occurrence of the menses in a young woman, aged twenty-three years, simultaneous nasal and uterine hæmorrhage, both extremely slight, and coinciding with the first symptoms of typhoid. Now, it is scarcely presumable that in so short a period an ovule could possibly have reached maturity, and indeed congestion and a sanguineous discharge from the womb, when we recollect that the ovulum and the enveloping Graafian vesicle require no less than a period of twenty-eight or thirty days to attain their full development.

It is, moreover, an acknowledged fact that these discharges assumed to be menstrual, occur under circumstances entirely incompatible with ovulation. Mr. Gendrin, in his *Médicine Pratique*, mentions a family in which three successive generations of girls were affected with irregular uterine hæmorrhage between the ages of six and eight; one of the children, who did not present this symptom, was liable to frequent bleeding at the nose, which persistently occurred up to the age of sixteen, when the catamenial function became established.

The same peculiarity is observed in women who have reached the age at which menstruation ceases. Mr. Gubler has noted sanguineous exudations of this description in women of seventy and eighty.

Another circumstance may be adduced in proof that the discharge of blood from the womb is not necessarily connected with ovulation: some women who have never menstruated, in the usual sense of the term, have nevertheless borne children, and present on the surface of the ovaria distinct indications of ovulation. Last year, a girl, aged twenty-three, who had never menstruated, died at hospital Beaujon; Mr. Gubler performed the autopsy, and found eleven cicatrices on the left, and six on the right ovary, in every respect similar to those observed in women whose catamenial functions are perfectly regular.

Mr. Gubler also relates the case of a woman, aged twenty-six, who was admitted into hospital Beaujon for typhoid fever; sanguineous exudation from the womb took place in the early stage of the disease, and after her death, which occurred on the eighth day, the ovaries were carefully inspected, and no signs whatever of recent ovulation were detected on the surface of these organs. This was, therefore, an instance of what the author denominates uterine epistaxis.

The knowledge of this form of epistaxis rectifies the views hitherto entertained as to the reciprocal influence of the menses on the progress of the acute disease. Our predecessors doubtless exaggerated the unfavourable action of fevers and inflammatory affections on the catamenial functions, but we would fall into an equally obvious error, were we to consider these morbid conditions as an invariable cause of the premature return of the menses. The error originates in a confusion between mere uterine exudation and genuine menstruation.

"Acute disease," says Mr. Gubler, "may either suppress or accelerate the menses, or exercise no influence whatever on the performance of the function. According to all appearance, the period is seldom hastened by more than one week. Acute affections may, on the contrary, induce uterine epistaxis as soon as eight days after the last menstruation, and at any time before the recurrence of the next period. It is chiefly in the premonitory stage of fevers that the circumstance alluded to arises, but it may coincide with other dates of the evolution of pyrexiæ. The amount of the exudation, and its frequency are dependent on the gravity of the case, the tendency of congestion of the hypogastric viscera, the softening of the tissues, and the presence of the hæmorrhagic diathesis, consequent on a morbid condition of the blood. Uterine epistaxis is, for these reasons, more commonly met with in the incipient stage of thoracic and abdominal inflammation, of typhoid, erysipelas, or febrile eruptions, and especially in the prototypes of the class measles, scarlatina, and small-pox.

On the treatment it is unnecessary to dwell; medical interference being required in cases of copious hæmorrhage only. But the practitioner must in future be aware that he is not bound to remain inactive, as in the case of genuine menstruation.

Wound of the Penis.

Dr. Veilliard, of Yerres, recently communicated to the 'Société Medicale d'Emulation,' the case of a young farmer, who was severely bitten by a restive horse. The animal grasped with his teeth the man's trousers, and tore off the integuments of the penis, together with the glans. The stump left after this fearful mutilation was about one inch in length, but the tissues were so lacerated that the surgeon was unable to discover the meatus of the urethra.

Trifling hæmorrhage, supplied by one of the dorsal arteries, was checked by cold lotions. The use of refrigerants was persevered in, and after several hours of severe pain, the patient was at last enabled to evacuate the contents of the bladder. The accident occurred on the 3rd of March, 1861. On the following day the wound was dressed with cool anodyne poultices. On the 5th, a slight amount of fever supervened; retention of urine lasted twenty-four hours, and relief was obtained only after a bath; compresses impregnated with tepid water were applied to the injured parts and covered with oil silk. On the 6th, healthy suppuration was fully established, but the denuded penis was found covered with a dark-coloured substance of gangrenous aspect, which was detached by repeated lotions, and consisted of coagulated blood. The wound soon granulated, and six weeks after the accident a complete cure was effected.

Mr. Veilliard describes as a peculiarly painful symptom the convulsive retraction of both testicles, due to spasmodic action of the cremaster muscles, which, in young subjects, are powerful.

The case presented, in addition, several interesting particulars with regard to the genital and urinary functions. After cicatrisation, the new meatus presented the aspect of a funnel-shaped aperture, which readily admitted a catheter, a line and a half in diameter. After an interval of

eleven months the mutilated organ had considerably increased in size, and the singular facility with which the easily displaced skin of the scrotum and abdomen lend themselves to the repair of adjacent tissues accidentally destroyed, was here displayed in the most remarkable manner. The penis had then acquired a total length of eighteen lines, the scar was perfectly solid, and the funnel-shaped orifice was replaced by a circular ring into which converged a number of radiated folds. The stream of urine was small but sufficient, and erection was effected without pain. The young man's disposition had undergone the changes usually coincident with severe injuries of the external organs of generation.

In the debate which followed the communication of this interesting case, Messrs. Depaul and Larrey agreed with the reporter, M. O. Lecomte, that Mr. Veilliard had been entirely justified in not placing a catheter permanently in the bladder during the process of cicatrisation, a practice which amputations of the penis have shown to be unnecessary. This precaution is required only when phlegmonous inflammation determines retraction of the meatus. Under different circumstances, the catheter does not prevent the formation of traumatic stricture, and increases the tendency to feverishness, and to the nervous complications which frequently occur in wounds of this description.

THE NEW PHARMACOPŒIA.

This long expected volume has at last been completed, and it will soon be in the hands of the Profession. At the last meeting of the Medical Council, which was assembled for the purpose of electing a President in the place of the late Mr. Green, a copy of the new Pharmacopœia was presented to each member before the termination of the proceedings. We have been favoured with a view of the work, and we hasten to lay before our readers a brief account of the nature of the book itself, and of the novel features which it presents.

It is an octavo volume, consisting of four hundred and forty-four pages, and is divided into several parts, arranged under distinct heads. It is written in English, but the names of the substances used in the practice of medicine, are still presented in the Latin language, with the English equivalent name placed immediately underneath. The price is 10s. 6d., and as it will be almost absolutely essential for every Medical practitioner, as well as for all pharmaceutists in Great Britain or the colonies, to possess a copy, the sale is likely to realise a very considerable sum. The Preface, in fact, cautions all the members of the Medical Profession that in order to exercise their calling with safety, "it is incumbent on them to make themselves familiar with the changes effected in the present work." The Preface explains at some length the difficulties which have occurred in harmonising the conflicting views entertained in the different divisions of the United Kingdom, as to the consolidation of the several formulæ, and in presenting a uniform Pharmacopœia, instead of the three formerly existing, and it goes on to explain the general plan on which the contents have been arranged. We shall presently glance at this arrangement, but in the meantime, we may observe that, with regard to the essential point of the weights and measures, the latter remain the same as heretofore, but in the case of the weights, the grain is made the standard, 437·5 grains making an ounce, and 16 ounces making a pound. The use of the drachm and scruple weights is to be discontinued, as it would involve the use of fractions, and in prescribing, therefore, gr. xx., or gr. lx., or their multiplies, will be used, instead of the symbols ℈j. or ʒj.

The First Part of the new Pharmacopœia contains a list of the Materia Medica, or the substances used in medicine, arranged in alphabetical order, the Latin name being placed first, then the English name, then the chemical composition, and a general description of the substance mentioned, so as to distinguish it from all other bodies. This part is analogous in arrangement to the corresponding part of the old Pharmacopœia, making allowance for the numerous changes introduced.

The Second Part, also analogous to that in the old Pharmacopœia, contains the preparations and compounds, and describes the manner in which the different articles are obtained from the crude materials. This part appears to us to be a mistake, because a very large space is occupied by the description of formulæ, which are interesting enough in a pharmaceutical and chemical point of view, but which nobody needs to follow unless he chooses to do so. For instance, directions are given for the preparation of hydrochlorate of morphia, aconitia, and such like substances, but other and cheaper, or more expeditious methods may hereatter be devised than those here set forth, and, indeed, there are often already several equally efficient methods for obtaining the same substance, and the manufacturer will follow that which best suits his own convenience. Hence we think that the details given in this part merely swell the bulk of the book without really adding to its value.

The Third Part, unlike the corresponding part in the old Pharmacopœia, consists of a copious appendix, divided into several sections. Appendix A contains the articles employed in the preparation of medicines, although not medicines themselves, as for instance, ferrocyanide of potassium, which is used in the preparation of prussic acid together with a number of well-known substances, such as bread, white of eggs, &c. Appendix B is subdivided into sections,—1, comprising articles employed in chemical analysis, and with which chemists are well acquainted, the acids, alkalies, salts, &c., used as re-agents. 2. Test solutions for qualitative analysis, such as solutions of sulphate of copper, iodide of potassium, &c., all being of a certain and determinate strength. 3. Test solutions for volumetrical analysis, the object being to determine the quantity of a substance by the amount of its absorption by a given re-agent, as, for instance, nitrate of silver for determining the amount of chlorine, oxalic acid for alkalies, soda for acids, &c. Appendix C contains a table of symbols, and atomic weights; and this, with the index, completes the volume.

At present, we can only glance at some of the important changes made, many of which will, no doubt, be the subjects of active criticism, and, very probably, of disapprobation. Among the minor changes, we may observe that

Cerates are abolished, these substances being all merged in the Ointments; and Trochisci, or Lozenges, are, for the first time, introduced. Another change of a more important, but, as we think, of a very questionable character, is the insertion of the word opium in all the preparations which contain that drug. It is generally understood that it is sometimes undesirable for patients to know that they are taking opium, and, therefore, the word was excluded from the Pulvis Ipecacuanhæ Compositus, the Tinctura Camphoræ Composita, the Pilula Saponis Composita, &c., but now these compounds are written Pulvis Ipecacuanhæ cum Opio, Tinctura Camphoræ cum Opio, Pilula Opii Composita, &c.

Another change to which no objection can be made is the abandonment of the attempt to represent, in the name of each drug, the nature of its chemical constitution, and in every case, where it is possible, the common name is restored. Thus the chloride and the bichloride of mercury return to their old names of calomel and corrosive sublimate, the liquor potassæ arsenitis becomes the old liquor arsenicalis, the potassio-tartrate of antimony is the antimonium tartaratum, the nitrate of bismuth, bismuthum album, and so on. This change has been deemed necessary in consequence of the novelties continually springing up in chemical nomenclature, and the different views entertained by equally eminent authorities as to the constitution of bodies. The terminology of many names has been altered, and many of our old acquaintances appear in a novel garb; thus, for instance, Chlorine and Iodine are now Chlorum and Iodum, Calx Chlorinata is Calx Chlorata, Quina is Quinia, &c.

In concluding the present brief abstract, we proceed to notice the NEW MEDICINES introduced into the Pharmacopœia, and in a subsequent number we shall give a list of the old ones which have disappeared. We cannot, at present give more than the most important of the novelties, which, from the circumstance that they are now for the first time introduced into the National Pharmacopœia, we shall distinguish by capital characters. ACIDUM ACETICUM GLACIALE; ACIDUM SULPHUROSUM, which is a solution of sulphurous acid in water; AMMONIÆ BENZOAS; AMMONIÆ PHOSPHAS; ANTIMONII OXIDUM; ARGENTI OXIDUM; ARNICA; BEBERIÆ SULPHAS, Beberia being obtained from the *Nectandra Rodiœi*; BELA, Bael, obtained from the *Ægle marmelos*; CALCIS PHOSPHAS; CHIRATA, the chiretta; COCCULUS INDICUS; COLLODIUM; CUSSO, the kousso; DIGITALINE, the active principle of digitalis; FEL BOVINUM, or ox-gall; FERRI ARSENIAS; FERRI ET QUINÆ CITRAS, a very useful and well-known preparation; FERRI PHOSPHAS; FILIX, or Fern, of which the liquid extract is the officinal preparation; GLYCERINUM, Glycerine; HEMIDESMUS INDICUS, allied to Sarsaparilla, and of which a syrup is to be used; JALAPÆ EXTRACTUM; KAMELA, an anthelmintic obtained from the *Rottlera tinctoria*; LAURO-CERASUS, or cherry-laurel; LITHIÆ CARBONAS and L. CITRAS, lately introduced for the cure of gout; LUPULINA; PODOPHYLLI RESINA; POTASSÆ PERMANGANAS, and POTASSII BROMIDUM; SACCHARUM LACTIS, or Sugar of Milk, said to be useful in promoting the formation of lactic acid in the stomach; SANTONINUM, a vermifuge, obtained from the *Artemisia Santonica*; SCAMMONIÆ RESINA; SODÆ ARSENIAS; SPIRITUS PYROXYLICUS, or hydrated oxide of methyle, used in preparing the methylated spirits of wine; and ZINCI VALERIANAS, a very useful tonic and anti-spasmodic.

Many other drugs appear at first sight to be new, but they are really only old friends with new faces, and we have not included many substances which are merely varieties of other bodies already used and well known. The above, therefore, is by no means a perfect list of the novelties; but, as far as it goes, it may be relied upon with safety.

GENERAL CORRESPONDENCE.

THE CASE OF CANDLER *v.* PEAT.

"Audi alteram partem."

To the Editor of the Medical Circular.

SIR,—Had it not been for the interposition of numerous friends, I should not have condescended to notice the attempts made in your Journal, and various other newspapers, to lead the Profession and the public to believe that I was a party to the institution of this action, in which I have always studiously avoided interfering.

Having put myself in communication with Mr. Bennett, my former assistant, I received the accompanying letter, which fully explains the facts, and which I think should satisfy the Profession that I had no wish to appear in the case, but did everything in my power to keep out of the contention.

Regarding the letter I wrote to Mr. Bryant on the 27th of March, 1863, I have merely to state that, in doing this I was solely actuated by pure motives for the benefit of suffering humanity; that my only object was to ascertain if he could suggest any further mechanical contrivance for Candler's relief; and that the communication was a confidential one to Mr. Bryant as a consulting surgeon, which I understand was demanded from him previous to the trial, although not produced in court, and published, not only without Mr. Bryant's sanction, but after such had been asked and refused. This, the accompanying note from Mr. Bryant, will sufficiently prove.

Having said thus much, in order that I might free myself from the imputation attempted to be made on the minds of my Professional brethren and the public, I have merely to add that I shall not enter into any further correspondence on the subject, having now given, once and for all, an emphatic denial to the unwarrantable charge against me.

Trusting you will find a space for these communications in your Journal,

I am, yours sincerely,
JAMES HENRY SMITH, Surgeon.

Manningtree, Essex, Jan. 12, 1864.

(COPY OF MR. BENNETT'S LETTER.)

Chesham, Bucks, 11th January, 1864.

MY DEAR MR. SMITH,—I was very sorry to see by the MEDICAL CIRCULAR this morning, that it is attempted to impress on the minds of the Profession and the public, that you were the instigator of the trial, Candler *v.* Peat. Being your assistant at the time, and as I happened to be the person who answered Candler's summons to attend him, I must be allowed to have a knowledge of the facts of the case. I think it right that I should explain to the Profession that you always expressed your unwillingness to have anything whatever to do with Candler's case, and, when

you heard that an action was pending, you at once expressed your determination not to have any concern in the matter. More than this, you repeatedly sent me to tell Candler that you would neither appear in the case, nor have anything whatever to do with it.

On my first visit to Candler, he told me that he accidentally met a legal gentleman, who had occasion to come to Mistley, who asked him why he was lame, and on Candler telling him of his case, he (the lawyer) asked him why he did not make the surgeon pay for it, as he was sure he could recover damages: this, I believe, was the first instigation of the action. I am also aware that you did not fully examine Candler's foot, but referred him to several other surgeons.

The above ought, I think, to prove to the public that you endeavoured in every way to keep out of the matter, as I am confident you did.

Your frequent visits to Candler's house, in attendance on his son, might possibly leave the people in the neighbourhood to suspect that you were encouraging Candler to bring this action, of which I know you to be perfectly innocent.

I send you this letter, and you can use it if you think proper. With kind regards, I remain,

Yours faithfully,

HUGH BENNETT.

J. H. Smith, Esq., Manningtree.

(COPY OF MR. BRYANT'S LETTER.)

2 Finsbury square, January 11, 1864.

DEAR SIR,—Your partner, Dr. Cook, has just called on me respecting the publication in some papers of a private letter I received from you on March 27, 1863. I have no hesitation in stating that such a thing has been done without my sanction. Yours truly,

J. H. Smith, Esq. THOMAS BRYANT.

[This correspondence will be read with satisfaction by the Profession, and especially by the Medical practitioners of Colchester and its vicinity, who, we understand, are about to call a meeting upon the subject.—ED. MED. CIRCULAR.]

THE MEDICAL REGISTRATION ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—It is doubtless in the recollection of the majority of your readers that a society was established, a few years since, by a body of London Medical men, with a view of checking, by the aid of law, an amount of rampant quackery, that not only vitally injured the legitimate interests of the Medical Profession, but too often emptied the pockets and ruined the health of its unhappy dupes. The establishment of such a society was the more necessary, as the last "Medical Act" was *inoperative* for such a purpose, however good in theory; the highest Medical body, the Medical Council, declining to prosecute in any case, however flagrant, although armed with the prestige of government power.

The Society succeeded in putting down some of the more notorious quacks, and in checking the iniquities of others; and would, at this moment, have been in active operation, but for that miserable want of *esprit de corps* and short-sighted apathy to their *own interests* that more particularly characterise our profession above all other bodies of men.

In carrying out legal proceedings, in obtaining necessary evidence to convict, &c., &c., the committee, formed of well-known Medical men of standing, found their funds (never large) gradually exhausted, leaving them with a debt incurred solely *in the defence* of the professional interests of each one of us.

Now, I ask your readers, is it not degrading in the extreme, to us, as a Medical body, that our late respected President, Mr. Lavies, of Great George st., (Mr. Fergusson having preceded him in that honourable office), should be put to the annoyance of legal proceedings for debts, &c., incurred, which a few shillings from a fourth of the profession, even in town, would more than cover? Is it creditable that those members of the late committee, who, like Mr. Fergusson and Mr. Lavies, gave their time, trouble, and money to protect their brethren from the quacks, should be left to struggle, almost unaided, in assisting to remove an odium that falls upon each one of us?

As a subscriber to the fund for relieving Mr. Lavies from an unjust oppression, which we are bound to remove,

I remain, Sir, yours faithfully, M.D.

London, 13th Jan., 1864.

Subscriptions will be received and acknowledged by Dr. G. H. Wright, 23 Somerset street, Portman square.

IRIDECTOMY.

To the Editor of the Medical Circular.

SIR,—In your leading article, dated Jan. 13, you invite a discussion upon the subject of Iridectomy, intimating, at the same time, a bias in your own mind unfavourable to that operation, whilst you express your readiness to be convinced, if sufficient evidence of its value can be placed before you. With every respect for the opinions of yourself, and the many eminent surgeons who think with you, I beg leave to lay before you a few of the arguments in its favour. And first, with respect to glaucoma itself, although it must be confessed, the pathogenesis of this disease is somewhat obscure, yet there is abundant evidence to prove that one of its most characteristic features is tension of the eyeball, associated with choroidal congestion, leading to atrophy of the optic nerve, and destruction of the function of the retina, the latter effects, manifestly, the result of continuous tension; for a more detailed description of these changes, I must, however, refer the reader to Mr. Hulke's admirable paper in the 'British Medical Journal,' published in November last.

Tension of the eyeball, then, and consequent cupping of the optic disc being the earliest of that series of morbid actions which ultimately lead to glaucomatous degeneration various modes of treatment have been resorted to, in order to arrest the progress of the disease in this its earlier stage but all unhappily without success, until it occurred to Von Græfe that, as iridectomy gave relief in tension from closed pupil, it might also do so in glaucoma, and the result appears to have fully realised his anticipations. Such, then being the position of the question from the Iridectomist's point of view, it becomes our duty to consider what may be advanced on the other side of the question. The opponent of this operation urge, first, that it is unnecessary, inasmuch as all the good results obtained by it are as well, or better obtained by evacuation of the aqueous humour by tapping the cornea; and, secondly, that where the latter operation fails to do good, iridectomy will fail also. To this I can only answer, that I have myself seen the operation of tapping the cornea fail, though twice repeated, the disease meanwhile increasing, whilst the subsequent performance of iridectomy has been attended by the most satisfactory results, nor can I conscientiously say I have ever seen permanent benefit result from tapping in acute glaucoma. I hope to be able, in a future number, to give the particulars of a few cases bearing upon the point at issue.

I am, &c., CHIRURGICUS

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

MR. PRESCOTT G. HEWETT, PRESIDENT.

Some explanations were offered by Dr. Crisp on a case which he had shown at a preceding meeting of the Society.

EXFOLIATION OF THE MUCOUS LINING OF THE BLADDER.

A report by Dr. A. Clark, Dr. Murchison, and Mr. Henry Thompson was read on Mr. Henry Lee's case of Exfoliation of the Mucous Membrane of the Male Bladder. It affirmed the preparation to be a true exfoliation of a great portion of that membrane in an entire although partially disintegrated condition.

Dr. WILKS exhibited a similar specimen illustrating the condition.

Mr. MARTIN showed a large portion of membrane derived from the bladder of a woman who had long continued retention after labour. The urine, which was very offensive, had then to be drawn off twice daily. At about a month subsequently, retention recurred. Mr. Martin examined the parts, and discovered "a slough" presenting at the urethra, and he removed it. Next day there was again difficulty; and in the evening the patient herself withdrew a much larger portion exactly like the previous one. Relief followed immediately, and he had no doubt it was the mucous membrane of the bladder. She regained her health, but suffers still from irritability of the bladder.

[This preparation had been examined by the same gentlemen, and believed to be a genuine exfoliation also.]

Mr. S. WELLS showed two specimens in illustration of this condition. He thought the report on one specimen shown by Mr. Maunder the year before last was in error, and that it was not a portion of bladder from a lower animal as then suggested. He read an extract from the "Pathological Transactions" for the session 1861-62 describing the case. The two specimens he had to show to night, which had also been seen at the Obstetrical Society, were undoubtedly exfoliations from the bladder of the female. They were the results of long-continued retention. He referred also to a case of Mr. Liston's in a male subject.

Mr. H. THOMPSON would remark, in reference to the report which he and Dr. Murchison had made on the case Mr. Wells alluded to, that there was no kind of doubt that exfoliations *did* take place: the two specimens on which he *had just read* reports were examples, and at the *last meeting* he had described Mr. Liston's case as another example. But the question raised now by Mr. Wells was this: Was the case of Mr. Maunder, now two years old, a genuine example or not. He gave the reasons which induced him to believe that it was not, but that it was a bladder from one of the lower animals; stating that the late Dr. Knox and Dr. A. Clark, who examined it carefully, coincided in that opinion.

Mr. MAUNDER said he did not dissent from the conclusion respecting his case arrived at by Dr. Murchison and Mr. Thompson. He had not himself removed the membrane from the bladder; it was shown to him by the patient, who stated that she had done so.

Dr. HARLEY observed that there was an exceedingly strong resemblance between the genuine and the false material in these cases, and that the closest examination was necessary in order to distinguish between them; but this would not prove sufficient without a knowledge of the history and symptoms of the case.

Mr. CALLENDER referred to the necessity which existed for accompanying all specimens submitted to examination with a detailed written account of their history and symptoms, before sending them to a committee for report.

The PRESIDENT enforced this suggestion.

After a few more conversational remarks from Dr. Camps, Dr. Bristowe, and others on this subject, the next preparation was exhibited, namely,

CANCER OF TRANSVERSE COLON.

Mr. CALLENDER showed a specimen from a man who had suffered from abdominal tumour for two years. Of late it appeared to be pulsatile, and had diminished much in size suddenly. The post-mortem showed it to be medullary cancer of a very vascular kind. The coils of small intestine, glued together in front, made a kind of cavity, into which the transverse colon opened.

Mr. S. WELLS spoke of a case in which there had been some bronzing of the skin, which disappeared afterwards. It was a case of malignant disease in the abdomen.

The PRESIDENT referred to a large tumour in the abdomen of a gentlemen. In travelling home from abroad he was much shaken, a large evacuation took place, and the tumour became smaller. He died lately of phlebitis: there was a second evacuation of matter passed by stool shortly before death. The autopsy showed a mass of cancer opening into the transverse colon, which perhaps had shrunk down, and had to that extent been discharged by evacuation.

EXTERNAL CANCER.

Mr. ALLINGHAM showed a tumour of a cancerous character, which he had removed from the wall of the abdomen. It was enucleated with much bleeding. A fresh growth took place from the bottom of the wound, and this he had completely removed yesterday.

TINEA TONSURANS AND HERPES CIRCINATUS.

Dr. MURCHISON showed microscopic specimens of the fungus from these so-called distinct diseases, corroborating the growing belief that they were allied or identical. In two or more of each of these cases he had examined the fungus, and found it identical in each. In all, the disease got well during convalescence from an attack of scarlet fever, which appeared to have cured the skin affection.

Dr. HILLIER believed confusion to have arisen from two diseases being confounded under the name of herpes circinatus. One was a true vesicular disease without a parasite, a real herpes in a circular form; the other a furfuraceous disease with a parasite.

BONY GROWTH WITHIN THE EYEBALL.

Mr. COUPER showed this, removed by Mr. Critchett, relating the symptoms and conditions which led to the operation. The eyeball was nearly filled with the growth, which was undoubtedly bony.

Mr. MAUNDER showed

TWO CALCULI REMOVED BY MEDIAN OPERATION,

which he thought a favourable result from their size, and as showing that this operation was well adapted for such cases. He alluded to an eruption which followed immediately after the operation, and appeared to prove fatal. Eruptions occasionally did appear to follow operations. He would be glad to know the experience of surgeons on this point.

Dr. G. HEWITT illustrated the last-named fact from a case of his own after operation on the female urinary organs, and referred to Scanzoni, who described urticaria as succeeding to such procedures.

Dr. MURCHISON remarked on the likelihood of its being scarlet fever.

Dr. BROADBENT had seen three cases of scarlet rash following surgical operations, but not scarlet fever.

Dr. CRISP alluded to a case which was fatal after circumcision.

Mr. CALLENDER said that such eruptions were not uncommon after surgical operations. In a case of stone in a child a month ago, rash appeared twenty-four hours after the operation. The child was now suffering.

Mr. H. LEE stated his belief that such eruptions were not uncommon. He could instance three cases, one of death after circumcision on a child, after thirty-six hours; in the other there appeared to be secondary deposits in the system.

Mr. MARTIN alluded to a case.

Dr. HARLEY doubted whether these were all similar cases. A red eruption following a few hours after operation was not the eruption referred to by Scanzoni, which was urticaria, and which was not so uncommon.

Mr. WELLS thought these eruptions were common. Urticaria had followed ovariotomy, and petechial rash was a sign of blood-poisoning. He knew a patient who never had a speculum passed without a red rash following.

Dr. CAMPS differed with relation to blood-poisoning. In a case of hysteria in the male he had seen a fit followed by urticaria, and thought these rashes were nervous, and not blood-poisoning.

Dr. HILLIER said that this distinction must be drawn. Urticaria might be, and undoubtedly was, often nervous, and not the result of blood-poisoning.

COLLOID GROWTH.

Mr. CANTON removed this from the leg. It had been of little inconvenience during life, although large. It lay close to the sciatic nerve. The specimen was removed ten days previous to the meeting, and was preserved perfectly fresh in appearance by keeping it in a vessel with the vapour of chloroform.

ANEURISM OF THE AORTA.

Mr. C. CAY showed for Mr. Trotter a preparation of this affection from a sergeant in the Coldstream Guards. Very

few symptoms indeed had been observed, and sudden death occurred from bursting into the œsophagus.

MALFORMED AND HYDROCEPHALIC CHILD.

Mr. CALLENDER showed the body of a young child. He would call attention to certain derangements of the cephalic nerves resulting from hydrocephalus. The child became the subject after birth of double talipes (calcaneus).

JANUARY 5TH, 1864.

REPORT OF THE COUNCIL.

In accordance with the established rule of the Pathological Society, its Council presents to the members an annual report, embodying a brief account of the progress which has been achieved during the past year, as well as of the position and prospects of the Society.

It is a noteworthy fact that throughout its whole career, a period of eighteen years, the Council has been enabled to furnish an annual record of progressive prosperity. No exception to this happy experience has yet been furnished; and it is with no small gratification that now, on the occasion of another anniversary, your Council is able to announce, not merely that the present report maintains the character of its predecessors, but that it records an amount of success beyond that of several preceding years. To commence with the subject of finance:—

The total receipts for the past year have amounted to 353*l.* 1s. 4d.; of which 12*l.* 8s. 1d. has been realized by the sale of the "Transactions," and 5*l.* 14s. 3d. as dividend from stock, leaving as the amount of subscriptions the sum of 334*l.* 19s. Of this, 45*l.* 3s. has been received as life fees, and as composition fees from non-resident members; and will, in accordance with previous practice, be invested in Three per Cent. Consols. Besides this, there is a balance of 190*l.* 18s. 5½d. from the preceding year, making a total of 543*l.* 19s. 9½d.

Of this, 119*l.* 19s. has been added, by order of the Council, to the Society's funded property. The total expenditure amounts to 329*l.* 3s. 3d.; leaving in the treasurer's hands a balance of 78*l.* 2s. 6½d., to be carried forward to the account of the current year.

The amount of stock in Consols held by the trustees for the Pathological Society is now 259*l.* 13s. 5d.

Next, in relation to numerical strength, it should be stated that the Society is at this moment constituted by a larger number of members than at any previous period of its existence. The average attendance at its meetings is also higher—a fact which demonstrates the increasing interest which attaches to the operations of the Society.

The supply of pathological specimens has been more than ample, and, on most evenings, more than sufficient for examination, to say nothing of discussion. If any ground of complaint could possibly be alleged, it arises from an absolute superabundance of valuable examples of morbid product. The often imposing list, the reading of which commences the proceedings of each meeting, sometimes suggests such a reflection as the following:—"It is true that each of these preparations is intrinsically valuable and interesting—that it is necessarily so to the exhibitor, who has watched narrowly the phenomena which have marked its development; but has it been considered whether the specimen subserves also that purpose which is, after all, the higher one—namely, to afford interest and perhaps instruction to many of the hundred members whose time will be occupied by its examination, or of the four hundred who pay for its record in their annual volume?"

In conclusion, it remains only for the Council to state that the energy and activity which have already signalised the career of the present session, offer the prospect of a valuable forthcoming volume as the result of those useful labours which so many of the members have prosecuted on behalf of the Society.

The adoption of the report was moved by Dr. Johnson, seconded by Dr. Murchison, and unanimously carried.

Mr. CURLING next, in appropriate terms, moved the thanks of the Society to the retiring officers.

Dr. WILKS seconded the motion, which was unanimously carried.

The PRESIDENT next adverted to the fact, that the Society would this year lose the services of one of its highly valued secretaries; and with a warm eulogium on his long-sustained efficiency in the post he was about to vacate proposed a special vote of thanks to Mr. Henry Thompson.

This vote having been carried by acclamation, Mr. Thompson replied.

OBSTETRICAL SOCIETY OF LONDON.

JAN. 6TH, 1864.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows:—Alfred G. Brown, Esq., Woolwich; Dr. Fleetwood Buckle, Royal Mint; William Gilbee, Esq., Melbourne, Australia; Edward Head, M.B., Harley street; L. J. Martin, M.D., Melbourne, Australia; Dr. Playfair, London; Dr. Pugh, Melbourne, Australia; Dr. Ritchie, London; B. M. Walton, Esq. Hurstpierpoint; Dr. W. M. Whitmarsh, Hounslow.

Dr. MADGE gave a short account of a case of

LESION (RUPTURE?) OF THE PLACENTA,

occurring in a patient who aborted two or three days after falling downstairs. She was four months and a half pregnant. She was carrying a pitcher of water upstairs, and fell forwards, the bone of her stays coming with great force against the lower part of the abdomen. The placenta contained a clot of blood, which Dr. Madge was inclined to believe was the result of rupture of the placenta at the time of the accident.

Dr. OLDHAM and Dr. DRUITT doubted the correctness of the view expressed by Dr. Madge.

Dr. E. DAY related a case of

EXTRA-UTERINE FŒTATION, AND INDUCTION OF PREMATURE LABOUR.

A specimen was exhibited consisting of the uterus of a woman in whom premature labour had been induced, together with an old extra-uterine fœtation. She was attended at King's College Hospital in her sixth labour in 1859, when a tumour was felt behind the uterus; this was pushed up and labour proceeded well. In January, 1861, Dr. A. Farre induced premature labour at the eighth month, the tumour still existing. In August, 1862, she was delivered of a seven months' child, the tumour being still present. She became pregnant in January following, and came again under notice in May. Labour was induced at seven months and a half by an air caoutchouc dilator. The membranes were subsequently ruptured, turning performed, and a dead child extracted. The woman died two days after from floodi The post-mortem examination showed that the tumour behind the uterus in the recto-vaginal pouch, and which during life the size of a goose-egg, consisted of a fœtus the size of one from three to four months old, enclosed in thin cyst, attached to the peritoneum on the right side of rectum. The right Fallopian tube contained a tumour apparently the remains of an organised clot, and remain decidual membrane.

Mr. S. NEWMAN, of Bury St. Edmunds, exhibited

THE GUIDE-HOOK: A NEW OBSTETRIC INSTRUMENT.

The instrument is simply a blunt hook, with the addition of a prow or guide on the convex side. The addition of guide is to favour the adjustment of the hook into many positions in which a hook is required, to assist in breaking up the base of the skull, and in sundry other manipulations.

Dr. DAY exhibited a specimen of Adhesions between Uterus and the Rectum, dragging down the fundus; and inquired of the Society as to the possibility of stretching such adhesions by treatment.

Dr. OLDHAM and Dr. GRAILY HEWITT made some remarks.

ANNUAL MEETING.

The Report of the Auditors of the Accounts of the Society was first read. The balance-sheet showed a balance in hands of the Treasurer of 225*l.* 12s. 3d.; while, in addition to this, there was invested in consols the sum of 55 which latter sum 150*l.* had been invested in the course of the last year. The amount of subscriptions received d

the year was 474*l.* 12s. The sale of the "Transactions" during the year had realised 55*l.* 17s. 1d.

It was moved by Dr. ROUTH, seconded by Dr. CLEVELAND, and carried,—That the Report of the Auditors be received and entered in the Minutes. Dr. Routh alluded in terms of very congratulatory character to the exceedingly satisfactory financial position of the Society, which he considered reflected the greatest credit on the management.

Mr. BRYANT and Dr. TILBURY FOX moved and seconded a vote of thanks to the President and Officers of the Society for their valuable services during the past year.

Dr. OLDHAM and Dr. GRAILY HEWITT returned thanks.

The list of "Donations" during the year having been read, the President announced the result of the ballot for Officers for 1864 to be as follows:—Hon President: Sir Charles Locock, Bart., M.D.—President: Dr. Oldham.—Vice-Presidents: Dr. Druitt, Dr. Gream, Dr. Greenhalgh, Mr. Hardey (Hull), Dr. Swayne (Bristol), Dr. Tanner.—Treasurer: Dr. Barnes.—Hon. Secretaries: Dr. Graily Hewitt and Dr. Hicks.—Other Members of Council: Dr. Clay (Manchester), Dr. Cleveland, Dr. Hall Davis, Dr. Drage (Hatfield), Dr. Gervis, Dr. Hall (Brighton), Mr. Harrison (Reading), Dr. Langmore, Dr. Meadows, Dr. Madge Mr. Mitchell, Dr. Murray, Mr. Ray, Dr. Richards, Dr. Tyler Smith, Mr. Symonds (Oxford), Dr. Tapson, Dr. Wilson (Glasgow).

The PRESIDENT then delivered the

ANNUAL ADDRESS.

He remarked that the task before him was of a pleasing character. He had nothing to recount but progressing prosperity on the part of the Society. During the past year not a jar or discord had occurred. Forty-one new Fellows had joined the Society, making the present number of Fellows 535. Amongst these were gentlemen from our most distant colonies, as proof of which he might mention that this very evening three members of the profession residing at Melbourne had been elected Fellows. In Constantinople, in India, in New Zealand, Jamaica, New South Wales; the Society had extended its ramifications. The character of the debates, the authority of its judgement on disputed points, the large sale of the Society's "Transactions,"—all these facts showed its popularity, and the estimation in which it was held by the Profession. He doubted whether those who still withheld their presence from the Society rightly measured the great interest felt by practitioners in all relating to obstetric practice. That interest he believed to be even stronger than that felt in the other great divisions of our profession. The independent and efficient organization of this Society was required to do for obstetrics what the previously existing Societies had failed to effect.

The financial state of the Society was highly satisfactory. 550*l.* invested in the funds, and a balance of 225*l.* at the bankers, also ready to be invested, was the financial expression of the condition of the Society at the end of the fifth year of its existence. The Society possessed nearly nine hundred volumes of works relating to obstetrics. During the past year the Council had considered the possibility of making this library available for use by the Fellows. On the whole, it was considered advisable to wait, more especially as there had been reason to think that accommodation might be had in the present location of the Society. The matter was still *sub judice*, and the Council would carry out the idea at the earliest possible moment.

Six additional Honorary Fellows had been elected during the year—Professors Faye (Christiana), Braun (Vienna), Depaul (Paris), Martin (Berlin), Dr. Beatty (Dublin), and Dr. Pagan (Glasgow). From Prof. Scanzoni, one of the first Honorary Fellows, the Society had received the gratifying compliment of the dedication of his work "On Chronic Metritis," in recognition of the manner in which he had advanced gynæcology.

Four volumes of "Transactions" had been published, and a fifth would appear in the course of a few weeks. It was quite unnecessary for him (the President) to remark on the value of the contents of these volumes. They formed an important part of existing obstetric literature. To certain of the papers therein contained the profession was indebted, amongst other things, for the establishment of the operation of ovariotomy as rational and legitimate. He had often wished that the discussions before the Society had embraced a revision of the precepts for the management of the puerperal state. No subject was more important, involving as it did the comfort and health of thousands. It involved another point of interest: What was the length of attendance included in the midwifery fee? In a court of justice he had recently been asked this question, and his reply was that a week was enough for ordinary convalescence. He had found that many still acquiesced in the old notion of a puerperal "month," during which attendance was, they considered, obligatory. There should be some uniformity on this point. He contended that the limit should be, not a puerperal month, but a puerperal week. He could only understand the need of medical care for a month on the supposition that the precepts which are laid down in some of our midwifery books steadily induce a debility in the first fortnight, which requires a drawling convalescence in the next two weeks to overcome. Parturition and its immediate effects should be divorced from disease, and not made to wear its likeness. A puerperal month, under the guidance of a monthly nurse, was easily drawn out. He knew no reason why, if a woman was confined early in the morning, she should not have her breakfast of tea and toast at nine, luncheon of some digestible meat at one, her cup of tea at five, her dinner with chicken at seven, and her tea at nine; or the equivalent according to her habits of living. Common sense must guide in the selection of articles of food. Excess and stimulants must be avoided; so also gruel and slops. Such had been his practice for the last twenty years, and by it he could affirm that the process of involution was greatly assisted, and various disorders prevented. The patient should be removed to her sofa in two or three days. He would not now pursue the subject further.

In conclusion, the President stated that during the year three Fellows had been lost to the Society by death. He begged to congratulate the Society on its present prosperity, and trusted it would increase.

A vote of thanks to the President for his interesting address, proposed by Dr. Druitt and seconded by Dr. Greenhalgh, was carried by acclamation. The Society then adjourned.

Births, Marriages, and Deaths.

BIRTHS.

CAPPER.—On the 8th instant., at Mentone, Alpes Maritimes, France, the wife of Jasper Capper, M.D., of a daughter.

DEMPSTER.—On the 17th of Nov., at Beechworth, Victoria, the wife of J. C. Dempster, M.D., of a daughter.

DUNCAN.—On the 9th inst., at Great Marlborough street, the wife of P. C. Duncan, M.D., of a son.

HAMMOND.—On the 11th inst., at Ipswich, the wife of C. W. Hammond, M.D., of a son.

SHORTT.—On the 8th inst., at Waterloo-terrace, Dublin, the wife of Dr. Shortt, of a son.

WIMBERLEY.—On the 11th inst., at Bedworth, Warwickshire, the wife of C. C. Wimberley, M.D., of a daughter.

MARRIAGES.

KING—BIGG.—On the 9th inst., at St. Marylebone Church, E. Holborow King, M.R.C.S., of Welbeck street, Cavendish square, and Landsdowne road, Kensington Park, to Sophia, daughter of W. Minshull Bigg, Esq., of Stratford place.—No Cards.

DEATHS.

BAYNE.—On the 10th inst., J. Bayne, L.F.P. & S. Glas., of Dumbarton.

HANNAH.—On the 10th inst., J. L. Hannah, M.D., of Brighton.

JAMES.—On the 9th inst., at Nelson terrace, Stoke Newington-road, J. W. Wilmot James, L.R.C.P.Ed,, aged 37.

NEWBIGGING.—On the 10th inst., at Heriot-row, Edinburgh, P. S. K. Newbigging, M.D.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 7th January, 1864: — Joseph Morris, Birmingham; Joseph Smith, Lozells, Birmingham; Henry Mackenzie Parkes, Guy's Hospital; George Elkington, junr., Birmingham.

The following gentleman also, on the 31st December, 1863, passed his first examination:—Richard Rothwell Daglish, Guy's Hospital.

GUY'S HOSPITAL.—At the annual conversazione, held at Guy's Hospital on the 22nd December last, Mr. Ernest Edwards showed a very interesting series of photographic dissolving views relating to Shakspeare, being from negatives taken by himself as illustrations for a book about to be published; as well as some life-size portraits, one of them being a striking likeness of the late W. M. Thackeray. Mr. Edwards concluded by showing and explaining the well-known "ghost effect," which drew crowded audiences the whole evening.

HOW TO PREVENT CHLOROFORM ACCIDENTS.—There are few subjects of a more practical nature in general surgery and medicine than to ascertain the best mode of administration of chloroform, so as to avoid these melancholy and disastrous deaths that so often follow its use. As in the later treatment of pneumonia or hip-joint disease we have simplified our practice by removing certain coincidences and recognising them as coincidences, so in chloroform administration a new key has been furnished to the physiology of anæsthesia under that agent by recognising that the "cardiac syncope" of former years is a coincidence or *post mortem* change: and that the condition of the respiration under chloroform is far more important than the condition of the heart. It is of little advantage, or useless indeed, to strive to rouse up a flagging pulse but through the lungs and diaphragm: and we have lately found, in practice in hospitals, that this is satisfactorily effected, not by galvanism or such like to the cardiac nerves, as formerly recommended, but by alternating ether with chloroform, which acts as a new stimulus of some kind to the air-cells of the lungs, and to the curiously complex nerves of the larynx, which are associated with the phrenic and with the diaphragm. There is much confusion existing in our standard books as to the nature of accidents from chloroform; more particularly the contraindications to chloroform. This has been a work of time to correct, as they were at first imperfectly guessed at as belonging to disease of heart. Most unnecessary and damaging coroner's inquests have been held on bodies, on the assumption that a mere *post mortem* result in the heart should have been during life anticipated by the surgeon, when probably a simple emotion of the mind (fright or nervousness), causing simple syncope, led to the accident, without a trace of cardiac disease. Foremost of the real contraindications, I think, is the nervous exhaustion which attends loss of food or delirium tremens. Here the patient, as in puerperal mania, should at least not have chloroform, except he shall have first obtained some natural sleep, with renewal of nervous energy in those parts of the nervous system connected with reflex and respiratory action. Thus on a field of battle, as in America lately, one sees accidents from neglect of this. Hysteric patients, or those subject to fainting fits, require great attention; and for opposite reasons. In hysteric patients, there is excess of irregular morbid nervous action, which requires a large quantity of chloroform, sometimes many ounces, to overcome it; but in patients subject to fainting fits, a few drops of chloroform may produce similar results. This form of exhaustion is not easy to describe, as it cannot be traced to the usual shock of enormous operations like ovariotomy, amputation of the thigh, etc.; for in these the law of tolerance is very marked.—'Dr. Kidd on Chloroform.'

BRITISH SURGERY IN PARIS.—At a late meeting of the Surgical Society of Paris, three well-known surgeons belonging to this country were unanimously elected foreign associates, viz., Mr. Robert Adams, of Dublin, Mr. Joseph Hodgson and Mr. James Paget, both of London.

ST. BARTHOLOMEW'S HOSPITAL.—The Governors of Bartholomew's Hospital have, at their last Court, ele Dr. Burrows Honorary Consulting Physician, in recogni of his services of thirty years' duration as physician assistant-physician to the Hospital. This act is the n complimentary as no previous physician upon his re ment has had a similar honour conferred upon him.

THE CINCHONA PLANT IN JAMAICA.—In the autum 1860 a quantity of the seeds of several species of the chona were received at Jamaica. By the month of Oct following, about 400 healthy plants were raised, but o to the low level at which they were planted, more than perished. They were then removed to an elevatio about 4,000 feet above sea level, with the best results. twelve months, a plant of the red bark (Cinchona s rubra) had attained the height of 44 inches, with le measuring 13½ inches in length, by 8¾ inches in brea The culture of the Cinchona micrantha (grey bark) has been so successful; the leaves are, however, much la As there is abundance of land in the island possessin the conditions requisite for the growth of the plant, anticipated that a large supply may shortly be produce

THE HEREFORD COUNTY LUNATIC ASYLUM is a to be enlarged to accommodate an increase of 100 and 120 female patients. The plans of Mr. Fuljames adopted.

HÆMORRHAGE FROM THE GUMS.—It is often extren difficult to restrain the hæmorrhage consequent on the traction of a tooth. I was recently consulted by a yo woman suffering from an accident of this description: was deadly pale, faint, and threw up, without cessati mouthfuls of blood, which issued from the alveolar of t second large molar, which had been extracted with difficulty. Sesquichloride of iron and sulphuric acid h in vain been resorted to. I applied over the alveola small pyramid of discs of agaric, piled up sufficiently h to rise above the the level of the adjacent teeth, so that mere act of closing the jaws caused powerful pressure the seat of the hæmorrhage. The escape of blood was mediately checked, and did not return in the morning w the dressing was removed. I may also be permitte allude to an equally simple and efficacious metho arresting the flow of blood from leech-bites. This always be effected by slight pressure with the tip of finger. This procedure is invariably successful, and be safely entrusted to the watchful care of a mothe 'Journal of Practical Medicine and Surgery.'

SEAMEN'S HOSPITAL SOCIETY.—The quarterly cour the governors of this charity was held on Friday; Cap Maude, R.N., in the chair. The receipts amounte 1,816*l.* 10s. 1d., and the expenditure to 1,883*l.* 14s. showing an excess of expenditure over receipts of 67 5d., which, added to the previous deficiency, amounte 881*l.* 1s. The patients admitted from the 1st October t 31st December, 1863, numbered 632, of whom 4 were f British ships, 497 from merchant ships, and on board the 30th of December, 131.

CITY OF LONDON HOSPITAL FOR DISEASES OF CHEST.—The sixteenth annual general court of the go nors of this institution was held on Friday at the Lo Tavern; the Lord Mayor in the chair. The report, w was adopted, stated that the number of in-patients t treatment during the year had been 447, being seven than the previous year; 409 had been relieved, 38 died. The out-patients during the year amounted to 1(being an increase of 1,439 over the preceding year. average weekly attendance had been 1,136, or 95 than the previous year. The total number since the tution was established (1848) was 90,716. The fin statement showed that there had been received durin year:—Donations, 5,438*l.* 12s. 8d.; annual subscrip 2,016*l.* 10s.; bequests, 205*l.*; collections after sermons, 0s. 5d.; interest, 73*l.* 18s. 4d.; incidental sources, 2 3d.; making, with balance of 1,330*l.* 4s. 11d., at the ning of the year, a total sum of 9,207*l.* 12s. 7d. Ther been expended for the maintenance of the charity a su 5,158*l.* 10s., and on account of new wing, 3,614*l.* 19s., a total expenditure of 8,773*l.* 9s., leaving a balance a

banker's of 434*l.* 3s. 7d. The legacies comprised 200*l.* from the late Mrs. Mary Duncan, and 5*l.* from the late Mrs. Hadden. The cost of the new wing would amount to about 7,000*l.*, the claim yet unsatisfied of architect and contractors being about 4,000*l.*

PERSEVERANCE.—The chair of Surgery of the Faculty of Turin was lately competed for by Messrs. Pacchiotti and Bottini. The former beat his adversary and obtained the professorship, for which he had competed *five times* previously.

THE DEAN OF THE PARIS FACULTY.—M. Rayer, whose deanship had some time ago been the occasion of unruly and noisy expressions of discontent on the part of the students, has just resigned.

SANITARY MEASURE AT BOMBAY.—Important sanitary measures are being taken at Bombay. The unhealthy condition of the town, which has caused the deaths of so many Europeans as well as of the native population, will now be materially changed. The report of Mr. Rawlinson, C.E., has been adopted, and the Government have voted thirty-three lacs of rupees, or 332,000*l.* towards carrying the work into effect.

FEVER IN SWANSEA.—At the last meeting of the Swansea Board of Guardians it was announced by the chairman that measures were immediately to be adopted to purify that part of the town in which fever has lately been so prevalent.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JAN. '20. — *Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.

THURSDAY, JAN. 21.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Tyndall, "On Experimental Optics," 3 p.m.; Chemical Society, Mr. W. M. Watts, "Absorption of Mixed Gases in Water."—Dr. Thudichum, "On Urochrome, the Colouring Matters of Urine, 8 p.m.

FRIDAY, JAN. 22. — *Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, Mr. W. R. Grove, Q.C., "On Boiling Water," 8 p.m.

SATURDAY, JAN. 23.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, Mr. John Lubbock, "On the Antiquity of Man," 3 p.m.

MONDAY, JAN. 25. — *Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JAN. 26.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Diet of Infancy and Childhood. By S. Barker, M.D. London: R. Hardwicke, 192 Piccadilly.

Quarterly Abstract of the Medical Sciences, July to December, 1863. London: John Churchill and Sons, New Burlington street.

The Teeth in Health and Disease. By R. T. Hulme, F.L.S., &c. London: H. Baillière, 219 Regent street.

The Church of England Temperance Magazine.

The Medical Mirror for January, 1864. London: H. K. Lewis, 15 Gower street, North.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

M.D.—We shall be happy to insert every case which may be interesting and instructive; the object of our Journal being to give the widest circulation to the experience of Medical men, that others may have an opportunity of studying and profiting by it.

DR. DRYSDALE'S letter arrived too late for insertion this week.

THE abstract of Mr. Nunn's Clinical Lecture on Necrosis of Cancer is unavoidably postponed until next week.

V.R.—We are sorry to have heard of the fatal termination of Dr. Maurice Collis's case, upon which he very recently operated for ovarian disease. We believe the cause of death to have been obstinate vomiting, which exhausted the sufferer. There was another complication—typhoid peritonitis.

A SURGEON.—There was an epidemic of tetanus some time since in our London hospitals, and some cases were fatal; the most probable cause was the excessive coldness of the season.

DR. A—e.—There are two most extraordinary cases of impalement per vaginam on record: one by Dr. Bryan, of Aberdeen, Mississippi, and the other by Dr. Sargent, of Worcester (U.S.) The former was that of a negress, in whom the tobacco stick passed per vaginam up to the intercostal space between the eleventh and twelfth ribs of the right side; the latter, that of a lady who impaled herself on the handle of a pitchfork, which passed into the vagina, and ran up along the left side for a distance of twenty-two inches, till it reached the Scaleni muscles. Both cases recovered.

TRURO.—We have seen and examined the Mincers made by S. Nye and Co., of Wardour street, and they appear to be particularly suited for invalids, children, and those suffering from bad teeth. They are ingenious, well constructed, and cleanly.

THE ROYAL INSTITUTION.—The card has been received.

DR. M. M.'s wishes shall be attended to.

F.—Olonitis or Oulonitis means inflammation of the gums; being derived from *οὖλον*, the gums.

R.—Orthopædic; the derivation of this word is frequently mistaken, it is from *ὀρθός*, straight, and *παῖς*, a child. The very spelling of the word shows it not to be a derivation of *πούς*, the foot.

DR. JASPER CAPPER, MENTONE.—The letter and inclosure have been received, and the notice shall appear.

THE OBSTETRICAL SOCIETY.—The Report has been received.

DR. MCKECHNIE.—We beg to apologise to our esteemed subscriber and friend for the accidental substitution of an *r* for the second *c* in his name.

P.—Dr. G. de Gorrequer Griffith published an interesting case in one of our numbers of last year, in which a rubeoloid eruption followed the use of morphia. "There are two effects," says Dr. Neligan in his 'Medicines—their Uses and Mode of Administration,' "occasionally produced by morphia and its salts, when taken in medicinal doses, evidently dependent on idiosyncrasy, which are not caused by opium—namely, a peculiar sensation of itchiness over the whole surface of the body, in some cases attended even with a cutaneous eruption."

DR. M. is informed that it is necessary for the pupil to have served for five years "after the manner of an apprentice," but indentures are not absolutely necessary.

THE CASE OF SYMM V. FRASER AND ANDREWS.—We intended to insert Dr. Tunstall's reply to Dr. Fraser's letter this week, but, as the latter gentleman has written a rejoinder, we should be obliged in fairness to print that also, and thus too much of our space would be occupied. We are the less inclined to alter this resolution on our part as no new facts are elicited by the supplementary correspondence.

WE believe that the American Kitchener, supplied by Mr. Riddell, Cheapside, fully justifies all that is stated of it. We have had one in use for some time, and have found it cleanly, economical, and most convenient. It is suitable for the largest institutions or the smallest families.

MR. W. M. A. B. shall receive a private note.

MR. T. P. shall also receive a private note.

W.—The fact that Chabert was able frequently to enter an oven, the heat of which varied from 400 deg. to 600 deg., proves directly the non or feebly-conducting power of dry air.

To the Editor of the Medical Circular.

SIR,—Can you tell me where white round graduated phials 6 and 8 oz. can be obtained? I am, &c.,

Jan. 14, 1864. H. M. D.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT'S Analy gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxyge equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.

OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Op Race Glasses, and Telescopes, by the best London Makers.

Catalogue of Cameras and Lenses, also of Pocket and Dissecting Cases forwarded on receipt of Postage Stamps.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOU

DR. HASSAL'S REPORT:—

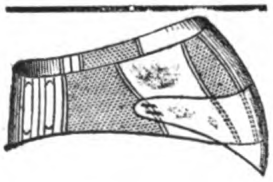
"I have carefully analyzed Blockley's we known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishi beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D Lond Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quar RAGGETT, late Blockey, 21 Duke st., St. James's Established 100 years.

MR. P. BOURJEAURD'S REGISTERED SPIRAL ELASTI

BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 11 RUE DES DEAUX-ARTS, PARIS.

Mr PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in cases indicating their necessity, and begs respectively to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating their necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatuses, Ankle, Knee and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 11 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies, who may insure her attendance in Davies street, or at their own establishments, by favouring Mr Bourjeaurd with instructions according to their own preference.—Poor Patients are supplied at a reduction of thirty per cent. lower than the imitations.



AT HOME FROM TEN TILL SIX.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34 JERMYN STREET,

Beg to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELT, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

*** Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle. Directions for Measurement sent by post.

N.B.—A Liberal Discount to the Profession.—A Female to attend on Ladies.

The Pneumoclime.—An Address to

the Profession, by Mr. JEFFREYS, on this his latest improvement the RESPIRATOR, and proposing another climate instrument, the PNEUMOTHALP.—Through a typographical omission, the above letter was printed without its Author's address—"Belvidere road, Upper Norwood, Surrey, S."

John W. Tweedie, Publisher, 337 Strand, is Chief Agent for the PNEUMOCLIME, in its several forms of Oral, Hand-Oral, Day and Night OrinaSals, and Nasal.

H. Silverlock's Medical Label Ware-

house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.

YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.

CONDENSED SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.

LABEL DRAWERS, for Dispensing Labels of various sizes.

Catalogues sent by post.

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 9s. 8d. Households (recommended for bread-making), 9s. 0d.; Seconds, 8s. 4d.; Wheat Meal for brown bread, 8s. 4d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms **Cash. A half sack delivered free to any railway station 200 miles. German yeast.**

Whicker and Blaise, late Savig

and Co., Wholesale and Retail Cutlers and Surgeons' Instru Makers, No. 67 St. James's street, from Pallmall and King street, Lo and at their Manufactory, Young's place, Wood street, Westminster.

Instruments made of the Lamina

DIGITATA, Uterine Tents, see 'Med. Times and Gazette,' 28th 1863, page 558, T. G. Wilson, on Uterine Tents. Couper's di Uretha Bougies and Styles for dilating the Lachrymal duct, as used Royal Ophthalmic Hospital, Moorfields, may be had of C. W. KRO 241 Whitechapel road, London.

Microscopic Glass.—Thin Glass

Mounting Objects, in squares or circles. Slides 3 in. by o and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON 89 High Holborn, London.

N.B.—Aquariums, Fern Cases, and Glass Shades.

Kamptulicon, Floor-cloth. — T

attention of the Medical Profession is requested to be given many advantages of this article as a floor covering, for the Wards o PITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet and w the tread, will not hold dust, is very easily and quickly cleaned, a stand any amount of hard wear. It has already been adopted in hospitals.

GOUGH and BOYCE, 12 Bush lane, Cannon street, London.

Original Patentees and Manufacturers.

Forwarded to all parts of the Country.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

BY ROBERT HUNTER SEMPLE, M.D.,
Senior Physician to the St. Pancras and Northern Dispensary.
Physician to the Standard Life Assurance Company.

(Continued from page 6.)

Before any person can be competent to pronounce an opinion as to the diseased condition of any organ, he ought to be fully acquainted with its healthy state, and with the varying phenomena which it may present consistently with the performance of its normal functions. Thus in the case of the heart, it is not only necessary to be fully acquainted with the natural impulse and the natural rhythm of the organ, but also to be aware that certain disturbances in these particulars are not inconsistent with healthy action. Thus the impulse of the heart and the rapidity of its movements will be increased by exercise, by eating, and by even the moderate use of stimulants, and its functions will also vary according to the recumbent or standing position of the patient. It is also necessary to bear in mind that mental impressions may act powerfully upon the rhythm of the heart, either increasing or diminishing its movements or its impulse, or disturbing the regularity of its action. These remarks, although they may appear of a commonplace nature, are of very great importance in practice, and will be found of special interest to those whose duty may lead them to examine into and to report upon the *healthy* condition of the heart, as, for instance, in examinations of persons for life assurance. In such cases it is often found that the mere fact of being examined by percussion and auscultation, and indeed the fact of undergoing any medical examination at all, will sometimes disturb the regularity of the heart's action, even in a perfectly healthy man; and the more especially, if as is often the case, the life assurance is sought to cover some risk or to effect some pecuniary or other personal purpose. The circumstance of having walked rather quickly, or of having eaten a meal, will often make a remarkable difference in the rhythm of the heart, and hence inquiries should be made upon these points before any examination is made, and if the heart's action should be accelerated or otherwise disturbed, it will be expedient to make the person rest for some time or to engage him in cheerful or indifferent conversation, so that the attention may be drawn off from the immediate subject of the medical interview, and the heart may return to a perfectly normal state.

The heart lies behind the sternum, and is placed obliquely in the chest, the apex pointing downwards and forwards between the fifth and sixth ribs on the left side, and the base corresponding to the space between the cartilages of the second and third ribs. The space occupied by the heart, and the manner in which it performs its functions, are determined by various kinds of physical exploration, as by the sight, by palpation, by percussion, and by auscultation.

1. On *looking* at the chest of a healthy person, it will be observed that the two sides are symmetrical, and that the apex of the heart beats at the spot just indicated. The healthy pulsations of the organ, however, are visible only in thin persons, being quite imperceptible in those who are moderately robust, and especially in those who are fat.

2. *Palpation*, or feeling by the hand, is a very important measure for ascertaining the condition of the heart. When the organ is healthy and the subject is thin, it will readily be felt to beat between the fifth and sixth ribs on the left side; when he is muscular and robust the impulse will be felt only slightly in the same position: and when the person is very fat, it will be hardly perceptible at all. The person himself is quite unconscious of the beatings of the heart, when it is in a healthy state, and it is mercifully arranged that it should be so, for if every one were sensible of each movement of the organ, continual discomfort and apprehension would ensue. In cases of exalted sensibility, however, and many forms of hypochrondriacism, not amounting to actual disease, the movements of the heart become perceptible to the individual, and what is worse, when the pulsations are intermittent, as they often are under such circumstances, each intermission is painfully self-evident. I have often felt intermittent pulses, and do not of course notice the subject to patients, but they have generally told me exactly when the intermissions occur. It is hardly necessary to state that in the great majority of cases met with in practice, intermission of the pulse is not a very important indication, and unless accompanied by other symptoms, does not deserve much attention, except so far as the fact of the patient feeling it causes him discomfort and alarm.

3. The *percussion* of the præcordial region in the healthy state gives, of course, a dull sound, but not commensurate in extent with the size of the heart, and not uniform in all cases. The heart is in fact overlapped by a portion of the left lung, and hence the dulness is more or less modified by the amount of spongy tissue by which it is partially covered. As a result of numerous observations, it is generally admitted that the natural dulness of the præcordial region extends about two inches in every direction, beginning above about the fourth rib and extending downards to the sixth, having its maximum at the centre of this region and gradually disappearing on both sides until it is lost in the lung sound. Below and on the left side the dulness is replaced by the hollow sound of the stomach, and on the right inferiorly it is sometimes continuous with the dulness of a portion of the liver.

4. By *auscultation*, either mediate or immediate, the *sounds* of the heart are heard. This mode of investigation also gives information as to the impulse of the organ, for when this latter action is increased, the stethoscope and the head of the observer are both moved; but as the hand or any other part of the body would be equally affected by this cause, the application of the ear is more especially valuable in estimating the sounds elicited by the cardiac movements. In a healthy state, these sounds are two in number, and although very easily recognised, are very difficult to express in words. Perhaps the combination of syllables *lubb dup*, as remarked by Dr. Williams, is the nearest approach to a written explanation of the sounds. These sounds follow one another, and are called respectively the first and second sounds, the first being more dull and the second more clear, and they are repeated many times in the minute, the variations in the rhythm being, of course, identical with those of the pulse felt at the wrist. The first sound is longer than the second, coinciding with the impulse of the apex of the heart against the thoracic walls, and immediately preceding the radial pulse; the second sound is clearer and shorter, and is heard after the pulsation of the arteries. As to the rhythm of the sounds, they take place in pairs, the first dull sound coinciding with the impulse of the heart, then a very short interval succeeding, during which the arteries pulsate; then comes the clear and short sound, and lastly a longer interval of rest. The relative periods occupied by this rhythmical action, supposing the whole to be divisible into three parts, would represent rather less than one third to be occupied by the first sound, one-sixth to be occupied respectively by the short interval and the second sound, and rather more than a third by the long interval of rest. Some authorities, however, divide the

whole period into four parts, about two being occupied by the first sound, one by the second sound, and one by the interval of repose; and it should be mentioned that the very short interval of rest succeeding the first sound is inappreciable when the pulse exceeds the rate of sixty in a minute. Other and more minute subdivisions of the heart's rhythm have been proposed, but they are practically unimportant. It is important to recollect that the first sound is generally called the *systolic*, being synchronous with the contraction of the ventricles, and is heard best over the apex of the heart; and the second sound is called also the *diastolic*, being synchronous with the dilatation of the ventricles, and is best heard in the middle of the sternum.

It should be very distinctly understood that the extent to which the impulse of the heart is felt, or its sounds are heard, may vary most considerably even within the limits of health in different individuals; and, moreover, it may happen that the extension of the sounds and of the impulse of the heart may be due in reality to disease of some other organs, as the lungs, the heart itself being perfectly healthy. Thus a tuberculous lung, acting as a conductor of sound and of impulse may give rise to a suspicion that the heart, which is really of normal structure, is enlarged, and on the other hand an emphysematous lung may so mask the impulse and the sounds of a diseased heart, as to lead to the erroneous conclusion that it is healthy. Again, within the limits of health, in fat subjects the sounds will be restricted within a narrower space than in persons of normal proportions; and on the other hand both the impulse and the sounds will be perceptible over a much wider extent in thin persons with a contracted thorax, in whom the sounds may often be heard at the back of the chest. The intensity of the sounds is also somewhat greater in young persons, and somewhat less in the aged.

It is impossible to insist too strongly upon the necessity of a careful consideration of all these circumstances in coming to a conclusion respecting the healthy condition of the heart.

(To be continued.)

HOSPITAL REPORTS.

VARICOCELE—OPERATION AND CURE.

(Under the care of WALTER J. COULSON, Esq., Surgeon to the Dean-street Lock Hospital, &c.)

(Continued from page 62.)

One of the ulterior consequences of a varicose condition of the veins in the leg is ulceration; and it is brought about in this manner:—owing to the venous enlargement, and to the general unhealthy condition found to obtain in the structure of the vessels, owing to the imperfection of the valvular arrangement, as well as the absence of proper tone in the adjacent tissues, there is a stasis of the blood in the part which is diseased; a lowering in the vitality of the skin, which, in consequence becomes altered in its colour and consistence, assuming a brownish glazed hue and an appearance of tension, or of great stretching, over the subjacent parts, while from the seat of this bronzing will stretch themselves large, elevated, tortuous blue lines, which are, in fact, the affected veins; the alteration in consistence is principally a loss of the natural softness and the accession of an œdematous condition, or of a brawny, leathery feel.

This being the state of the limb for some time of a longer or shorter duration, there will take place at the spot or spots where most congestion exists, and where there is most degeneration and disorganisation, an unhealthy form of ulceration; this constitutes the varicose ulcer, which, we know, is most rebellious to treatment, breaking out again and again, healing only to become again the seat of ulceration, until a thorough disorganisation of all the neighbouring tissues ensue, and a condition of chronic ulceration be induced.

Great danger is to be apprehended from the ulcerativ process, lest it eat through the coats of the vein, and giv rise to most serious, if not at times, even fatal hæmmor rhage.

We remember reading of a case, we think, in Rams botham's 'Principles and Practice of Obstetric Medicin and Surgery,' to which a medical man was hurriedly sum moned on the supposition of there being uterine hæmor rhage; relying on the representations made to him on hi entry into the sick chamber, he immediately called in D Ramsbotham, who found the cause of the flooding not i the uterus at all, but in a varicose vein, which havin suddenly burst, poured out its contents rapidly and pro fusely.

We pass now from the consideration of varix in gener to the same condition, as it specially exists in the veins c the spermatic cord.

To this has been applied the terms circocele and sper matocele, as well as the now more often used name of var cocele; its causes may be summed up among those of var in other regions; however, its greater frequency on the le side is usually explained—first, by the greater length of t left than the right spermatic vein; second, by the fact that t vein on that side opens at right angles into the renal vei instead of running along with its course for some distance, a then opening in such a manner, as that the blood of the tw should not clash, but flow on equally and in an undisturbe manner; third, a natural tortuosity of the vein; fourth the accumulation of feculent material in the sigmoid flexur of the colon, whereby pressure upon the vein accrue stasis of the blood below the point of compression and al the ulterior results of the varicose condition, which ha been induced; fifth, traction upon the left ring, where is the emergence of the vein in question; this traction is dependent upon the more frequent use of the right arm and hand, of, in fact, all the muscles of the right side, and creates a not infrequent constriction, or tensing of the ring in which action the vein has the circulation of the bloo arrested; sixth, it has been noticed, we believe, by M Curling, that this affection is of more common occurren in sailors, or ships' apprentices, than perhaps in any oth class; and this frequency is attempted to be explained b the hypothesis that the hard "ship biscuit" passed throug the stomach and through the bowels in a very impe fect state of digestion, becomes lodged, or even impacte in the sigmoid flexure, where it behaves itself as the ori mali; seventh, as causes of varicocele in either side of t scrotum, we may mention masturbation and excessi venereal indulgences; but, perhaps, more especially t former. The modus operandi is as follows:—By t frequent and unnatural determination of blood to t generative organs, these are rendered morbidly exci ble and irritable; frequent erections, at first co plete, subsequently, from a kind of atony of the geni system, only partial, supervene; the veins by this too-co stant filling are overstretched, a species of paralysis, or, speak more correctly, an adynamic condition of their tuni is the result, and the vascular walls, yielding to the dow ward pressure, occasioned by the gravitation of the colu of blood, assume a permanently varicose appearance; mo over, the scrotum becomes relaxed, and fails in its office supporting and tricing up the testicle and its veins, beca the "dartos" and the fibres of the cremaster muscle pa cipate in the adynamic condition; eighth, spermatorrh besides being a source, is very frequently an issue of complaint; ninth, youth may be considered as givin predisposition, especially if the habits be sedentary.

As we are passing the subject in review, we may l mention, that in cases of double varicocele, the lef usually the worse; very seldom are the veins of the r side affected, *per se*, and when they are in the dise condition, those of the left will be found participators.

As an exception to the rule, that in the double form the complaint, the left is the side more implicated, Erichsen states, "I have in one or two instances seen veins of the right side form the larger tumour."

Symptoms.—The patient complains of pain of a neur character, not often very acute, in the testicle, scrot

ins, down along the thighs, in the groins, and up along the course of the cord; this will be sometimes exacerbated, especially if the person take any undue amount of exercise; —of great mental depression, particularly if the affection be complicated with generative debility. Besides these, we will find, on manual examination, a cone-shaped tumour, extending in the direction of, and along with the cord, having its apex directed upwards toward the external abdominal ring, while its base rests upon the testicle; this tumour, formed by the dilated, thickened, tortuous, and elongated veins, is knotted and irregular in its outline, becomes increased in size, when the patient assumes the upright attitude, or employs himself in any way which tends to contract the calibre of the ring, through which the veins emerge into the scrotum; in the horizontal posture, the tumour will entirely or almost entirely disappear.

Treatment.—This may be either the palliative or the radical. In the early stages of the complaint, that is, when the veins alone are engaged, and there has not arisen debility of the generative organs, we should resort to the former, as being in numberless instances sufficient for all practical purposes; it is, in fact, in the severer forms of the affection alone, that we must put into execution the latter. The palliative treatment is very simple. The general health, if it have fallen below par, must be restored and braced up by tonic medicines, and by those other means accustomed to be prescribed for such a deterioration, the bowels should be most carefully regulated, and never be allowed to become constipated. The best general tonic in these cases is *some one or other* of the different preparations of iron, *inasmuch as it* exercises not only a general, but also a local *tonic action*. The scrotum and testes should be enveloped in, and supported by, an elastic suspensory bandage, or the pendulous scrotum may, according to the plan of Wormald, have its lower portion drawn through a ring of some soft metal, or have, as was recommended by Sir A. Cooper, a portion of it cut away inferiorly, so as to reduce its capacity, and relieve the testicle, as well as the veins themselves, of the weight of the column of blood.

Mr. Curling having observed the infrequency of this affection in persons wearing a truss for the inguinal forms of hernia, suggested pressure to be applied in the same manner, and at the same spot for the palliation or haply even the cure of the varicocele.

In some instances the results have been most felicitous.

Nor must we neglect the use of the cold douche to the parts, nor the application of cold astringent lotions; some have employed blisters and other counter-irritants, with a view to the excitation of an amount of inflammation in the scrotum which would cause its contraction.

The permanent or radical cure has for its object the inducing of local phlebitis, and, as a consequence, the obliteration of the veins.

For its attainment, setons have been passed through the veins, or they have been obliterated by means of caustics, applied to the scrotum.

Mr. Erichsen, in the following words, describes the operations which he practises:—"I separate the vas in the usual way, and then make a small incision, about half an inch long, in the front and back of the scrotum, afterwards I pass a needle armed with silver wire between the vas and the vein, bringing it out behind, and then return the needle, but this time carrying it in front, between the veins and the skin, and so including the veins in a loop of wire, *without* implicating the scrotum. The loop is then tightly twisted together, so as to constrict the enclosed vessels.

M. VELPEAU AT THE ACADEMY OF SCIENCES OF PARIS.—This eminent surgeon has just vacated the President's chair of this Academy, and it redounds in no small degree to the honour of the Profession that such an eminent post has been held and so worthily occupied by M. Velpeau. M. Velpeau delivered, before leaving the chair, a most appropriate and touching speech, in which he especially dwelt on the fact of having started from the humble ranks of life, and having at last obtained the envied honour of presiding, for one year, over the Academy of Sciences of Paris.

THE STATE OF THE PROFESSION IN AMERICA.

[The following letter is written to the Editor of the 'American Medical Times,' and shows that if things are bad in the old world, they are not much better in the new.]

SIR,—A week spent in an interior city of this State during the past summer, suggested the present communication. The city alluded to is situated about the centre of the State, contains a population of over twenty thousand, is one of the oldest, and reputed one of the wealthiest in the Empire State. In visiting such a place I certainly anticipated finding something of professional interest, and witnessing the successful treatment of some of those local affections, which are usually objects of interest to the physician residing in some other section of country. But though the summer was, as I was informed there, one of more than usual sickness, I came away without learning anything of interest. The prevailing epidemic at the time was a very severe form of putrid sore throat, universally styled diphtheria. In the treatment of the subsequent general prostration of such cases, I found the pyrophosphate of iron extolled by some as one of the latest and most valuable discoveries of science, and even this, though now so long in successful use, was entirely unknown to several.

From such a visit I have certainly nothing new to communicate, but I wish to make a few remarks on what I suppose to be the prominent causes of such backwardness in this age of professional and scientific progress.

First, I would notice the want of social and professional intercourse amongst practitioners. There were some twenty or more regular practising physicians, well educated, though I cannot say well read, for their education was all of the past, whilst their reading of the later discoveries in science and practice was of the most limited kind. In a few offices I found the *Medical Times*, in still fewer the *Lancet*, while many were wholly strangers to any of the medical publications of the day. With such a large number of physicians there was no professional society, where an interchange of ideas and experience would create and sustain that taste for investigation and study so necessary to success. Success, in the more contracted sense of the word, pecuniary, is, it must be admitted, attained in some isolated cases by the most ignorant pretenders. Yet success generally and professional reputation (the dearest object of a well educated physician's ambition) is only attained by unrelenting study. Besides, all agree that there is no profession more slavish or trying than that of medicine when pursued merely as a means of living. The clerk in a store with a fixed salary, or even the daily labourer, whose work ends at six o'clock, may well be envied by the practising physician, who toils both bodily and mentally for a precarious subsistence, from early morning until late at night, and is then subject to the call of any or every one from night to morning, if his profsssion is not endeared to him by some higher aim and his labour lightened by scientific thought. Much as we may be given to study, when fresh from college, most men will gradually relax their reading and lose that state, when surrounded by the sterner duties and struggles of life, if not encouraged by the interchange of thought and stimulated by intercourse with others of similar tastes and acquirements. In a city such as that of which I am now speaking, a society, meeting once a week, or even once a month, is more needed amid the drudgery of medical practice than in any other profession in life. It not only excites an interest for the time, but also creates, not simply a taste but a necessity for more liberal reading. Another local peculiarity, which seemed rather strange, was that physicians all kept a large stock of medicines in their offices, and invariably supplied their patients, at the rates of twenty-five or fifty cents,

according to the quantity of pills or powders dealt out. This certainly is reducing the profession to the position of mere pill venders, and was rather a humiliating sight. A great part of the physician's time in his office was spent, not in reading, but in compounding nostrums (for in many cases they deserved no other name), but which were ultimately sent out in the crudest forms. On expressing surprise at a medical man's wasting his time in this way instead of sending his prescription to the apothecary, various reasons were assigned. Some said they could not change from the old system, without a loss of practice. Still they confessed that in many cases they never got paid for either advice or medicine. Others said that there were no apothecaries in the city capable of compounding their prescriptions. This led me to inquire into the state of pharmacy in this place. And while I found it backward, as might be expected from the foregoing causes, it compared favorably with the sister profession. On the principal street there were some eight or ten establishments for the sale of drugs, paints, groceries, and what not. In two of them I found the proprietors graduates of pharmaceutical colleges. One had but lately arrived there, and was so thoroughly disgusted with the position of his profession that he was anxious to leave the town. The other displayed in his store diplomas worthy of a better location; and both agreed that cheapness was the only means of securing the patronage of their physicians. It is not surprising that the profession of that city was quite unsuccessful in the treatment of disease, and that most of the practitioners were decidediy sceptical as to the efficacy of their remedies. They never reflected that they could not expect much from medicines kept for months on the apothecaries' shelves, and still longer in their own offices.

Cannot suggestions through your columns lead to the formation of medical societies in all cities? I have no doubt, results would in time follow conducive not only to the immediate benefit of those joining such societies, but also elevating the general status of the profession.

REVIEW OF BOOKS.

A Practical Treatise on the Diseases and Infirmities of Advanced Life. By Daniel Maclachlan, M.D., Fellow of the Royal College of Physicians of London, late Physician and Principal Medical Officer to Chelsea Hospital, &c. London: Churchill and Sons. 1863.

Dr. Maclachlan's long connection with Chelsea Hospital, which contains upwards of five hundred aged persons, has afforded him ample means of investigating and treating the diseases of advanced life; and the bulky volume, the contents of which we now propose to analyse, affords abundant evidence that he has not neglected his opportunities.

The whole work is composed of nine Parts, of which the first is "Introductory," and includes three chapters on —1, The Anatomy, Physiology, and Psychology of Advanced Life; 2, The Diseases incident to Advanced Life, and their Remedial and Preventive Treatment; and, 3, Climacteric Disease. This portion of the book might, with advantage, have been reduced to at least one-half of its present size. The practical Medical man, for whose benefit the work is solely intended (see Preface, p. x), does not care for the descriptions of old age, however faithful they may be, which have been left us by Crates, an ancient comic poet, Cicero, the British Essayists, and Sharon Turner; nor is he encouraged to study the subject of senile dementia, when he meets with so flowery an introductory sentence as the following:

"All flesh is grass; but thus the immortal portion of our nature asserts its independence, and long outlives the decay that surrounds it."

Intermingled, however, with the superfluous matter is much sound and valuable information. Everyone who has paid much attention to the diseases of old age, will recognise the truth of the following observations regarding the special difficulties of their diagnosis:

"The accurate discrimination of disease in advanced life is not always a matter of easy attainment. This difficulty partly arises from the complicated nature of disease at this period several diseases, of more or less importance, and of longer or shorter duration; frequently co-existing, and blending their respective symptoms or masking them. The gradual failure and modification of the different functions also vary the phenomena of disease. Thus the declining irritability of the nervous system hinders the development of some local symptoms, and influences the character of the constitutional reaction, if it does not entirely prevent it. Those remarkable sympathies between distant or contiguous organs, that aid the practitioner in forming a correct diagnosis, cease altogether, or are much less constant and intense, particularly in extreme old age. Vomiting is less generally present in disease of the brain, liver, or kidneys, than in the adult; it is even often entirely absent in organic disease of the stomach itself. Inflammatory attacks of diarrhœa having their seat in the large intestine, and to which old people are prone, are seen coinciding with an almost natural state of the system, and without any symptom of suffering in the superior part of the digestive tube. The kidneys, also, are frequently extensively diseased with little urinary distress; and the bladder, deprived of its former irritability, is sometimes distended to bursting without the usual agony. Inflammation seems to paralyse sensation, and pain is often entirely wanting in many diseases, which, at other periods of life, are accompanied with it in a high degree. Pleuritis, and still more frequently, pericarditis, even when associated with the disease, again and again proceed to a fatal termination without it, and yet, on post-mortem examination, we find indubitable evidence of the inflammation having been of the most intense form. The isolation of the different organs in disease is one of the most remarkable phenomena in the pathology of advanced life, and the frequency of latent maladies of the most dangerous character ought never to be lost sight of." (Pp. 35, 36.)

Very similar remarks have been previously made by other writers, but the subject is one of such practical importance that we feel we need offer no apology for introducing it in the lucid form in which Dr. Maclachlan has placed it.

Our author's remarks on blood-letting and on the administration of purgatives, mercurials, antimonials, emetics, narcotics, diuretics, and tonics, although containing little novelty, are sound and trustworthy, and are deserving of careful perusal.

The "Second Part" treats of the Diseases of the Nervous System—viz., meningitis, acute and chronic serous hydrocephalus, vertigo, epilepsy, apoplexy, softening of the brain, and paralysis. In his remarks on vertigo the author records the following singular case:—"A colonel in the army whom I have attended on several occasions for attacks of congestive headache, and who is very liable to giddiness on the least derangement of the stomach, is almost sure however well he may be, to be seized with it if he walk upon asphalt. He is thus obliged to avoid certain parts of London, often to his great inconvenience. This is no fancy, as he has frequently been attacked when previously quite unaware of the nature of the pavement. It is singular that he can walk upon snow or sand without suffering."—(p. 102.)

In the treatment of vertigo, the first question to consider is whether plethora or anæmia of the brain is present. In the former case depletory measures must be adopted, while in the latter a tonic and restorative treatment is demanded. We fully concur in the author's view that the vast majority of cases of vertigo in advanced life belong to the second category.

The following remarks on the action of various remedies in paraplegia will be read with interest as showing how little this affection is under the control of medicine:—

"Benefit is occasionally derived from the exhibition of nux vomica, or its active principles, strichnia (*sic*), or brucia in the advanced stages of the primary form of

disease. These alkaloids appear to have more influence in paraplegia than in hemiplegia or other kinds of paralysis; but, upon the whole, their efficacy is in the vast majority of cases at least doubtful, and without extreme caution they often prove injurious. The arnica montana and rhus toxicondendron (*sic*), both of which at one time enjoyed considerable reputation in this and other forms of paralysis, are fast falling into disuse. From the tincture of cantharadis (*sic*) administered in doses of ten or fifteen drops three times daily, I have seen some good results, and this remedy is deserving of trial. The ergot of rye is another drug which has been praised in paraplegia. Faradisation, lately introduced, seems to give good promise."—(p. 208.)

The third part treating of "The Diseases of the Respiratory Organs," extends over about 150 pages. In his remarks on the Treatment of Acute Bronchitis by emetics, Dr. Maclachlan states that in cases of extreme prostration, he employs vinum ipecac. We are surprised that he makes no reference to sulphate of zinc, which has been highly commended in this disease, and is in many instances preferable to ipecacuanha. Excepting for this comparatively trifling omission, his directions regarding the treatment of acute bronchitis indicate that he has carefully studied the different phases of this disease. In his remarks on the treatment of chronic bronchitis he observes that "half a grain of codeia given at bed-time is occasionally most soothing and successful in producing sleep when other hypnotics fail." Such opposite opinions are held regarding the energy and inertness of this preparation that we shall be obliged if any of our readers who have tried it will communicate the result of their experience. In a case of sleeplessness in which we lately tried it, doses gradually increased from half a grain to a grain and a half produced no appreciable effect, while 20 minims of tincture of Indian hemp seldom fail to procure a fair night's rest; and we recently heard of a case in which a young lady accidentally took five grains of codeia in place of the half grain that had been prescribed for her, and which she had been taking for some time; and the only result was that she slept much as usual.

The chapter on pneumonia is in our opinion far too elaborate. We very much prefer the author's personal observations to the numerous quotations from Andral, Laennec, Grisolle, &c., which he has inserted; and we do not want the opinions "of such men as Chomel, Williams, Hourmann and Dechambre, Canstatt, and other equally eminent physicians, whose names do not occur to me at present," (p. 310) to satisfy one's self of the soundness of Dr. Maclachlan's views on the much vexed question of venesection in pneumonia. "Although (he observes) I have recommended bleeding in sthenic pneumonia occurring in vigorous constitutions irrespective of age, still I feel bound to observe that the cases requiring and admitting it are in reality few. Occasionally a succession of cases occur in which bleeding appears to be imperatively demanded; but, on the other hand, still more frequently, we dare not bleed. Of late years these cases have been increasing. A low form of pneumonia, not exactly of an adynamic type, is more common than it used to be, and for one case now suited to bleeding, we meet with at least a dozen that would be injured by it. In the autumn of 1860 and winter of 1860-61, out of at least twenty cases I have not once bled or felt called upon to bleed." (p. 311.)

In the Fourth Part, "the Diseases of the Organs of Circulation," are considered. Acute diseases of the heart—pericarditis and endocarditis—are less common in advanced life than during the earlier periods of existence, but on the other hand it is in old age that we most frequently meet with chronic changes of the orifices, valves, and walls of the heart. "Calcareous depositions on the valves, cancerous degeneration, primary and secondary, softening and fatty degeneration of the muscular structure, partial aneurisms and rupture of the heart itself, are almost peculiarly diseases and accidents of old persons; whilst it is in them that we most frequently encounter that still obscure but singularly severe and interesting malady depending apparently upon a variety of organic and accidental causes, long known under the name of angina pectoris."—P. 395. But although large numbers of old people are carried off by disease of the heart, "still the prognosis is on the whole more favourable in the aged than in the adult. We do not look for cure where the valves are changed in structure, the orifices dilated or contracted, or where the walls and cavities are altered; but organic disease of the heart in advanced life is almost always of slow growth, sometimes stationary, and many years often elapse ere it tells upon the system or affects particular organs. Old age brings with it an amount of security which is not the lot of the young; and not unfrequently the lesions which in youth would be accompanied with continued suffering, are now, owing to their passive nature, the diminished activity of the organism, and a blunted susceptibility, less severe in their consequences. Simple enlargement of the heart, with or without diseases of the aortic valves or aorta itself, is not inconsistent with the prolongation of life to advanced old age."—Page 405. These views, although containing nothing essentially new, are clearly illustrated by several cases of which our author has given the details. In one of the instances recorded, there was reason to believe that obstructive valvular disease of the aorta had existed for about twenty years, and in another case, that of a general officer, now eighty years of age, "there is a permanent rasping bruit with the first sound at the base of the heart distinctly heard several inches up the sternum. To my knowledge this murmur has existed seven years. His former medical attendant had accidentally discovered it five or six years before; yet he enjoys perfect health, has never had dyspnœa, and is capable of walking several miles without discomfort or fatigue."

Our limited space will not allow of our entering into any detailed notice of the five remaining parts, which treat respectively of "The Diseases of the Digestive Organs," "The Diseases of the Biliary Organs," "The Diseases of the Urinary Organs," "The Skin and its Diseases," and "Constitutional or Blood-Diseases." Most of the subjects are discussed in a sound practical manner, and we would especially recommend to the perusal of our readers, Dr. Maclachlan's remarks on "Chronic Enlargement of the Prostate Gland," and on the various forms of gout.

While we heartily thank our author for his valuable contribution to our medical literature, we must at the same time express our decided opinion that he would have acted more wisely if he had condensed his bulky volume to about one half of its present size, and this might have been readily done without any interference with its practical utility. What we and the medical profession generally would like to know is not what Canstatt, Prus, Durand-Fardel, and others have written on the subject, but what Dr. Maclachlan has observed for himself in the wide field of clinical observation which Chelsea Hospital has afforded him for nearly a quarter of a century. When a new edition is called for, which we trust will be the case in due time, we would advise the author to correct his own proof-sheets. This he has obviously not done on the present occasion, for we are sure that no Fellow of the Royal College of Physicians of London, could have failed to detect at a glance, such atrocious misprints as the following:—enemeta (pp. 511, 521, 645), scybalæ (pp. 485, 505), tincture of cantharadis (p. 208), acetum cantharides (p. 632), lininentum suponis (p. 662), prima viæ (p. 642), anœmic (p. 411), fætidus and fætid (pp. 430, 535), and edentalous (p. 710), and yet these are all to be found "*sic in origino*" (p. 554.) Whether the printer's accuracy or our own intelligence is at fault in the following cases we are not sure; but we must confess that we have no clear view regarding the composition of "the sulphurus potassæ" (p. 643), or as to the nature of the "deotised" condition of the urine in old age (p. 590).

INSPECTOR OF ALKALI WORKS.—The Committee of Privy Council for Trade have appointed Robert Angus Smith, M.D., F.R.S., F.C.S., to be the Inspector of Alkali Works, in conformity with the provisions of the 26 and 27 Vict., c. 124.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Mr. PRESCOTT HEWETT, President.

Dr. WILKS showed the

SUPRA-RENAL CAPSULES FROM A PATIENT WHO DIED OF MORBUS ADDISONII.

These organs presented the usual appearances seen in morbus Addisonii, and came from a girl who was under Dr. Wilks' care in Guy's Hospital, and who presented a model case of the disease. She was 23 years of age, and for two years had suffered from discoloration of the skin, debility, some wasting, and occasional sickness, the sickness being at times worse. She sought the assistance of Medical men. She had seen several, and they all considered the case as one of liver disease. This mistake (Dr. Wilks says) should not have been made, seeing that her eye was not yellow, nor her urine jaundiced. When she came to the hospital her skin was of a greenish-brown colour, like that of a native of the south of Europe ; she did not appear very ill, judging from her expression, but was so weak that she was obliged to be carried to bed ; she also had sickness. The latter abated, and she felt much better, so that indeed she was the merriest person in the ward. She was, however, at this time so weak, that she could not sit up in bed, and her pulse was like a thread. Wishing to leave the hospital at Christmas time, she went home, Dr. Wilks requesting that he should be informed when she became worse. Only a few days elapsed when he was sent for, and found her in a dying state. She was quite sensible, and able to speak, but was utterly powerless, and her pulse could not be felt. She had been lying in this state for twenty-four hours, and in the course of the night she died. Dr. Wilks said the case was so marked that he invited several Medical men to see it, and took one of her Medical attendants with him, to perform the post-mortem examination. No disease was found in any part of the body, except in the supra-renal capsules, which were converted into a yellow, amorphous material, with some cretaceous deposit. Dr. Wilks remarked that several attempts had been made to investigate the subject of Addison's disease, by an examination of the supra-renal capsules in all bodies. He had done this for many years himself, and like Professor Mattei, of Siena, but his observations had been unattended with success. The reason seemed to be, that, if affected by any other disease than the special one, they were only partially or rapidly involved in some disease which infected the whole body, as cancer or tubercle; whereas, in morbus Addisonii, the change was a primary one, and altogether independent, pursuing its course for several years, and, probably, totally destoying the organ a long time before death. It was for this reason that the author of the discovery did not look upon the supra-renal capsules as vital organs, but which, when diseased, produced the remarkable asthenia by implication of the centres of the ganglionic system, which were closely contiguous.

THREE CASES OF MORBUS ADDISONII.

Dr. WILKES also exhibited some supra-renal capsules affected in a similar manner, and which had been sent to him by Dr. Hardwick, of Leeds, since deceased. The patient was a man, 29 years of age. For some time he had pain in the back and leg, and, about nine months before his death, his companions noticed his skin becoming yellow, and they thought he was going to have jaundice. He got weaker, and the skin became darker, and the urine was always pale. He got a little better under treatment, when he had an epileptic fit, and subsequently he had vomiting and slight convulsive movements. He was then so feeble that he was obliged to be carried to the infirmary. His body was of a dirty olive-brown tint, giving him a close resemblance to a mulatto. He also had a psoas and lumbar abscess. His depression gradually increased until death. There was found disease of the lumbar vertebræ, and the supra-renal capsules were converted into a dense, tough, fibrous mass, with some cheesy, tuberculous matter. Dr. Hardwick stated in his communication, that since he had been connected with the Leeds Infirmary he had seen four other cases of morbus Addisonii besides the one just related. In two of them, although the symptoms were well-marked, the cases were not followed to their termination. In the other two—one was a man, 52 years of age, who had long suffered from great prostration and discoloration of the skin—death occurred by gradual sinking. No disease was found except in the capsules, which were converted into a grey, lardaceous material. The other was that of a woman, aged 69, who had great prostration, frequent vomiting, and her skin was of a dark brown colour throughout. No disease existed except in the capsules, which were filled with a mass of grey and yellow, soft, cheesy deposit. She was a patient of Dr. Hall.

Dr. HARLEY, in reply, stated, that although he had no wish to reopen the question which had given rise to so many animated discussions at their meetings a year or two ago, he could not allow some of the remarks which had fallen from the last speaker to pass unanswered. Dr. Wilks appeared to be both surprised and annoyed that pathologists of standing in Edinburgh and elsewhere still doubted the existence of the so-called Addison's disease, which he seemed to regard as a settled question. He (Dr. Harley) like Dr. Wilks, also thought that it was a settled question but differed from him in thinking that it was settled in the affirmative; for, on the contrary, the highest authorities on pathology abroad, and nearly all at home (only one or two being exceptions to the rule), had either given a *distinct* negative or left the question as very doubtful ; and no one who had carefully watched the progress of the discussion could be in the least surprised at such a result. Even the most staunch supporters of the theory of bronzed skin and supra-renal capsular disease had shifted their ground so often, and altered their views so frequently, that he for one must confess that at the present moment he had not the most distant idea of what Addison's disease consisted in. First, we were told it consisted in bronzing of the skin, and destruction of the supra-renal capsules ; next we were told that the bronzing must be universal, not in patches ; then informed that the bronzing of the skin only occurred in the most advanced stages of the disease ; and lastly, there came a time when we were informed that the bronzing of the skin was in no way essential to the affection, its presence or absence being a point of minor importance. And now the disease seemed to have entered upon an entirely new phase of existence ; for we were just informed by the last speaker that there is only one form of diseased capsules which constitutes Addison's disease—viz. a peculiar scrofulous affection. It seems, then, that the supra-renal capsules may be totally destroyed by tubercle or any other disease except that just mentioned, and the functions utterly obliterated, without giving rise to Addison's disease. The supra-renal capsules may be one mass of cancer, and yet the disease which is said to spring from the absence of their functions not exist. It further appears from what the gentleman has just stated, that even the highest authorities on the subject have no very clear notions as to what the affections consist in ; for, be it observed, that in the present case, which has been brought before the Society as an unmistakeable example of the affection, its contributor acknowledges, that not only the resident assistants mistook it, but that even two of his colleagues failed to detect it ; and further, that it was not until he himself had subjected the patient to the closest scrutiny, that he was able to detect this well-marked example of the disease. How, then, it may be asked, can he be surprised that persons like himself (Dr. Harley) failed to recognise the so-called Addison's affection ? In truth, as believed with the German authors, some of whom have named it the "ephemeral epidemic," that it would gradually die away ; and if the supporters of the theory wished to preserve its name a little longer from utter oblivion, they must be much more careful in the selection of their cases.

and at once abandon the system of publishing cases as examples of the disease, which have not only not been seen by competent observers, but in which the capsules have not been examined at all; for several cases have actually been published while the patients were still alive. It is further necessary for them to state positively in what Addison's disease consists; for, looking at the thing as it now stood, it appeared to him that the supporters of the doctrine were themselves doubtful if either bronzing of the skin or disease of the supra-renal capsules were at all essential to the supposed malady. And if they abandoned the bronzing, and abandoned the disease of the capsules, there could be no longer an Addison's disease.

Dr. WILKS said, in reply, that although there might be a difficulty in explaining the symptoms, yet the fact of the disease being foretold in so many instances, left the truth of Addison's statements incontrovertible.

Dr. BRISTOWE was surprised to hear that Dr. Harley considered that the question as to the existence of Addison's disease had been decided in the negative. He (Dr. Bristowe) had no doubt whatever about it. He had seen patients die with the symptoms described by Dr. Addison, and had found, after death, no disease except of the supra-renal capsules.

Dr. HARLEY again asked if bronzing was an essential symptom or not?

Dr. WILKS replied that it was not absolutely essential.

Dr. HARLEY then asked if it was essential that there should be no disease of any other organ?

Dr. WILKS said, that in all the cases which he had seen, the only other disease found had been a little tubercle; but he knew of no reason why it should not be found associated with other morbid conditions.

Dr. RISDON BENNETT then related a case of Hydatid Disease of one Capsule. The other was healthy. There had been no bronzing of the skin, and no other symptoms of Addison's disease. But in two other cases, Addison's disease was diagnosed during life, and, after death, the capsules were found to be diseased.

MALFORMATION OF THE GENITAL ORGANS.

Mr PARTRIDGE exhibited a patient, fifty years of age, with deficiency of the lower wall of the urethra from the external meatus to the scrotum.

A report was read by Mr. Bryant on Mr. Brooke's case of Tumour of the Breast, showing it to be an example of colloid cancer.

COLLOID CANCER OF OVARIES (?)

Dr. J. POLLOCK showed this case, giving some interesting details respecting it, with a view of ascertaining whether it was really a case of the disease the name of which he had attached to it.

Dr. WILKS observed that it had the appearance of adenocele.

Mr. HULKE was requested to report on this specimen.

RUPTURE OF THE AORTA.

Mr. SIBLEY exhibited the specimen, showing a rupture through three parts of the circumference of the vessl. It caused death within a few seconds after feeling sick and faint. No pre-existing signs of any such disease had been observed.

HEMORRHAGE INTO THE CEREBELLUM.

Dr. BROADBENT showed this from a young girl. She was sixteen years old, and apparently in good health previously; was found suddenly attacked with sickness and pain in the head; within an hour coma and death occurred. The uterus and ovaries were also shown. A large Graafian vesicle existed. Some blood was seen on the surface of the uterus. Menstruation occurred three weeks before death.

APPENDIX EPIPLOICA IN A HERNIAL SAC.

Mr. COOPER FORSTER showed this from the body of a man who died in Guy's Hospital after operation for hernia. The appendix epiploica was found in the sac, which had the exact appearance of a testicle and cord, and might easily be mistaken for such by an operator.

DEFICIENCY OF ABDOMINAL PARIETES.

Dr. BRODIE showed a child born recently, exhibiting this deficiency, and dying after forty-eight hours. A thin membrane existed throughout the entire anterior surface of the abdomen, and formed a protruding sac, containing most of the viscera. There was an aperture existing between the abdomen and chest. One kidney was a mass of cysts. The recti muscles existed and diverged, one on each side of the sac.

SPINA BIFIDA.

Mr. CALLENDER presented a fœtal specimen, showing fissure throughout the track of the spine, the details of which he described.

In answer to Mr. Hulke, Mr. Callender had been unable to examine the fluid of the tumour.

PARTS AFTER EXCISION OF ELBOW.

Mr. CALLENDER showed these from a girl ten months after the operation in one of our large provincial hospitals, where she had been well taken care of. Three months ago she was admitted into St. Bartholomew's Hospital, with no use whatever of the limb, which was colder than the other. After long attempts to improve this condition, the limb was removed. The muscles were in fair condition, and their new connections were carefully described. The line of the ulnar nerve was lost in the fibrous tissue existing at the site of the wound. No direct connection between the osseous surfaces existed. Mr. Callender also showed the splint used at the hospital for these cases. He remarked on the most desirable period for applying passive motion in these cases.

Mr. BARWELL and Mr. HOLMES coincided in thinking that the ulnar nerve had been divided in this case.

Mr. HULKE thought, with Mr. Holmes, that passive movements should be commenced early.

Mr. WOOD and others took part in a conversation on this subject.

The PRESIDENT reminded the members that the division of the ulnar nerve would only paralyse two of the muscles of the forearm.

Dr. GIBB showed a diagram of the larynx in a case of

FUNCTIONAL APHONIA OF TEN YEARS' DURATION,*

occurring in a married lady, aged fifty-two, and arising gradually (not suddenly) in the first instance from emotional causes. She had undergone various plans of treatment, without any results, except on one occasion for about three weeks in the early part of 1862, when a harsh, rough, masculine sound appeared, and then went away. This was about eighteen months before Dr. Gibb saw her. He found paralysis of the vocal cords present, with complete immobility, both cords running perfectly parallel for the greater part of their length, and then meeting at their point of origin. This parallelism and the form of the glottis were accurately represented in the diagram from a sketch made at the time of the examination. The width of the glottis was about two lines, and respiration was performed without in any way altering it. As almost everything had been tried in vain, including galvanism to the cords, reliance was placed chiefly upon silver showers to the larynx. This treatment was followed by the best results; for the natural voice returned in good power and compass in the course of a few days, and has continued after a ten years' absence.

Dr. Johnson, Dr. Quain, Mr. T. Smith, and Dr. Broadbent made some remarks on this case.

(Continued at page 91.)

* If our readers will turn to page 4 of the MEDICAL CIRCULAR they will find this case related by Dr. Yearsley; and as we have had indubitable proof of the correctness of that gentleman's narration, we would advise Dr. Gibb to be a little more sure of his facts. The lady had been treated at the latter end of 1862, and not "in the early part." Instead of "a harsh, rough, masculine sound," her voice was perfectly natural, with occasional hoarseness, so says the husband in his letter of thanks to Dr. Yearsley. Instead of retaining it only "three weeks," it remained with her for *six weeks*. Then, *as now*, she sometimes lost it for half an hour at a time. We shall be happy to insert any explanation by Dr. Gibb of the discrepancies in these statements between himself and Dr. Yearsley.

THE MEDICAL CIRCULAR.

WEDNESDAY, FEBRUARY 3, 1864.

THE BRITISH PHARMACOPŒIA.

The British Pharmacopœia is now in the hands of the Profession, or at least, it may be for the consideration of 10s. 6d. paid for each copy; and as the alterations in pharmacy effected by this volume will be binding, both on the Medical Profession and on the pharmaceutical body, we only supply a necessary want in giving to our readers every information in our power, as to the changes which have occurred, whether in the introduction of new medicines, the omission of old ones, the nomenclature of the articles employed, or the methods of weighing them.

While the proof-sheets of the volume were passing through the press, we thought it our duty to abstain from making any comments on the nature of the work, but as soon as the book was presented to the members of the Medical Council, we broke the silence which we had hitherto imposed upon ourselves, and immediately laid before our readers the prominent features of the new Pharmacopœia, and our last two numbers will be found to contain a great amount of condensed information on this important topic. The subject, however, is of such paramount interest that we offer no excuse for recurring to it, and we shall from time to time continue to lay all the particulars before our readers, with such comments as the circumstances may suggest.

The difficulties of arranging the British Pharmacopœia, and reducing it to its present shape, have no doubt been very great, as every one can well understand, who knows how hard it is to overcome national or individual prejudices, even on trivial matters. When it is remembered that the three Pharmacopœias of London, Dublin, and Edinburgh, differed most materially in the selection of the drugs themselves, in the mode of preparing them, and in weighing them for administration, it will be easily understood that the Pharmacopœia Committee had an Herculean task before them, to reconcile these conflicting elements, and to harmonise discordant views. In this scientific contest, it is but too evident that the London section has had the worst of it, and that many of the best features of the last London Pharmacopœia have been abandoned, while many innovations, of very questionable value, have been introduced. The fact is, we understand, that the representatives of the London College of Physicians were constantly outvoted by those of the Edinburgh and Dublin Colleges, and the consequence has been that the Scotch and Irish elements enter in somewhat preponderating proportion into the new work.

This result is especially remarkable in the alteration of the weights; a change of such great importance, and one which will occasion so much inconvenience, that it cannot be too fully explained with a view to its general comprehension, if not general acceptance. It is well known that there are two systems of weights in use in England: one the avoirdupois weight, by which all the usual articles c commerce are weighed, and the other, the troy or apothe caries' weight, by which gold and silver, and medicines are weighed. Now, although this diversity of weights wa by no means a philosophical arrangement, yet, like som other anomalies, it worked well, and no one, in England a least, ever complained of its inconvenience. The avoirdu pois pound was divided into sixteen ounces, and the tro pound into twelve, and the ounce of the latter was sul divided into eight drachms to each ounce, three scruples t each drachm, and twenty grains to each scruple. But th reconcilement between the avoirdupois pound and the tro pound was incompatible with the division into drachm and scruples, representing integral numbers of grains; fo the avoirdupois pound consists of 7,000 grains, and th sixteenth of this number is 437·5, which is the actua number of grains in the avoirdupois ounce, instead o 480 grains, the present complement of the troy ounce When the number 437·5 is sub-divided into eight parts and each of these eight parts into three, it is evident tha a number of inconvenient fractions must be the result and hence it was necessary either to alter the value of th grain, or to abandon altogether the use of the drachm and the scruple. It was, therefore, proposed by Dr. Charles Wilson, the Secretary of the Edinburgh section of the Pharmacopœia, to alter the value of the grain weight, so as to make integers of the ounces, drachms, and scruples, bu making the grain a fractional part of the present grain Very little inconvenience would have resulted from th change, but nevertheless the proposition met with so muc resistance, that it was eventually determined to preser the integral number 1 for the grain, although this step i volved the necessity of making fractions of the ounc drachm, and scruple. Such is, therefore, the prese arrangement, and the ounce contains, as we have stat 437·5 grains, while the drachm and the scruple, as be expressed by inconvenient fractions, are to be abandon altogether.

When we ask ourselves what advantage has been obtain by this change, the answer must be that it is very sma if any, while the inconveniences are pressing and manife The chemist and druggist will use the same weights dispensing opium and calomel, as the grocer does for sug or the butcher for meat; but the Medical practitioner, w does not weigh sugar or meat for purposes of trade, will debarred from prescribing scruples and drachms, which h hitherto been most usefully employed in the administrat and dispensing of medicines. Another advantage, if s it can be called, is that the ounce measure of water weigh exactly an ounce; but as no one cares much practice whether it does so or not, the benefit is material, more especially when we recollect that this applies only to water, and to no other fluid, and onl water at the temperature of 62 deg.

With regard to the names of the medicines used, it be necessary for the Medical practitioner to forget chemi altogether, so far as the nomenclature of the Materia Me

is concerned. The restoration of the old and familiar names to many of the drugs, is by no means an objectionable step, and is calculated to prevent mistakes, both in prescribing and dispensing, especially at a time when chemical theories are frequently changing, and when the names of chemical compounds change with the theories. But if this system is adopted in some cases, why is it not adopted in all? and why designate our old acquaintance, cream of tartar, which has lately been known as bitartrate of potash, by the still more recent name of acid tartrate of potash? We are fully aware of the chemical reasonings which render the latter name theoretically correct, but as chemical theories are ignored in the new nomenclature, why make this exception to the rule?

The expurgation of articles contained in the last London Pharmacopœia has been effected with no sparing hand, and we have but little to say in favour of many of the banished drugs, most of which we can very well do without. But if we have lost marsh-mallows, wormwood, canella, quinces, black and white hellebore, lettuce, arrow-root, pellitory of Spain, tormentilla, violets, buckthorn, sagapenum, stavesacre, and many other dangerous or useless articles, we may well ask whether the acquisitions in the new Pharmacopœia are such as to give general satisfaction. Cocculus indicus, a most dangerous poison, said to be used by some brewers for the adulteration of beer, but of no earthly value, so far as we are aware, in the practice of medicine, is one of our new acquisitions. Its only use, we believe, is in the form of external application for the destruction of lice, in which operation staveacre is quite as efficient, but neither of them possessing more efficacy than several other preparations. Why, again, is Arnica introduced? unless it be to throw a sop to the homœopathic fraternity, who profess to find in this drug an amount of efficacy which the rest of the world have failed to discover.

As we were present at the lecture given last week by Dr. Garrod, on the British Pharmacopœia, at the College of Physicians, we were anxious to learn what the Lecturer, himself one of the *collaborateurs* in the production of the work, thought of this plant, which we know is so loudly extolled in some quarters, being considered "the sovereign'st thing on earth, like parmacity for an inward bruise." We were not by any means surprised to learn from him that, as far as it could be ascertained by experiment, the drug possessed no efficacy at all. Bruises made in the operation of cupping on both sides of certain patients, were treated respectively with tincture of arnica and with rectified spirit only, and the results were precisely the same. Bruises which were left to themselves also did well, but the discoloration did not disappear so rapidly as when spirit was employed, thus proving the advantage of using spirit lotions, or brandy and water in such cases. As for arnica, however, used externally or internally, it appears to possess hardly any active powers whatever.

These observations are offered upon some of the striking features of the work now presented to the Profession, and we shall pursue the subject in future numbers.

PUBLICATION OF THE BRITISH PHARMACOPŒIA.

The following notice appears in the 'London Gazette' of January 26, 1864:

Notice is hereby given, that the 'British Pharmacopœia' has been published, under the direction of the General Council of Medical Education and Registration of the United Kingdom, and that the same has been printed by Messrs. Spottiswoode and Company, of New-street square, in the City of London, Printers, under the authority of the said Council.

Dated the 25th day of January, 1864.

FRANCIS HAWKINS,
Registrar of the General Council.

SUMMARY OF THE WEEK.

THE MEDICAL COUNCIL IN THE COURT OF QUEEN'S BENCH.

Under our head of Legal Intelligence we have inserted the Report of an application from a Mr. Sargeant for a *mandamus* to the Medical Council to restore to the Medical Register his own name, which has been omitted in consequence of his change of residence, and has not been replaced, although he has made application for that purpose. It was very justly contended that it would be a most unwarrantable exercise of arbitrary power, to deprive a man of the power of exercising his profession, merely because he had accidentally omitted to intimate his change of abode, and we are glad, therefore, that the rule for a *mandamus* has been made absolute. In reference to this matter, however, we quote the following observations from the 'Lancet,' merely premising that the Dr. J. P. Sargeant there referred to, cannot, of course, be the same person as he who has applied for the *mandamus*.

"It is not right that this should go forth to the Profession without our reminding them that we had only a fortnight since to call attention to a beastly pamphlet with the name of 'Dr. J. P. Sargeant' pasted on the cover, and in relation to which a mendacious advertisement had appeared, falsely quoting the 'Lancet' as having given a favourable review of the filthy production."

THE RECENT ELECTION OF EXAMINER AT THE COLLEGE OF SURGEONS.

We are very sorry to learn that the late election of an Examiner at the College of Surgeons has not been altogether conducted with fairness. It was stated in what we conceived to be very respectable quarters, that Mr. Gulliver, although first on the list, had declined to allow his name to be proposed, and we accordingly copied the statement into our columns. It now turns out that Mr. Gulliver never did anything of the kind, and that he is so disgusted with the whole proceedings, that he has resigned his seat at the Council. We can only express own own great regret at having given additional currency to an unfounded rumour, and at the loss which the College must sustain by the retirement of Mr. Gulliver, whose claims to professional respect are of the highest order. To exclude such a man from the Examining Board, because he is not an Hospital Surgeon,

is an utter absurdity, and yet we believe that this is the only reason why he was not elected.

THE CASE OF GEORGE VICTOR TOWNLEY.

The attorney for the prisoner in this case has addressed a letter to the 'Times,' in which he states, in reply to the insinuation that the extraordinary result was achieved by the expenditure of money, that the magistrates who signed the Lunacy certificate, under the statute of the 3rd and 4th of Victoria, chapter 54, were only selected accidentally and as a matter of convenience, as they were on the spot where the prisoner was confined; that the two Medical gentlemen, who took part in the examination of the alleged lunatic, were selected only for their known experience in matters of lunacy, and that their services were wholly gratuitous; and that Dr. Forbes Winslow refused to enter upon an examination of the prisoner's mental condition unless he were permitted to do so, unfettered and uninfluenced by any pecuniary engagement, and that he has received no fee or reward up to the present time. Mr. Gisborne, the surgeon to the gaol, is said to have been subpœnaed by the prosecution, although he was called for the defence, and to have had, from the defence, no compensation for his services.

FALSE QUANTITIES AT THE COLLEGE OF PHYSICIANS.

While the three Colleges of Physicians are debating upon the adjustment of the weights and measures used in the Pharmacopœia, it is painful for us to state that the Royal College of Physicians of London is dealing in false quantities. This institution used formerly to pour out measures as pure as the fountain of Castalia, but, under the new *rĕgime*, the stream has become somewhat turbid, and the College displays a painful disregard to the Gradus ad Parnassum. If such laxity had been discovered in one of the *Members* of the venerable edifice in Pall Mall, the world might not have been amazed, but coming from its Fellows it is indeed unpardonable. The orator, who, last week delivered some very able discourses on the British Pharmacopœia, pronounces the word sulphurous, sulphūrous, forgetting that the penultimate syllable in the oblique cases of sulphur is short.

> "et latè circum loca sulphŭre fumant."
> VIRGIL.

and, moreover, that Shakespeare in *Hamlet* says:

> "When I to sulphŭrous and tormenting flames
> Must render up myself."

Another instance is that he pronounces one of the varieties of Pityriasis as Versicōlor, overlooking the fact that the latter word is a classical one, and that the penultima is short.

> "Astur equo fidens, et versicŏloribus armis."
> VIRGIL.

These facts, and the sad typographical errors allowed to escape notice in a book lately written by one of the Fellows of the College, and which we have reviewed in our columns of this week, ought to make the College look to its laurels. The shade of Sir Henry Halford still hovers over the establishment, and must be horrified at the decadence of classical learning within its walls.

SARRACENIA PURPUREA IN SMALL-POX.

It will be recollected that, during the last summer, w cautioned the members of the Medical Profession again giving credence to the reputed powers of the Sarraceni Purpurea in the treatment of small-pox. A very wel meaning gentleman, a surgeon in the Guards, published letter in the 'Times' containing some rather crude remarl and very hasty inductures as to the value of this plant i the disease in question, and his views, to our great surpris were indorsed by some of our Medical contemporaries, a even by the 'Lancet' and the 'Medical Times and Gazett The bubble has now burst, and America, the country fro which the history of the wonderful powers of the plant fi emanated, now repudiates its own progeny. A committ of the New York County Medical Society, after havi carefully examined the evidence on the subject has arriv at the following conclusion:

"Your Committee has endeavoured to lay before t Society the history and recorded experience thus far in t use of the Sarracenia Purpurea for the treatment of sma pox, and, in conclusion, would respectfully submit the f lowing, as their deductions from the testimony here acc mulated. 1st. That the analyses already made of the pla do not give any active principle or elements which wou indicate any great medicinal potency. 2nd. That the di coverers and advocates of the specific remedial power of t Sarracenia Purpurea over variola have given apparentl too great credit to the "post hoc" circumstances, as bein "propter hoc" influences (one reason for this latter infe ence being suggested by the loose, unscientific, and eul gistic style of the communications). And 3rd. That the liable recorded experience thus far, appears to preponder against the remedial efficiency of this plant in those for of the disease which do not generally recover under administration of ordinary remedies. Charles Hensch M.D., *Chairman*, John G. Adams, A. S. Purdy, Joseph Merritt, Joseph S. Crane."

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. I. BAKER BROWN commences a series of clin lectures on "Some Diseases of Women Remediable Operation." The present lecture is on the Diagnosis Ovarian Disease, and Mr. Brown adduces several case show the difficulty which exists during life in distinguish the different kinds of ovarian and uterine tumours. four conditions likely to be confounded together are p nancy, fibrous tumour, ascites, and encysted tumour. most common of these is, of course, pregnancy, but often mistaken for disease. Sometimes pregnancy is ciated with the existence of a fibrous tumour of the ut as in one unique case recorded by Mr. Brown; in su condition a diagnosis is impossible. Sometimes ov dropsy and ascites exist together, and sometimes a cysted tumour simulates ovarian dropsy, and Mr. B gives examples of these anomalies. Dr. G. GOD ROGERS relates some particulars of a "Case of Emp and Pneumothorax," relieved by what is termed centesis of necessity, namely, the formation of a taneous opening in one of the intercostal spaces fo discharge of the matter. The case resulted from an i

to the side, which seemed to have caused pneumothorax and suppuration of the lung. Dr. H. BEIGEL contributes a paper on "Spirometry," by which is meant the measurement of the amount of air taken into the chest in respiration. Dr. GEORGE ROBINSON continues his paper on the "Home Treatment of the Earlier Stages of Insanity," and he chiefly insists upon two points, first, that the Medical practitioner should only *recommend* the imposition of restraint in any case; and secondly, that the arrangements of an ordinary house should be assimilated as much as possible to those of a modern asylum. Mr. CHRISTOPHER HEATH proposes a "Method of Extracting a Hair-pin from the Male Urethra." The proposition is founded upon a case recorded by Mr. H. Thompson, in which that surgeon removed a hair-pin from the urethra. Mr. Heath has made experiments upon the dead body from which he is led to believe that, if such a case should again occur, the best treatment would consist in grasping the urethra so as to approximate the ends of the pin and then passing over them a tube, and so extracting the whole from the urethra. Mr. E. S. P. BEDFORD commences some papers on the "Diseases of Tasmania," but his present communication records three cases of operative surgery.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. A. B. GARROD contributes the first of the lectures now in course of delivery by him at the College of Physicians on the "British Pharmacopœia: its Construction, its Comparison with the London Pharmacopœia, and the Value of its New Remedies in the Treatment of Disease." In the remarks we have ourselves made upon the Pharmacopœia, we have anticipated many of the remarks made by Dr. Garrod in this lecture, which, therefore, does not require a detailed analysis at our hands. In speaking of the *acidum sulphurosum* of the New Pharmacopœia, it was mentioned that this substance was chiefly employed as an external application, more particularly for the destruction of some of those cryptogamic forms of vegetation which are now considered to constitute the essence of certain skin-diseases. Dr. GEORGE HARLEY continues his lectures on "The Urine and the Diseases of the Urinary Organs," and he now describes the varieties observed in the quantity of urine in connexion with the amount of drink and of food ingested, and with the cutaneous and pulmonary exhalation. The influence of the stools, of sex and age, and of diseases and remedies, is also described. Mr. WOOD continues his communications on "Rupture," and in the present paper he describes the anatomical characters of the inguinal hernia, which he illustrates by woodcuts. Dr. LEARED relates a "Case of Cerebral Disease, apparently Tubercular Meningitis, terminating in Recovery." The treatment adopted was the application of cold lotions to the shaven scalp, followed by the local use of iodine and the internal administration of iodide of potassium in five grain doses, together with strong beef-tea and wine when the strength seemed to be failing.

THE 'BRITISH MEDICAL JOURNAL.'

Mr. HENRY LEE commences a series of clinical lectures on the "Obliteration of Varicose Veins," his present lecture being founded upon a case of varicocele, in which two needles were placed between the enlarged veins and the vas deferens, and slight pressure was applied to the veins by means of ligatures passed over the ends of the needles. The veins, thus compressed by the ligatures, were then divided midway between the two needles by subcutaneous section. In a few days the needles were removed, and in the course of some months the cure became complete. Mr. LEE then reviews the different modes adopted by surgeons for the obliteration of varicose veins, and he shows that the danger of wounding veins does not arise from the production of lymph on the lining membrane of the veins; but from the deposition of fibrine from the blood. When the coagula are formed from healthy blood, they are easily removed from the spot where they are deposited, and appear to produce very little inconvenience to the system; but if the coagula have begun to undergo morbid changes, or if they have already become mixed with other secretions in their neighbourhood, the most severe symptoms of blood-poisoning may be produced.

THE 'MEDICAL MIRROR' A MONTHLY MAGAZINE OF CURRENT MEDICAL LITERATURE AND NEWS. Vol. I. January, 1864.

Under the above title a new Medical Journal has made its appearance at the commencement of the present year. The editorial programme deprecates the opinion that some people may entertain of there being enough medical periodicals already, and it announces that the object of the new journal is to present essentially the features of a review, combining, however, information on current topics of professional interest. The original communications of the present number consist of an able paper, illustrated by cases, on "Astigmatism," by Mr. J. ZACHARIAH LAURENCE; "Some Remarks on Cases of Imperfect Development of the Uterus," by Dr. A. MEADOWS; "Surgical Cases at the London Hospital," reported by Mr. C. F. MAUNDER, the Senior Assistant-Surgeon; and a paper on "the Advantages Derivable to the Medical Profession and the Public from the Establishment of Village Hospitals," by Mr. ALBERT NAPPER, of Cranley. The rest of the number consists of Reviews of Books and Pamphlets, a Retrospect of British and Foreign Medical Journals, and a general glance at the Medical Intelligence of the Month. The Journal is very well got up, as to paper and printing, and the tone of the contents exhibits a desire on the part of the promoters of this new serial to uphold the dignity of the Profession, and to open a new source of medical information and criticism in addition to those which we already possess.

THE 'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

Amphoric Voice and Breathing in Pleurisy.—Epileptiform Neuralgia.—Exophthalmic Goitre.

On resuming his chair after the long vacation, Mr. Trousseau, dispensing with any introductory address to the audience in his crowded lecture-room, ever eager to profit by the eloquent tuition of the eminent Professor, at once entered on the description of certain facts which seem to detract from the rigid interpretation of a class of stetho-

scopic signs, which, since the days of Laennec, have always been more or less closely associated with the existence of extensive pulmonary ulceration. We allude to amphoric voice and breathing.

Practitioners were already aware that these phenomena are not only observable in considerable pulmonary excavations, but may also arise from the presence of a fibro-plastic or other tumour adjacent to the surface of a healthy lung (Woillez, *Archives de Medecine*, 1852), or from the pressure exercised on the lung by a pleuritic effusion ; thus, in 1853, Messrs. Rilliet and Barthez published a paper founded on six cases in which this anatomical change was the obvious cause of amphoric voice and breath-sounds, no pulmonary excavation existing at the time. This memoir derived additional interest from the fact that in several of the instances adduced a gurgling sound analogous to that which is characteristic of ulceration was plainly detected. In the ensuing year, 1854, Mr. Béhier published two fresh cases of amphoric respiration in puriform pleurisy. In addition, M. Landouzy stated in 1856 that he had not only heard the amphoric sounds in aggravated cases in which he was compelled to have recourse to thoracentesis, but also in instances of simple uncomplicated pleurisy, and this assertion Mr. Trousseau now confirmed from the result of his own experience.

The first case which attracted Mr. Trousseau's notice occurred in 1853, when a young woman aged twenty presented, in the course of a severe attack of typhoid fever, very serious chest symptoms indicative of bronchitis, broncho-pneumonia and pleurisy. On the eighth day after the complications set in, amphoric breathing and voice-sounds were discerned, together with cavernous rhonchi during the paroxysms of cough. Acute phthisis was surmised to exist, but a complete cure was nevertheless effected in a few weeks, and it is needless to add that this could not have occurred if the diagnosis had been correct.

In a second patient, at present occupying a bed in the wards, effusion took place on both sides of the thorax after a few days fever; at first a muffled souffle with ægophony was heard on auscultation, but in a short time these signs were replaced by genuine amphoric souffle, attended with bronchophony and gurgling sounds very similar to those produced in a cavity. Yet it is impossible to admit that tuberculosis could have progressed so rapidly, and this surmise is further contradicted by the gradual improvement of the condition of the woman who previously enjoyed perfect and uninterrupted health.

In a third case, Mr. Trousseau expressed doubt on account of the presence of persistent nummular expectoration.

The two last cases adduced by the Professor refer to women who died after presenting the amphoric signs. In one, a copious eruption of tubercles was discovered after death ; in the other, no anatomical signs of tuberculosis were detected ; both had suffered from pleurisy. The contrast offered by these cases suggests to the pathologist the necessity of considerable reserve ; although the amphoric sounds may be connected with a peculiar liability to vibration of the walls of the chest, and be referrible to pleurisy with or without effusion, or to the pressure exercised by a tumour on the surface of the healthy lung, they may also be induced by tuberculosis, and the practitioner should therefore be guarded in his prognosis. Here, however, it is, as usual, a safe rule not to rely on a solitary sign, and always to view exceptional cases with a considerable degree of suspicion.

In his remarks on the pathology of neuralgia, Mr. Trousseau dwelt on a condition which he acknowledges to have for many years, like others, confounded with facial neuralgia, or neuralgia of the fifth pair, but which, by its analogy with painful *aura epileptica* now appears to him to merit a distinct place amongst the varieties of neurosis, under the denomination of *epileptiform neuralgia*.

This distressing and spasmodic affection well deserves the denomination of *tic douloureux*, and differs from genuine neuralgia of the face by the suddenness of its appearance, the excruciating intensity of the pain, the entire cessation of all suffering after a duration pretty constantly the same, and the impossibility of relieving the paroxysms which recur at variable intervals, of one or ten minutes, one or two hours, etc. Some two years since, a patient in Mr. Trousseau's wards, experienced thirty attacks in the hour ; he could neither eat, drink, nor sleep, and this torture persisted sometimes for two successive months without interruption. The Professor was once consulted at his house by a prefect who had scarcely taken a seat when he sprang up, and applying his hand to the right side of his face, which was in a state of spasmodic convulsion, walked up and down the room stamping and swearing like a mad man. This strange scene lasted about a minute, when the pain subsided, and the patient apologised for his violence and agitation. Mr. Trousseau assured him he fully understood the nature of his sufferings, which he might mitigate but could not promise to remove altogether. This peculiar form of neuralgia, which affects the trifacial nerve only never yields in a complete and permanent manner.

Thus without proscribing the section of the nerve which Mr. Trousseau might even now resort to in a case of this kind, he greatly doubts whether the procedure can be expected to produce lasting results. Blisters dressed with morphia, hypodermic injections, etc., are utterly unavailing. One remedy, and one only, proves an efficient palliative viz., large doses of opium.

Mr. Trousseau brought forward in support of this statement, the case of an aged lady from the city of Antwerp who was a kind of martyr to this kind of neuralgia, which was allayed with enormous doses of opium. The duration of each paroxysm varied from a few seconds to three minutes, and the pain attacked in turns the three main branches of the nerve, rapidly extending to every filament and inducing convulsive action of the muscles of the jaw. Twenty of these fits occurred within an hour. An interval of a fortnight or a month sometimes elapsed without recurrence of the disorder, but it invariably returned with the same violence. In this instance Mr. Trousseau prescribed each day at first three or four grains of muriate of morphia which he gradually increased to one drachm. Great improvement was effected, but the treatment being expensive the professor obtained for the patient the drug at cost price when she took as much as two drachms a day with much relief, and singular to say, without any disturbance of the digestive functions. The tolerance consequent on habit is sometimes incredible : Mr. Trousseau stated that in one instance he had seen a brush-maker drink several full glasses of laudanum. It is however prudent to exhibit the medicine in very gradually increasing doses, and to watch carefully its effects on the system.

We shall conclude with a few remarks on exophthalmic goître, a disease on which Mr. Trousseau has bestowed much attention, and which has been noticed on several occasions in the present journal.

Further inquiry into the pathology of the affection has led to practical and theorettcal results which we are bound to notice. Thus the morbid condition in question is viewed by Mr. Trousseau, if not as a neurosis attended with local congestions, at least as a disease which originates in some modification of the vaso-motor system.

In support of this position, we may adduce the particulars of the interesting *post-mortem* examination of a woman afflicted with exophthalmic goître, who died in a few hours from the effects of apoplexy. The sympathetic nerve and its ganglia were carefully inspected, and the superior cervical of that system was found in a marked state of congestion and the texture of the ganglia had undergone alteration, a portion of their substance being replaced by cellular tissue. The experiments of Claude Bernard, Schiff and others prove that disease of the sympathetic or vaso-motor system induces peculiar changes in the organs placed under the influence of the affected parts of the nerve ; that these changes consist, in the first instance, consequently on a paralysis of the vascular parietes, in congestion, and hypertrophy, followed by impaired nutrition, atrophy, and a state analagous to cirrhosis. The texture of the organ ap

to be destroyed by the accumulation of cellular or conjunctive tissue. This was precisely what was observed in the patient who suggested the present remarks. In evidence of the first stage above described naught was discovered but hypertrophy of the layers of fat, about the heart and within the orbit. The thyroid gland, liver, spleen, kidney, and even the uterus were in a state of unmistakeable atrophy.

At the onset of the disease, which is more commonly observed in the female sex, nervous disturbances are always met with, so intense as to induce mania when the mind is affected; in other cases originating in the gastric viscera, and giving rise to bulimia with rapid concomitant loss of flesh, or invincible distaste for food; exophthalmos and bronchocele may both appear in the course of twenty-four or thirty-six hours, and subsequently subside, being especially noticeable under the influence of the excitement of the circulation which causes in these organs a sort of erectile congestion. All these circumstances indicate very distinctly the nervous nature of the disease.

The surmise receives further confirmation from the good effects of a methodical resort to hydropathic measures. Hitherto the only treatment prescribed consisted in the use of chalybeates and digitalis, and iodine both internally and externally; the digitalis being intended to calm the palpitations, and the iodine to subdue the bronchocele. Applications of ice to the throat and to the region of the heart have also been recommended, but these various medications only produce transient amelioration, whereas with the assistance of hydropathy an absolute cure has been effected. This system must therefore be viewed as of paramount importance in the management of exophthalmic goitre. We should not omit to state that on a recent occasion, Mr. Trousseau prescribed by mistake tincture of iodine for tincture of digitalis, and some six weeks after, the patient brought back her prescription, stating herself to be much relieved. The Professor, who previously entertained but a poor opinion of the efficacy of tincture of iodine in such cases, has again tested the value of the drug, and its external use, combined with hydropathy will perhaps, in future prove the most useful resource of the therapeutist in this singular disease.

GENERAL CORRESPONDENCE.

SYMM AGAINST FRASER AND ANDREWS.

To the Editor of the Medical Circular.

SIR,—Permit me to say in your inestimable Journal, that in ninety-nine cases out of every hundred, the sole causes of law suits being instituted with such avidity against Medical practitioners, is owing to a snake in the grass, and that snake is too often a rival practitioner—*i.e.*, if he should be called in to see the patient after a rival is dismissed by the family from attending the case. If a doctor is called in to a case, say, for instance, a burn or a scald, and he prescribes carron oil at the onset; the next that goes in to attend will say the application should have been lime-water from the first; need I say that whatever the heart is most prone to our evil nature will help forward, and thus the meddling doctor will maintain his position at all hazards of injuring a rival, and this, too, for mere earthly consideration, and yet pretend to follow the meek and lowly, by doing as you would be done by. Moreover, it is notorious that Medical practitioners disagree upon many matters connected with the practice of physic; and I may venture to add, that few men are more narrow-minded and jealous than its members are one to another.

I am, &c., HERTS.

THE CLERGY AND THE HERTFORD INFIRMARY.—At the annual meeting of the Governors of the Hertford Infirmary, it was stated that in addition to the regular funds of the institution, about 120*l.* is required annually. Of this sum during the past year 119*l.* has been received from the clergy.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY.

(Continued from page 85.)

Dr. WILKS presented the following specimens :—

I. FIBROUS TUMOUR ATTACHED TO THE KIDNEY.

This specimen he brought to the Society as an example of a fact which he thought was scarcely sufficiently recognised —that the internal organs of the body are liable to the same class of affections as those which are described as new growths or tumours on the exterior of the body. He said that surgeons had discriminated between various forms of external tumours as regarded their structure and malignancy, and he thought that the same could be done with respect to the affections of the internal organs. For instance, many of the diseases of the stomach formerly called cancerous, or funcoid, consisted of various kinds of growths, described by the surgeon as fibrous, recurrent fibroid, &c. Again, the so-called intra-thoracic cancers often consisted of growth which on the external part of the body would be styled the firmer and softer varieties of recurrent fibroid; and the same might be said of the kidneys, ovaries, and other structures of the body.

II. PLASTIC LYMPH LINING THE LATERAL VENTRICLE OF THE BRAIN.

A man aged forty was admitted into Guy's Hospital, under Mr. Birkett's care, for fracture of the skull and injury to the brain, which he survived a fortnight. The orbital plate was comminuted and the dura mater torn. At the anterior lobe of the brain there was an abscess, and this was closely contiguous to the anterior cornu of the ventricle. On opening the latter, it was found to be lined by a tough layer of lymph, which formed a complete cast of the cavity. The roof, floor, and descending cornu were covered, and thus a hollow sac or cast of the ventricle was constituted. It resembled a croupous membrane as seen on an inflamed trachea, and could be removed whole. It contained some purulent matter. Dr. Wilks said he had never met with a similar case before in which the ventricle had poured out a plastic lymph of this kind.

Dr. HARLEY related a case of Abscess in the Brain having a bearing on the case of Dr. Wilks, and described a false membrane lining one of the ventricles.

ADENOCELE OF THE BREAST.

Mr. BIRKETT showed this from a woman aged thirty years. It was a large and fresh specimen.

A TUMOUR FROM THE EYEBALL OF AN OX.

Mr. PARTRIDGE showed this as a rather rare specimen. A large bunch of hairs grew from the surface of the tumour, which sprang from the outer portion of the cornea and adjacent sclerotic. Such a thing was very rarely found in the human subject. He referred to cases by Mr. Wardrop, Von Ammon, Mr. Bowman, and Mr. Hulke.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH, WESTMINSTER, JAN. 25.
(Sittings in Banco, before the LORD CHIEF JUSTICE, Mr Justice CROMPTON, Mr. Justice BLACKBURN, and Mr. Justice MELLOR.)

EX PARTE SERGEANT V. THE GENERAL COUNCIL OF MEDICAL REGISTRATION.

This case raised an important question, under the Medical Act, 1858, affecting the Medical Profession. Under this Act a registry is to be kept of Medical Practitioners: and it is declared to be the duty of the registrars to keep it correct, and to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses or qualifications of the persons registered, every person legally qualified according to the Act at the time of the passing being entitled to claim registration; and to enable the respective registrars duly to fulfil the duties imposed upon them, the registrar is to write a letter to any registered person, addressed to him according

to his address on the registrar, to inquire whether he has ceased to practice or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter, his name may be erased; provided also that the same may be restored on the direction of the General Council, should they think fit to make an order to that effect. And by another section the Council have power to strike off the names of Practitioners whom they shall, after due inquiry, judge to have been guilty of infamous conduct in any Professional respect. And only those who are registered are to be deemed duly and legally qualified Practitioners. In this case the applicant was qualified and registered at the time of the passing of the Act; but the usual annual letter having been since sent to him addressed to his last place of residence, it had received no answer within the six months (owing to a change of address), and the Council proceeded to strike out his name. In Trinity Term last he applied for a *mandamus* to the Council to restore his name under their general power to do so, "if they should think fit;" but the Court doubted if this raised a legal duty to do so, so as to render them liable to a *mandamus*. They, however, granted a rule *nisi* under another section of the statute, to hear and determine on his application to be registered *de novo* on due proof of his possession of the requisite legal qualification.

Mr. M. Smith, Q.C. (with him Mr. Horace Lloyd), appeared on the part of the Council to show cause, urging that, if the application were acceeded to, the result would be that Practitioners who had been struck off for misconduct would be able to insist on reinstatement.

The Court, however, pointed out that by the Act the registrar is only to insert the names of Practitioners if satisfied by proper evidence that he is entitled to registration, which he would scarcely be in the case supposed; and,

The Lord Chief Justice put the case of a Practitioner whose name was struck off through mere *laches* or neglect on his part in not answering the usual letter. Surely, he was not to be excluded for ever from the practice of his Profession?

Mr. M. Smith said the Legislature had entrusted these eminent persons who constituted the Council with such powers, and it was not to be presumed that they would improperly exercise them.

Mr. Henry James appeared in support of the rule; and after some discussion,

The Court said the question was one of far too much doubt and too great importance to be decided summarily either way, and the *mandamus*, therefore, had better issue, with a view to raise the question regularly upon the record, so as to admit of its due argument and deliberate determination. The Court, without calling on Mr. James to support the rule *nisi*, made it absolute for a *mandamus*.

OBITUARY.

DR. MICHAEL LAMBTON ESTE.

We have to record the death of the above-named estimable gentleman at the advanced age of eighty-six. At an early period of life he entered the medical service of the army, having been an assistant-surgeon in the 3rd Foot Guards in 1800, and surgeon in the 1st Life Guards in 1812. He was the senior medical officer in the Royal Household Cavalry through the last Continental War, and in the course of his career he served both in Egypt and in the Peninsula, receiving numerous decorations, both English and foreign, for his services. During one part of his military life, he had the good fortune to form the acquaintance of the illustrious Lord Nelson, and filled for a time the office of his private secretary. Dr. Este was an exceedingly well-informed man, and possessed much literary taste, having written books on the "Baths of the Romans," on the "Ruins of Rome," and many other subjects. Notwithstanding his advanced age, he was a very agreeable companion, and until a very recent period he was fond of joining his old friends at convivial meetings which he enlivened by his power of conversation, and his anecdotes of the scenes and the persons he had met with in his career.

MR. WILLIAM JOHN WICKHAM, OF WINCHESTER.

We regret to record the death of Mr. Wickham, of Winchester, one of the consulting surgeons to the Hampshire County Hospital. Mr. Wickham and his ancestors have occupied a high position in surgery at Winchester, for above a century; and have left a name and reputation, as honourable and lasting as the venerable city itself. Mr. Wickham was educated at the Borough Schools, and subsequently studied at Edinburgh and Paris. He passed the College of Surgeons in 1815, and became honorary Fellow in 1843. Mr. Wickham had been out of health for some months; but latterly, repeated attacks of epilepsy terminated his useful life. He had been for more than forty years connected with the Hampshire County Hospital, and during that lengthened period conducted a very extensive private practice. His contributions to medical literature were a 'Treatise on Diseases of the Joints,' with various papers on surgical subjects in the journals of the day. As an operator and lithotomist, he was very successful, and his operations were extended to various parts of the county, and elsewhere. — 'British Medical Journal.'

DR. OSBORNE.

We regret to record the death of another eminent member of the medical profession, Dr. Jonathan Osborne, who expired on Saturday, at Blackrock. Dr. Osborne was Professor of Materia Medica in Trinity College, and was also for a great number of years attending physician of Mercer's Hospital and of Sir Patrick Dun's Hospital. The deceased gentleman was highly esteemed by all who had the privilege of knowing him. Dr. Osborne took the degree of M.B. in 1818, and that of Doctor of Medicine in 1837. In October 1840, he was elected King's Professor of Pharmacy and Materia Medica, on the foundation of Sir Patrick Dun's Hospital, in the room of Dr. Crampton. He held that office until his death, having been re-elected at the expiration of each period of seven years of the professorship. He continued to lecture up to the recess of last Christmas. He was also Physician to Mercer's Hospital. He was an excellent classical scholar, and a contributor to various medical periodicals. He was also remarkable for the possession of a store of quaint literature. He was the inventor of an animal heat thermometer, an instrument which is likely to turn out very useful.

FUNERAL OF THE LATE SURGEON SMYLY.

The funeral of this esteemed and lamented gentleman took place on Saturday, the 23rd ult, and was attended by many of the members of his own profession, and a large number of those who knew and respected the unobtrusive worth and practical piety by which he enhanced the value of his high talents and laborious career. The life of Surgeon Smyly was more useful than eventful, and, though other contemporary with him in the Medical Profession have gained greater distinction, few have done more solid service, and none have acquired more general and permanent respect. The energy with which he devoted himself to all charitable objects and the earnestness of his religious views were scarcely concealed by the humility of his deportment. The affectionate regard which he inspired amongst young men is proved by the numerous attendance not merely of the medical students who received his instruction at the Meath Hospital, but of those belonging to other schools, and the presence of more than a hundred children who are being educated in the ragged schools which his benevolence so largely aided, was an affecting tribute to his worth.

The chief mourners were—Mr. Philip Crampton Smyly and the two younger sons of the deceased; Mr. Smyly, his brother; and Mr. Thomas Franks.

The funeral procession left the residence of the deceased in Merrion-square at nine o'clock, and arrived at Mount Jerome Cemetery at half-past nine. The coffin having been taken out of the hearse, was borne upon the shoulders of students of the Meath Hospital to the Cemetry Chapel, where the Rev. C. F. MacCarthy read the Burial Service.

The Rev. Maurice F. Day then delivered an address, in which he described the life of Surgeon Smyly as a life of active and unobtrusive piety. He had been intimately acquainted with him for many years, and had opportunities of observing his bland and courteous manner, his conscientiousness, and his earnestness in every good undertaking. There was no religious institution or charitable object in which his sympathies were not enlisted, and to which he was not ready to give his cordial and effective aid. The life of Surgeon Smyly had been singularly consistent with his professions, and his high ability and great professional skill were always freely given in assisting the suffering poor. Many acts of Christian kindness performed by him in secret had come to light, and showed the generosity of his disposition, and the practical character of his religion. In every thing that he did he had endeavoured to act from a true motive, and towards a worthy end. He was as remarkable for humility as for the honesty of his professions; and, though he never shrank from the performance of duty, he took care never to give offence to any one. The reverend speaker touched with much earnestness and feeling upon these and other traits in the character of his deceased friend, and towards the conclusion of his address referred more particularly to the efforts of Surgeon Smyly in connection with charitable institutions. The interest which he took in the foundation of ragged schools, in which children might be instructed in the fear of God and the knowledge of His Word, was equalled by the activity of his exertions in supporting them. In this field of labour his name would be long remembered with gratitude, and his example would be productive of great good, if followed by those who had similar opportunities and means of usefulness. Many of his professional brethren knew how benevolently he employed his talents. His gratuitous visits to the suffering poor were made with as much regularity as his paid visits to wealthy patients. He never looked for any reward save the approval of his own conscience, and many whom he had visited as sick and afflicted had afterwards found him a generous friend, as well as a skilful surgeon. He honoured the Sabbath-day by receiving no fees for medical attendance upon it, and a tenth of his income was regularly given to religious objects, and how much more went to charitable purposes could not easily be computed. The death which had interrupted this career of usefulness would be a heavy blow, not merely to his own circle of friends, by whom he would never be forgotten, but to the institution which he supported with so much liberality and zeal. The Rev. Mr. Day having spoken of the unexpectedness of the death of Surgeon Smyly, urged upon those who heard him the duty of following such an example, and dwelt upon the happy end of the consistent and honourable life which he had tried to describe.

The remains were then removed from the chapel and deposited in the family vault.

Births, Marriages, and Deaths.

BIRTHS.

BLACKWOOD.—On the 20th ult., at Kirkintilloch, Dumbartonshire, the wife of Dr. Thomas Blackwood, of a son.

BRUCE.—On the 22nd ult., at Camden crescent, Bath, the wife of J. R. Bruce, M.D., late of the Royal Scots Greys, of a son.

HASLAM.—On the 16th ult., the wife of G. H. Haslam, Surgeon, of Shropshire street, Market-Drayton, of a daughter.

HORSFALL.—On the 18th ult., of Sowerby bridge, near Halifax, the wife of Dr. James S. Horsfall, of a daughter.

HOTT.—On the 20th ult., at Bromley, Kent, the wife of E. Hott, L.R.C.P.L., of a daughter.

SIMPSON.—On the 13th ult., at Vittoriosa, Malta, the wife of T. R. Piekthorn, Surgeon of H.M.'s Ship "Hibernia," of a son.

SANDERS.—On the 22nd ult., at Stafford street, Edinburgh, the wife of Wm. R. Sanders, M.D., of twin daughters.

SKEGG.—On the 23rd ult., the wife of John J. Skegg, M.R.C.S.E., of St. Martin's place, of a daughter.

STEVENS.—On the 20th ult., at Hoddesdon, Herts, the wife of R. J. Stevens, M.R.C.S.E., of a daughter.

MARRIAGES.

DOWN—PARKER.—On the 27th ult., at Trinity Church, Bridgwater, Somerset, Henry W. Down, M.R.C.S., of Glastonbury, Somerset, to Lucy Anne, second daughter of the late James Parker, Esq., M.R.C.S.

SEWARD—PENFOLD.—On the 21st ult., at Selsey, Charles Seward, Esq., Surgeon, of Littlehampton, Sussex, late 4th Battalion Prince Albert's Own Rifle Brigade, to Margaret, eldest daughter of Hugh Penfold, Esq., of Selsey, near Chichester.—No Cards.

DEATHS.

ANNAN.—On the 22nd ult., at Kinross, R. Annan, L.R.C.S.Ed.

CRAIG.—On the 18th ult., at Seymour street, Holt hill, Birkenhead, W. Craig, Surgeon, R.N., for many years Surgeon and Agent of the Royal Navy for Liverpool, aged 72.

FAUSSETT.—On the 17th ult., at Balluia, Co. Mayo, R. Faussett, M.D., aged 86.

LYE.—On the 17th ult., at Hereford, J. B. Lye, M.D., aged 76.

OSBORNE.—On the 6th ult., at Nethergate, Dundee, Geo. Moore Osborne, M.D.

OSBORNE.—On the 22nd ult., J. Osborne, M.D., of Clermont, Blackrock, Co. Dublin, Professor of Materia Medica, Trinity College, Dublin.

PALK.—On the 1st ult., at Union Missouri, United States, of typhus fever, Wm. Palk, M.D., aged 63.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th ult.:—Thomas Graham Bennett, Brighton; Jean Baptiste Blanchet, M.D., Quebec; Charles Carr, Newcastle; Edward Colden, Wandsworth road; John Gordon Coulter, M.D., Belfast; Charles Thomas Dalley, Markfield, Leicestershire; George Eastes, Folkestone; John Edwin Eddison, Leeds; Richard Hughes, Llanddeniolen, Carmarthen; John Roaf Ireland, Kingswinford; Samuel Forest Leech, Mileend; Alexander James Low, Jersey; William Cubitt Lucey, Bermondsey; Charles Durrant Pearless, East Grinstead; John Jones Phillips, Towyn, North Wales; William Henry Power, Queen square, Bloomsbury; David Palmer Ross, M.D., Penang, East Indies; George Shannon, M.D., Magherafelt, Co. Derry; George Henry Watson, Jersey; John George Waters, Cheshunt; William Wigmore, Oswestry; Thomas Hewlett Worger, Chiswell street, Finsbury.

The following gentlemen were admitted Members on the 27th ult.:—William Battye, Plymouth; William Cheetham, Rochdale; George Henry Cresswell Cooper, Woburn place; Charles John Denny, Aston, Warwickshire; John Swinburn Anthony Dickinson, Norfolk street; William Daniell Dunn, Devonport; Richard Thomas Freeman, Hatcham; Robert George Gammage, Sunderland; Thomas Griffiths, Merthyr Tydvil; Eugene St. Paul Hadwen, Waterloo road; Albert Egerton Hale, Nantwich, Cheshire; George William Harrison, Whitchurch; Herman Boerhave Holman, Crediton, Devon; John Lloyd, Birmingham; Samuel Morris, Prescot, Lancashire; Frederick Powell, St. John's wood; James Joseph Rablah, Walsall, Staffordshire; Samuel Rooth, M.D., Chesterfield; William Wallace Somerville, Wakefield; James Shackleton, Whitworth, Lancashire; William Frederick Watts, Dewsbury.

At the same meeting of the Court, Mr. Henry Ashlin Close, of H.M.S. 'Royal Albert,' Plymouth, passed his examination for Naval Surgeon.

The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 19th ult.:—R. F. Allen, Middlesex Hospital; R. J. Andrews, Guy's; F. Argles, King's Col-

lege ; C. E. Blair, Guy's ; J. B. Blanchet, M.D., Montreal, St. Bartholomew's ; R. Brennan, St. George's ; E. Child, Charing cross ; A. E. Conolly, Dublin School ; J. G. Coulter, M.D., Belfast School ; E. P. Davies, Dublin School ; W. A. S. Dykes, Hull ; H. G. B. Harris, St. George's ; T. E. D. Hayes, Guy's ; W. T. G. Hicks, Guy's ; G. H. Hills, Guy's ; J. Hope, Newcastle ; E. Horne, Charing cross ; P. le F. Kilroy, Middlesex ; J. C. Leach, University College ; J. C. Macaulay, Birmingham ; H. C. Manley, Belfast School ; T. H. Morris, St. Thomas's ; W. Powles, London ; J. C. Roberts, Guy's ; G. Shannon, M.D., Belfast School ; W. B. Stirling, London ; D. M. Williams, Charing cross ; E. R. Woodford, University College ; J. H. Wraith, Charing cross.

The following gentlemen passed their primary examinations on the 20th ult :—B. Blewitt, London Hospital ; C. Broom, Guy's Hospital ; W. H. Bryant, St. Bartholomew's Hospital ; J. Carless, St. Thomas's Hospital ; F. Chabat, St. Thomas's Hospital ; T. Cuppage, Edinburgh ; F. Flint, King's College ; W. R. Goodfellow, London Hospital ; W. H. Harding, King's College ; T. Hora, St. Mary's Hospital ; H. Hyde, King's College ; H. M. D. Jones, Heidelberg ; A. Kisch, St. Thomas's Hospital ; C. G. Leacock, King's College ; R. N. Macpherson, Edinburgh ; W. M'Connell, Dublin ; W. May, St. Bartholomew's Hospital ; R. Z. Miller, Middlesex Hospital ; E. O'Leary, Dublin ; R. Orme, Guy's Hospital ; W. Pogson, Leeds ; J. F. H. Richardson, St. Bartholomew's Hospital ; J. Rogerson, London Hospital ; W. Skinner, Sheffield ; W. H. Strange, St. Thomas's Hospital ; J. Todd, London Hospital ; T. Warren, St. Bartholomew's Hospital ; W. L. White, Edinburgh.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 21st January, 1864 :—Warner Atkinson, Harrington square, N.W. ; Frederick M'Nair, Guy's Hospital.

THE ELECTION TO THE COURT OF EXAMINERS AT THE COLLEGE OF SURGEONS.—The friends of Mr. Gulliver complain that, before the late election, every means was adopted which could prejudice his chance of success. They state that an active canvass was set on foot by certain supporters in the Council of Professor Partridge, and that unfounded statements were inserted in some of the Medical journals to the effect that Mr. Gulliver, not being a Surgeon to any Hospital, would probably not present himself for election, and that the contest would be between Messrs. Partridge and Hilton. We need scarcely state that this assertion did not emanate from Professor Gulliver, and had no foundation in truth. Mr. Gulliver abstained from everything like a solicitation of votes ; he never opened any communication with any member of the Council on the subject, and was content that his claims should stand on their own merits. That our readers may judge what these claims were, we append a list of some of Mr. Gulliver's services and contributions to Surgical and pathological knowledge. We omit in the list his larger labours in the higher branches of animal and vegetable physiology, which are universally known, and to which our own pages have, in the last two years, borne ample evidence. Mr. Gulliver was a long time in charge of the General Military Hospital at Fort Pitt, performing all the surgical operations there. For upwards of twenty years since he was never without charge, in the regular course of duty, of other Military Hospitals. He made great part of the museum at Fort Pitt and of the catalogue thereof. He had there the superintendence of numerous junior Medical officers, with whom he always maintained the most friendly relations. When he left the army, and ever since up to this date, he was engaged in a small, but active professional practice, amongst his old military connection, never seeking to extend it, because he possesses independently ample means, and is attached rather to the scientific pursuits of his profession than to its more lucrative department. Amongst his published papers on Surgery and Surgical pathology are—"Experimental Inquiries concerning Necrosis," 'Med.-Chir. Trans.,' 1836 ; "Discovery of the Softening of Coagulated Fibrin as a Pathological Element Distinct from Pus," 'Med.-Chir. Trans.,' 1839 ; "Discovery of the Fatty Degeneration of Arteries, Testes, Lungs, etc., and that this Disease is the Proximate Cause of Aneurism, Sanguineous Apoplexy, and Decay of the Tissues," 'Med.-Chir Trans.,' 1843 ; "On the Reparation of Fractured Bones," 'Edin. Med. and Surg. Journal,' 1835 ; "On Shortening of the Neck of the Femur in Young as well as Old People," papers in different numbers of the 'Edin. Med. and Surg. Journ.,' 1836 ; "On Fracture of the Femur, with Inversion of the Limb," 'Ibid.,' 1836 ; "Experimental Inquiries concerning Fracture of the Patella, showing under what Conditions Union by Bone will or will not occur," 'Edin. Med. and Surg. Journ.,' 1837 ; "On Diseased Joints in the Army Medical Museum," 'Edin. Med. and Surg. Journ.,' 1837 ; "Experimental Inquiry concerning Buffy Blood," 'Ibid.,' 1845.—'Medical Times and Gazette.'

CORYZA OF INFANTS ; DR. HAUNER'S PRACTICE. — In nurslings, catarrh of the nose may lead to serious consequences, extend to the throat and larynx, or interfere with the performance of suction. Dr. Hauner states that children have died from this cause. It is therefore important to treat the coryza, and the Munich Professor recommends the following measures for the purpose.—After carefully cleansing the nasal cavities with luke-warm water, the surgeon should touch the membrane with a brush dipped in a solution of nitrate of silver (from one to three grains to the ounce), or of fifteen grains of the sulphate of zinc or copper in one ounce of water.—The nose is then covered with compresses soaked in warm oil ; saline baths should be prescribed, and small doses of calomel, senna, or rhubarb.—'Journal of Practical Medicine and Surgery.'

BEQUEST TO ST. GEORGE'S HOSPITAL.—In the Court of Chancery, on Friday, was heard Goodwin v. Braine. The question was as to a gift to said hospital under the will of Mr. A. Morley, late of Cork street, Burlington gardens, hotelkeeper, dated May 1, 1850. The testator, besides other charitable gifts, declared that his trustees, and the treasurer president, governors, &c., of said hospital should hold 50,000*l.* on trust, to purchase for said corporation a parcel of ground within seven miles of the hospital, and erect thereon a house of reception, with suitable gardens and grounds, for poor convalescent patients, to be called "Atkinson Morley's Convalescent Hospital, for the benefit of poor patients from St. George's Hospital ;" but if such trusts could not be legally carried out, the money was to be applied to such purposes of the institution as said corporation could legally appropriate. The testator died in June 1858, and his will was proved in August, 1858. The testator left a legacy to one of his nephews, on condition that he should execute a release to the trustees. The nephew having refused to do so, a question arose as to whether he had not forfeited the legacy. The nephew now attended, and consented to execute the release.—Vice-Chancellor Stuart ordered that he should have his legacy. He also directed a purchase by the trustees, and ordered a reference to chambers to settle a proper scheme ; the treasurer to lay proposals for the purchase of land, and the trustees and the corporation and treasurer to be at liberty to apply for such direction as may be necessary for carrying into effect the trusts and purposes of the will as to a convalescent hospital.

MORTALITY OF LIVERPOOL.—The annual report of the medical officers of this borough states that during the past year the deaths registered in the borough amounted to 15,266—a number greater than in any year since 1858, and 524 above the corrected average of the last decennium.

DEATH FROM THE IMPROPER USE OF MERCURIAL OINTMENT.—On Monday last, an inquest was held at Kilkenny before John Jellet, Esq., on view of the body of a girl aged thirteen years, named Martha Hoy. Some cutaneous affections having appeared on the deceased's head, her mother procured a quantity of strong mercurial ointment, which was injudiciously applied to the parts affected. Violent salivation and inflammation of the mouth ensued. Her throat became swollen to such a degree that no food could pass it, and she consequently died of starvation. Dr. Hackett gave evidence as to the cause of her death, and the jury returned a verdict in accordance with the facts.—'Kilkenomena Observer.'

ROBBING AN INFIRMARY.—One of the female patients of the Aldershott Infirmary, who had secretly left that institution without giving notice, taking with her the Infirmary clothing, she then wore, has been found guilty of the robbery at the Odiham Petty Sessions, and imprisoned for the offence.

VARICOSE VEINS; DIACHYLON AND LYCOPODIUM POWDER.—The 'Journal de Chimie Médicale' informs us that Professor Piorry, having derived benefit from the application of diachylon and lycopodium in various cases of inflammation and excoriation of the skin, has resorted to this remedy as a palliative in varicose enlargement of the veins. He spreads over the affected leg a thick layer of diachylon plaster, dusted with lycopodium powder, and in mild cases he has found that, although the patients do not refrain from exercise, all pain is relieved, and ulceration prevented.—'Journal of Practical Medicine and Surgery.'

A POOR-LAW SURGEONS' WIDOWS' FUND.—Dr. Phelan has ably advocated in a Dublin contemporary the necessity of providing some fund for the widows and children of medical practitioners when left, as is too frequently the case, unprovided for. He states that there are in Ireland 781 dispensary medical officers whose average salary is only 86*l.* per annum. Many of them being under 70*l.* He advocates the sanction of Parliament, which in the coming session will have to pass an act to continue the power of the Poor-Law Commissioners, to a scheme for appropriating 5 per cent. of their salaries to the formation of such fund. This he calculates will produce about 4,000*l.* per annum, not to mention additions which he thinks might reasonably be expected. He anticipates that this appropriation will meet with the hearty concurrence of the profession, an expectation which is strongly confirmed by the experience of the Indian Medical Service, in which a similar provision was formerly made on an extensive scale, but, on the abolition of the East India Company's rule, was discontinued, though much against the wishes of the *employés* of the government there. The inadequacy of the means of the Royal Medical Benevolent Fund to meet even a moiety of the cases requiring its aid is severely felt.

LACERATED WOUNDS INFLICTED BY LIONS.—On Thursday forenoon, about half-past ten o'clock, loud screams were heard at the Agricultural hall, Islington, proceeding from the direction in which the lions are kept in their caravan during the intervals of the performances. An impression at first prevailed that some of the animals had escaped, and were making an attack upon those who happened to be in their way. The truth, however, was at once made manifest, by seeing the body of an unfortunate man, named Thomas Greaves, who has within the last two or three days commenced his duties as keeper and feeder of the animals, drawn up close to the cage, and hearing from him the piteous cries and screams referred to. Some of the men immediately seized the long iron rods with a species of hoe at the end, by which the cage is cleansed, and rushed to the spot. It was then discovered that one of the larger lions had the unfortunate man Greaves's right hand in his mouth, while another had seized him by the thick part of the fore-arm, and had dragged the limb through the bars of the cage nearly up to the armpit. Having hot irons, the men at once set to work belabouring the lions over the heads and eyes, in order to make them loose their hold. This at the outset only tended to increase the ferocity of the animals, which, with loud yells, commenced tearing the flesh from their poor victim's arm and hand with their claws. It was not until the brutes were nearly blinded with the blows inflicted upon their eyes that they were induced to relinquish their gripe, when poor Greaves was drawn away with his mangled limb through the bars, and fell fainting into the arms of those who had rescued him from his horrible position. He was at once conveyed to the secretary's offices in Barford street, insensible and deluged with blood. It was then discovered that the hand was bitten completely through, and the flesh was torn off the arm in most parts to the bare bone, very nearly from the shoulder to the wrist. The poor fellow was placed in a cab, and accompanied to St. Bartholomew's Hospital, where, on examination by the surgeons of that institution, and after a conference, it was understood that, in consequence of the frightfully mutilated state of the arm and hand, amputation would be absolutely necessary, and it was to take place as soon as the sufferer should have sufficiently rallied from the first shock to the system.

SMALL-POX IN WASHINGTON.—Small-pox is becoming so prevalent in Washington that the House of Representatives have adopted a resolution recommending the municipal authorities of that city and Georgetown to take measures to ensure the vaccination of the citizens to prevent the further spread of the disease.

INSANE PAUPERS.—From a return just published, it appears that on the 1st of January, 1863, there were in England and Wales, 1,142,624 persons receiving relief, of whom 36,158 were insane; 23,032 being lunatics, and 13,126 idiots. Thus 3·17 per cent of pauperism is ascribable to insanity. Of these 15,790 were males, and 20,368 females.

THE SWINEY BEQUEST.—A meeting of the judges appointed under the will of the late Dr. Swiney to award, in concert with the Royal College of Physicians, on every fifth anniversary of Dr. Swiney's death, "a silver goblet of the value of 100*l.*, with gold coin to the same amount, took place on the 20th inst., at the house of the Society of Arts. The award was adjudged to Henry Summer Maine, Esq., D.C.L., for his work "On Ancient Law." The cup was executed by Messrs. Garrard and Co., from a design by Maclise, R.A.

A TESTIMONY TO OUR CLIMATE.—The 'Times' of the 20th ult. chronicles the death of eight persons between 70 and 80, of five between 80 and 90, and of four over 90; the united ages of these 17 persons giving an average of 82 years for each. On the 21st we read of 15 dying between 70 and 80, of eight between 80 and 90, and one over 90; the average of these 24 being very nearly 76 years a piece. On the 22nd there appeared two over 90, six between 80 and 90, and ten between 70 and 80; the average here being nearly 79. On the 23rd, 13 between 70 and 80, seven between 80 and 90, and one over 90, making an average of 79½ each. We suppose our American cousins would say, if these 80 individuals, whose longevity we have noticed, had lived anywhere else but in our own land of fogs and changeable weather, they would never have died at all.—'Notes and Queries.'

A DOCTOR OF MEDICINE AND HIS SUCCESSOR.—The Lord Chancellor of Ireland has appointed Mr. James Prendergast, his lordship's butler, to the post of train-bearer, vacant by the death of Thomas Sinton, M.D.

THE LATE PROFESSOR OSBORNE.—The following members of the medical profession attended the funeral of this lamented gentleman on the 26th ult:—Professors Law, Smith, and Stokes; Drs. Wilme, Duncan, Kennedy, Croker, Bevan, and Corrigan.

ALLEGED ATTEMPT OF A SURGEON TO POISON HIS BROTHER.—Mr. Richard Oke Millet, of Penpol, Cornwall, was charged on Saturday the 23rd ult. before the magistrates of Hayle, with having poisoned his brother some months since. Some circumstances having caused suspicion, the body was exhumed, and on examination it was thought that traces of poison existed. At present, however, nothing definite has been made public.

BEQUESTS.—The late Thomas Brown Young, Esq., whose personalty was sworn under 20,000*l.*, has left the bulk of it to charitable institutions, on the death of certain legatees. The charities named are—the Infirmary for Children (Waterloo road), the *Dreadnought*, Cancer Hospital, Infirmary for Asthma and Consumption (City road), Royal Free Hospital, East London Hospital (Victoria park), the Surrey Dispensary, and the Middlesex Hospital. Each bequest amounts to from 2,000*l.* to 4,000*l.*

MR. HOLMES COOTE has been elected corresponding member of the Society of Surgery of Paris.

NETLEY HOSPITAL RAILWAY.—The formation of a railway between Netley Hospital and Southampton will be immediately commenced.

ST. MARY'S HOSPITAL, MANCHESTER, which has hitherto been exclusively devoted to the treatment of diseases peculiar to females, has extended its field of operations by the addition of cancer wards.

MEDICAL MAGISTRATE.—Dr. Henry Hurry Goodeve, of Bristol, formerly one of the Professors of the Calcutta Medical College, has been appointed Magistrate for the County of Gloucester.

TYPHUS FEVER IN WHITEHAVEN.—The report of the Whitehaven Infirmary, just published, speaks favourably of the health of the town on the subsidence of the late attack of fever. The first four cases were admitted in January from various parts of the town. From March the fever continued to increase slowly, principally in the crowded and ill-ventilated houses of the poor. About the end of July it rapidly assumed the form of a wide-spread epidemic. It then gradually diminished in intensity, and there are now but few fever cases reported.

THE PHILOSOPHY OF TRAINING.—It is of paramount importance that we should bear in mind what are the whole results of training. That in one special direction great vigour is achieved, is true: and we, admiring this result, are too apt to generalize from it, and infer that in all directions the success has been equal. But it is not so. The muscular system has been forced into undue development, and this development has been at the expense of the general vitality. All forcing is injurions, except for the special object which is sought. The fighter has his muscular system in splendid condition; but his other systems are robbed to enrich that one; just as the nervous system of the student is in a state of intense activity at the expense of his muscles or glands. Nay,—and the fact is worth emphasis,—the powerful athlete is less able than the feeble student to stand the wear and tear of life. It was noted in Rome that the athlete were short-lived, liable as Sinclair admits, "to rupture of blood-vessels, to apoplexy, and lethargic complaints." and it has since been observed that not only do prize-fighters rapidly become aged and very rarely live long, but even the famous oarsmen of the Universities show a surprising mortality. It has been urged that the athletes and fighters are carried off by dissipation. Without claiming for such men any peculiar moderation, we must still claim for them that they are not more dissolute than their companions, who ought to succumb more easily to excesses if the popular notions about strength were accurate. But the truth is that the strength of a prize-fighter is to a great extent an abnormal condition, produced at the expense of the general system. The amount of vital energy which should be distributed among several organs has been so unequally apportioned that some are starved while others are overfed. It was known of old that for certain functions the athletes were almost totally incapacitated. That they have always been unfit for intellectual and moral activities is equally notorious. A man may have inherited a powerful brain with a powerful muscular system. The union is rare, but there is no physiological reason against it; there is, however, no possibility of even this man's preserving his intellectual vigour during a course of overstimulation of his muscles, all excess in one direction being compensated by a deficiency in the other. For perfect health both should be kept active, neither stimulated to excess. In the case of training, where, as we said, the object is to work up the muscular system to its highest pitch, the man may be magnificent to look upon and formidable to contend against, but he has been unfitted for the work of life, and is doomed to wither early. The training system is a forcing system; were it continued long it would kill; even for a brief space it is injurious. It is an exceptional process for an exceptional result, not the normal process for a healthy organism.—'Cornhill Magazine'.

BIRMINGHAM CHILDREN'S HOSPITAL.—The committee of this institution have placed some restriction on the admission of children. It is now required that the parents, previous to sending a child, shall make a statement as to the total earnings of the family, the number of children, &c.; and upon these data the admission of the child is made to depend. Since these regulations have been adopted a marked diminution in the number of applicants has taken place.

PROFESSIONAL DIGNITY IN FRANCE.—Our readers have not forgotten how certain parties have of late been summarily dealt with by the Medical Council and the College of Surgeons for unworthy conduct. A measure of the same kind has lately been adopted by the Academy of Medicine of Paris respecting a Medical man named Priou, practising at Nantes. This individual was a Correspondent of the Academy, and had lately, at the Medical Congress of Rouen, bills posted all over the town with advertisements of the most reprehensible kind. The members of the Congress protested very energetically, and the Academy has at last taken up the matter. It has been decided that Priou, for this forgetfulness of professional dignity, should be erased from the list of correspondents.

ODONTOLOGICAL SOCIETY.—At the annual general meeting held on the 4th ult., the following gentlemen were elected officers for the present year:—Edwin Saunders, Esq., President; Arnold Rogers, Esq., Treasurer; J. B. Fletcher, Esq., Librarian; Alfred Coleman, Esq., and Charles Vasey, Esq., Honorary Secretaries The President in his address congratulated the members on the present satisfactory condition of the Society, evinced by its numerical strength of 319 members, and the balance of 546*l.* 8s. 8d. in the hands of the Treasurer at the end of the last session.

EFFICACY OF THE SOLUTION OF ATROPIA IN SUPERFICIAL NEURALGIA.—The 'Bulletin de Thérapeutique' records a few interesting remarks of Professor Trousseau, on *Neuralgia*, in an extract of an unpublished chapter of the second edition of his 'Clinique Médicale.' We select a passage on the treatment of superficial neuralgia, in which the author recommends the solution of atropia as an external application; this preparation does not soil the skin or clothing like the extract of belladonna, and is prescribed as follows:—

℞ Atropiæ sulphatis, gr. iv.
Aq., destillatæ, ℥iijss.

Compresses impregnated with this fluid are applied to the seat of pain, covered with a piece of oiled sik, and secured with a ribbon or handkerchief. The aplication may be repeated several times in the course of the day, and on each occasion should be persevered in for an hour at least. If the pain be not relieved, the strength of the solution should be increased. When the neuralgia is fixed in one spot M. Trousseau advises the application with the tip of the finger several times in the space of an hour, of the following sedative:

℞ Atropiæ sulphatis, gr. iij.;
Aquæ destil, ℥ij.;
Alcohol rectif, ♏ xij.

When the neuralgia is situated in the scalp, along the course of the occipital nerves, for instance, the skin and roots of the hair should be moistened before the solution is used, a precaution which considerably facilitates its absorption.—'Journal of Practical Medicine and Surgery.'

THE COLNEY HATCH CHRISTMAS PARTY.—On Thursday week the managers of the Colney Hatch Asylum gave their annual treat to the inmates of that institution. Of the 1900 inmates, about 600, male and female, took part in the festivities. A great variety of entertainments were provided, and the complete success of the party was proved by the happiness it afforded to the patients.

MEDICAL OFFICER OF HEALTH FOR BIRKENHEAD.—At the last monthly meeting of the Birkenhead Commissioners, Dr. Charles Oliver Baylis was appointed Medical Officer of Health for the township. There were forty-six candidates for the office, of whom few possessed practical experience in sanitary improvements. Dr. Baylis, however, from his long residence in the borough, during which time he had taken an earnest and very active interest in the sanitary condition of the place, was unanimously chosen as especially qualified for the appointment.

GERMAN LADY-SURGEONS.—Frau Josepha Fey has just received a license to practise "lesser Surgery" in the Cologne district, on the condition that she should always act under the direction of a received Practitioner. This is the first example of such a concession being made to a woman in Germany.

ON PROTRACTED GESTATION.—Dr. Montgomery, in his work on "Signs and Symptoms of Pregnancy," records the case of a patient who had borne thirteen children, with

the last four or five of which she had exceeded her time by four to six weeks—that is, counting from the cessation of the menses: another of 291 days, and a third of 292 days. Harvey mentions an instance, where the woman carried the child for more than sixteen months, during ten of which the child was felt to move by herself and others, and at last she was delivered of a living child. Dr. William Hunter knew a woman who went fourteen days beyond the nine calendar months; Desormeaux relates a similar instance. Velpeau had a case of 310 days duration; Dewes of ten months; Burns of ten calendar months and ten days; Dr. Reid had two cases, one of 287 days, the other of 291 or 293. In the Gardner Peerage case gestation was prolonged to 44 weeks. Montgomery, in the work above quoted, notes two instances in which delivery took place in the 43rd week of pregnancy. Tessier and Lord Spencer have shown, that in the lower animals the period of gestation may be extended even to thirty or thirty-five days over the natural term. In Tucker's "Elements of Midwifery" it is recorded that 313 days was not an impossible period in the human female. Simpson mentions one of 314, or at the very least, of 290 days. Meigs had a case of fourteen months, or 420 days' duration,—see Simpson's Obstetric works, vol. I., page 340. Atlee gives a case in which the catamenia ceased on March 22, 1833; quickening took place on August 5, and delivery by the forceps was effected on March 22nd of the following year. It was a fourth pregnancy. Another, in which catamenia ceased August 6, 1832, quickening occurred on December 25, and delivery on August 13, 1833. Dr. Murphy met with a case where pregnancy had existed on two former occasions, and had been accomplished at the full time; however, the third time that the woman became enceinte, the menses ceased on February 10, 1861, quickening was noticed between the 10th and 20th of July; in November true labour-pains began, but were put back by a shock the patient received; on the 22nd of March, 1862, the child was born, "feeble and diminutive." The mother had been the subject of great anxiety while carrying the child. The same author mentions cases in which the gestation was prolonged to a term of 314 to 342, and of 324 to 352 days. The difference in the dates is caused by deducting a certain number of days, so as to allow for the uncertainty of the catamenial cessation.

DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.—Dr. Alexander Bryson, F.R.S., inspector-general of hospitals and fleets, has been appointed by the First Lord of the Admiralty to be director-general of the Medical department of the navy, vice Sir John Liddell, C.B., M.D., retired. Dr. Bryson became a surgeon in the Royal Navy Sept. 17, 1836, and an M.D. of Glasgow, 1837. He was surgeon of the 'Salamander,' 4, employed on particular service from 1837 to 1840; of the 'Madagascar,' 44, on the Coast of Africa, from August, 1841, to June, 1843; of the William and Mary, yacht, at Woolwich, from January, 1845, to the spring of 1847, and of the 'Fisgard,' 42, at Woolwich, from October, 1847, until promoted to deputy Medical inspector of hospitals and fleets, March, 1851. He was promoted to inspector general of hospitals and fleets, June 30, 1855. He is a corresponding member of the Academia Qurijica of Madrid, and author of a work "On the Climate and Diseases of the African Station," "Epidemics of Sierra Leone," "Statistical Reports on the Health of the Navy," an article "On Medicine and Medical Statistics," in the *Admiralty Manual of Scientific Enquiry*, &c. He has been borne on the books of the 'Fisgard' since October 24, 1847.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, FEB. 3. — *Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Dr. Garrod: "The British Pharmacopœia; its Construction, its Comparison with the London Pharmacopœia, and the Value of its New Remedies in the Treatment of Disease;" Obstetrical Society of London, 8 p.m.—Mr. Baker Brown, "On Fibrous Tumours of the Uterus treated by Surgical Means."—Mr. Bryant, "On Ten Cases of Ovariotomy; with Remarks."—Dr. Tyler Smith's "Additional Cases of Ovariotomy."

THURSDAY, FEB. 4. — *Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Tyndall, "On Experimental Optics," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia;" Chemical Society, 8 p.m.—Dr. How, "On Mordenite;" Harveian Society, 8 p.m.—Mr. W. Adams, "On the Pathology and Treatment of Fracture of the Patella."

FRIDAY, FEB. 5. — *Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Dr. Garrod: "The British Pharmacopœia; its Construction, its Comparison with the London Pharmacopœia, and the Value of its New Remedies in the Treatment of Disease;" Royal Institution, 8 p.m.—Mr. J. A. Froude, "On the Science of History;" Western Medical and Surgical Society of London, 8 p.m.—Mr. J. R. Lane, "Sequel of a Case of Vesico-Uterine Fistula, in which Pregnancy occurred after Closure of the Os Uteri by Operation."

SATURDAY, FEB. 6. — *Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, Mr. John Lubbock, "On the Antiquity of Man," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, FEB. 8. — *Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, FEB. 9. — *Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Three Hundred Consultations in Midwifery. By Dr. R. Lee. London: John Churchill and Sons, New Burlington street.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

THE GENERAL COUNCIL OF MEDICAL EDUCATION.—The paper has been received.

THE HARVEIAN SOCIETY.—The notice has been received.

THE OBSTETRICAL SOCIETY.—The notice has been received.

Mr. J. J. SKEGG.—The notice is inserted.

Mr. T. W. NUNN's paper has been received, and will be inserted in our next number.

Dr. G.—We regret that we are unable, from want of space, to insert the Report sent us of the eloquent address lately delivered in Dublin, by Dr. Stokes, in memory of the late lamented Mr. Smyly.

A STUDENT OF GUY'S—The necessary information may be obtained by application to the Secretary of the College.

X. Y.—We do not know the present address of the individual referred to.

FIRST YEAR'S MAN.—The effect of the Calabar bean on the pupil is exactly the reverse of that produced by atropia.

PARENS.—Five years; but this may include the whole term of professional education.

E. S.—The person first described would, we believe, be capable of holding the appointment; but whether he would have the preference to the other we cannot determine.

THE Clinical Report from the Royal Infirmary, Edinburgh, shall apper next week.

Dr. JOHN THOROWGOOD'S case shall appear next week.

C. S.—The P.O. orders are to be made payable to Mr. Thomas Rolfe, at the Charing cross Post office.

THE Report of the Meeting of the Harveian Society is unavoidably postponed.

Dr. KIDD'S paper on "Chloroform" shall appear shortly.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT'S Analysi gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxygen equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.

OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

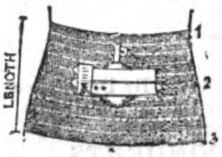
TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS

where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers,——Catalogues forwarded on receipt of Stamp.

BLOCKEY'S LONDON STOUT



NOURISHING LONDON STOUT

DR. HASSAL'S REPORT:—

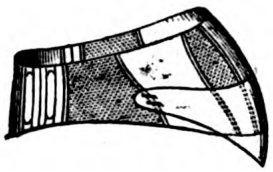
"I have carefully analyzed Blockley's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts. RAGGETT, late Blockey, 21 Duke st., St. James's Established 100 years.

MR. P. BOURJEAURD'S REGISTERED SPIRAL ELASTIC

BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 11 RUE DES DEAUX-ARTS PARIS.

Mr. PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in cases indicating their necessity, and begs respectfully to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating the necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatuses, Ankle, Knee and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 11 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies who may insure her attendance in Davies street, or at their own establishments, by favouring Mr. Bourjeaurd with instructions, according to their own preference.—Poor Patients are supplied at a reduction of thirty per cent. lower than the imitations.



AT HOME FROM TEN TILL SIX.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34 JERMYN STREET,

Beg to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELT, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

***** Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle. Directions for Measurement sent by post.**

N.B.—A Liberal Discount to the Profession.—A Female to attend on Ladies.

H. Silverlock's Medical Label Ware-

house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.

YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.

SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.

LABEL DRAWERS, for Dispensing Labels of various sizes.

A Set of Labels in accordance with the 'BRITISH PHARMACOPŒIA' now ready.

The Pneumoclime.—An Address to

the Profession, by Mr. JEFFREYS, on this his latest improvement the RESPIRATOR, and proposing another climate instrument, the PNEUMOTHALP.—Through a typographical omission, the above letter was printed without its Author's address—"Belvidere road, Upper Norwood, Surrey, S."

John W. Tweedie, Publisher, 337 Strand, is Chief Agent for the PNEUMOCLIME, in its several forms of Oral, Hand-Oral, Day and Night OrinaSals, and Nasal.

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 9s. 8d. Households (recommended for bread-making), 9s. 0d.; Seconds, 8s. 4d.; Wheat Meal for brown bread, 8s. 4d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

Whicker and Blaise, late Savigny

and Co., Wholesale and Retail Cutlers and Surgeons' Instrument Makers, No. 67 St. James's street, from Pallmall and King street, London, and at their Manufactory, Young's place, Wood street, Westminster.

Instruments made of the Laminaria

DIGITATA, Uterine Tents, see 'Med. Times and Gazette,' Nov. 28th 1863, page 558, T. G. Wilson, on Uterine Tents. Couper's dilating Uretha Bougies and Styles for dilating the Lachrymal duct, as used in the Royal Ophthalmic Hospital, Moorfields, may be had of C. W. KROHNE 241 Whitechapel road, London.

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by one in., and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON 89 High Holborn, London.

N.B.—Aquariums, Fern Cases, and Glass Shades.

Kamptulicon, Floor-cloth. — The

attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of Hospitals, Surgeries, Nurseries, &c. It is non-absorbent, quiet and warm to the tread, will not hold dust, is very easily and quickly cleaned, and will stand any amount of hard wear. It has already been adopted in several hospitals.

GOUGH and BOYCE, 12 Bush lane, Cannon street, London.

Original Patentees and Manufacturers.

Forwarded to all parts of the Country

The Medical Circular.

HOSPITAL REPORTS.

MIDDLESEX HOSPITAL.

A CASE OF UMBILICAL HERNIA OF LARGE SIZE.

(Under the Care of T. W. NUNN, Esq., Surgeon to the Hospital, with Clinical Remarks. Notes by Mr. Alfred Jones, Dresser.

May 5th, 1863.—M. B., mother of several children, a very stout woman, æt. fifty-seven, troubled with chronic cough. Admitted under Mr. Nunn's care, with a strangulated umbilical hernia, having a circumference of 21 inches; longest diameter, 14 inches; shortest diameter, 10 inches. Has worn a truss for thirty years. Awoke with pain on the night of the 3rd, found the hernia greatly distended, took much purgative medicine; application was made at the hospital late in the evening; at 10.45 p.m. Mr. Nunn operated (chloroform), the intense pain and other symptoms of strangulation rendering immediate interference requisite. The stricture was relieved by an incision being made through linea alba above the tumour, and then by dividing the constricting tissues by means of scissors, cutting down from the outside towards the tip of the finger introduced under the edge of the ring, through the opening in the linea alba, so as to avoid wounding the peritoneum of the hernial sac. On the following day cough was much complained of, the pulse 88. On the night of the 7th, the bowels were freely moved. Much of the hernial contents could not be returned, it ought to be stated, and though strangulation was removed by the operation, it was obvious from the size of the tumour that remained after, that much omentum and some bowel were adherent to the sac.

8th.—Much difficulty of breathing of an asthmatic nature coupled with some bronchitis, but with a feverishness disproportionate, in excess, beyond what these would account for. Pulse 120.

This fever was caused by the commencement of inflammation of the integuments over the hernia, which rapidly went on to gangrenous sloughing, but by the 19th, the notes say: The parts are looking much cleaner and patient sleeps pretty well. The greater part of the skin covering the hernia having sloughed away; cicatrization gradually progressed and materially contracted the tumour. At one or two points, the surface of the sore remaining, did not look quite satisfactory. However, one month after the operation, the notes say, the sore is healing, the cough is still very troublesome, and June the 7th the patient was sufficiently well to get out of bed, rather prematurely perhaps, as on the 8th, not so well; no appetite. 16th, Sick and restless. 19th, Better. 23rd, Much better, but the cough is very troublesome at night. 30th, Very much better. July 2nd, Feels much pain about the epigastrium and borders of the lower ribs. July 3rd, The legs are swollen, the wound made in the median line at the operation opened and much blood flowed. It is now over eight weeks since admission. Urine—scanty, turbid, sp. gr., 1030, no precipitate by heat and nitric acid. 5th, Fæcal matter escapes by two small openings on the surface of the tumour, at the point before referred to as looking less healthy than the rest of the granulating area. Patient only semi-conscious. 9th, The power over the right side is lost. 10th. Died at 8.45 p.m., sixty days after operation.

Post-mortem revealed tubercular peritonitis, general; liver fatty, weight 4lb. 5¼ oz., a yellow tubercular mass at the right extremity of the transverse fissure. The hernial sac contained chiefly fat derived from omentum, with a small portion of colon (whence the escape of fæcal matter). A transverse section of hernial contents on the right side presented some softened tubercular (?) yellow deposits. Kidneys, cystic to an extensive degree, right, 8¼ oz., left, 7 oz. Spleen, mottled on surface, deliquescent. Heart, flaccid, fatty, vegetations on the mitral valves towards their bases.

Remarks.—Recovery after operation for strangulated umbilical hernia is quite the exception. The probable explanation of this circumstance lies in the fact, that the subjects of umbilical hernia are generally very fat, speaking of those that present themselves at hospitals with their hernia strangulated; and are females past the prime of life. The above case is one of this kind, the heart was fatty and otherwise structurally altered, the liver was in a similar pathological state, and I may here mention that, in severe operations, involving the peritoneum; such as for example ovariotomy, a fatty condition of the liver is too likely to lead to a fatal result. Looking at the amount of visceral disease of a chronic nature, it is almost to be wondered at, that this patient was able to not only survive the severe tax on constitutional powers involved in the sloughing of the integument of the sac, but to supply the vital energy required for the almost complete cicatrization of the extensive sore produced. It is difficult to understand how such intense inflammation could have existed in the integument of the sac, without lighting up acute peritonitis. It is equally difficult to explain how the peritonitis that did exist was so modified as to be of the tubercular form. There can be little doubt that there was peritoneal inflammation of this subacute character going on, even when matters looked most hopeful, when one almost made sure of a recovery. The great trouble all through the case was the cough. It is useless to occupy space with details of treatment that was useless, suffice it to say that all that others who saw the patient could suggest was tried without any obvious effect on the cough, which possibly might after all have been due to reflex irritation.

ECCENTRIC EPILEPSY,

(Under the care of DR. GOODFELLOW.)

(Reported by C. W. PITT, Senior Resident Clinical Assistant.)

Henry W——, admitted into Founder Ward, Jan. 13th, 1863, a pale, thin, weakly boy, naturally irritable and excitable. He never had fits before admission; has been subject to worms. A brother of the patient had fits during dentition, and an uncle had also suffered from them. After partaking largely of herring at breakfast, he began to feel sick, and was indisposed all the day until five p.m., when, leaning out of window, he had a sudden attack of nausea, followed by a headache, then became insensible, and in a few minutes had a series of convulsive fits, which continued until he was brought to the hospital.

State on Admission.—Strongly convulsed; frequent jactitations of arms and legs; often striking his chest with clenched hands; features distorted; slight foaming at the mouth; pupils dilated, and do not answer to light; skin warm and perspir ng; pulse 108, full, and not very compressible; no involuntary discharge of fæces. In a short time these convulsions ceased; he then lay totally insensible, and had occasional twitchings. Ordered:

Enema oleosum, statim.

14th. Ten. a.m. Between four and five, a.m. he became sensible; still with some clenching of fingers and carpho-

logy; complains of some frontal headache; pupils somewhat dilated; surface of the body warm and dry; face flushed; lips dry; tongue moist and coated, with an unpleasant taste in the mouth; some appetite, no thirst; pulse 94, soft and compressible; respiration 24, tranquil, chiefly thoracic. This morning he had a small bilious motion, containing scybala. Urine pale, turbid, sp. gr. 1005, acid no albumen, contains some phosphates.

Pulv. jalap co., ℈j., statim.
Lot. spirituosa capiti.

15th. Lies quite composed; slight twitchings of the extremities still present; no headache; pulse 80, moderately full, and compressible. Bowels moved once since the powder.

16th. Continues to improve; only slight twitchings.

20th. Discharged well.

UNIVERSITY COLLEGE.

(Cases in the Wards under the care of Mr. ERICHSEN.)

The child, on whom Mr. Erichsen operated for stone a little time since, is now quite out of the hands of the surgeon, the wound being completely united, at least so much so that there is no escape of urine through it, that fluid being for some days past, expelled per urethram.

The first case, which Mr. Erichsen visited was that of a man, who, sometime previously had received a comminuted fracture of the leg; great ecchymosis had resulted from the violence whereby the fracture had been produced, and the leg presented these conditions when the patient was admitted into the hospital.

Bullæ subsequently had formed in various places upon the leg, and were probably the sequence of the great distension, which was occasioned, no doubt, by the extravasation of blood into the subcutaneous tissues. These bullæ were punctured, and an exit afforded to their liquid contents; at the site of one of them, however, the integuments beneath it had given way, and the *simple* comminuted was thus converted into a *compound* comminuted fracture. The cause of the integumentary death was found to be the same as had given rise to the formation of the bullæ, namely, the extravasation of blood, great consequent distension of the skin, a lessening of its vitality, and finally its death.

The fracture had been put up in perfect apposition, and the several fragments had been similarly maintained, so that no harm had been done to the tissues by any projecting or misplaced bones or fragments of bone.

After the wound in the soft parts had been effected in the manner above described, a light linseed poultice had been placed over the leg as it rested in the fracture box; this plan of treatment was adopted because of the swollen state of the limb from the effused blood and because of the suppurative tendency of the wound; its objects being fulfilled, it was then laid aside, and warm lead lotion was used in its stead, lint dipped in the lotion being applied, and then covered with some oiled silk, in order to prevent evaporation, and so to keep the injured parts in a kind of constant vapour bath.

Reduction of the great swelling, and tension and closure of the wound are being thus effected, while at the same time, the broken bone is becoming united.

To use the words of Mr. Erichsen, "this injury is not only far more tedious in its cure than simple fracture, but infinitely more dangerous. The tediousness depends upon the communication of the fracture with the external air, causing it to unite by a slow process of granulation, instead of by the more speedy adhesive action that occurs in the simple form of injury. The danger is likewise partly due to the same cause; the process of suppuration and granulation being often attended by such profuse discharge of pus from abscess or long continued exfoliation of bone, or by the supervention of secondary disease, such as, hectic, phlebitis, pneumonia, or erysipelas, as to lead to the eventual loss of limb or life. Besides these dangers, which may be looked upon as a remote kind, the violence that occasions a compound fracture, often shatters the limb to such an extent, as to lead to the immediate supervention of traumatic gangrene, to the loss of life by hæmorrhage or, to the certain and speedy disorganisation of the limb as the consequence of the re-actionary inflammation."

The favourable points in this man's case are: first (though the tissues are infiltrated with blood, and this infiltration is the result of the violence, which occasioned the fracture), the wound is not very large, nor has it been primary, that is, produced at the time of the accident moreover, the broken bones have been throughout kept in their proper position, and there has been no large vessel wounded—no nerve injured.

In the next bed was a middle-aged man, the subject of iliac abscess. The peculiar feature of this case was that the man on presenting himself for admission was bent, or doubled up, but in such a manner as to leave it doubtful whether the body were curved downwards and forwards, or the thigh and leg upwards and forwards.

He was put under the influence of chloroform, the limb was stretched, and an abscess detected deep in the iliac fossa; as soon as this pointed, which it did a few days after he had been in the house, an opening was made into it. The pointing took place a little below Poupart's ligament.

Abscess in the groin, says Mr. Erichsen "may arise from the following causes:—first, from large lymphatic collections in the subcutaneous or inter-muscular planes of cellular tissue; secondly, from disease of the cellular tissue around the kidneys; thirdly, from pericæcal abscess on the right side only; fourthly, from iliac abscess, whether forming merely in the iliac fascia, or dependent on disease of the pelvic bones; fifthly, from hip-joint disease, the abscess being pelvic; sixthly, large buboes, or glandular abscesses; seventhly, from an empyema, perforating the pleura, and finding its way down behind the diaphragm."

We should be careful to diagnose the iliac from the psoas abscess. The points of diagnosis are these:—In the latter there will be pain experienced in the dorsal region of the spinal column, either on pressure or the mere motion of the body; the spinal column will be found in many—not all, cases, more or less curved; the affection exists usually in childhood and youth; there will be manifestations of muscular irritation, and sometimes a spastic rigidity of the limb; the site of pointing is most frequently below Poupart's ligament; the abscess very often presents itself quite suddenly.

The iliac abscess most commonly exists in adults, or those who have passed the meridian of life, is occasioned by blows, strains, cold, or constitutional delicacy; in women by parturition; or by disease of the corresponding innominatum; it comes on gradually, and points not in the upper part of the thigh, as is the case in psoas abscess, above Poupart's ligament; nor does it point so definitely being diffused and less circumscribed.

There is a difference also in the pathological conditions the psoas abscess, besides being connected with disease of the spine, is to be found in the sheath of the psoas muscle, whereas the iliac, connected with disease of the bone, clothed by the iliacus muscle, is situated between the peritoneum and the iliac fascia, or the fascia and the muscle.

The psoas abscess may likewise be felt, especially if the person be emaciated and the abdominal walls be flaccid, along the course of the psoas muscles; as the iliac abscess may be detected in the iliac fossa, unless, indeed, it should have made its way into the sheath of the psoas muscle, which so complicated very much the diagnosis.

There is a form of paralysis attendant upon the angular or Pott's curvature of the spine—a disease which is the most common cause of psoas abscess—that is termed spinal, because the muscles are contracted in such a manner

as to flex the leg upon the thigh, and the thigh upon the pelvis.

This palsy is rather from irritation than from pressure, as is evinced by the character it assumes, as well as by its being removed or diminished on the formation of abscesses.

In perinephritic abscess, that is, abscess occurring in the fatty renal capsule of Cruveilhier, there will be, of course, symptoms indicative of renal affection; while in the perityphlitic, there will be more or less intestinal irritation and great fetor of the purulent discharge. Abscess from hip-joint disease will be readily diagnosed by the condition of the parts, which are the fons mali. Empyema is known from the stethoscopic symptoms that will be present.

In another bed was a young child also labouring under iliac abscess, which had, however, opened above Poupart's ligament, and which was being emptied gradually by means of a drainage tube. In this latter case, there was no doubt as to the nature of the disease, inasmuch as all the characteristic features were well marked.

Passing on we came to a patient, whose leg, a little below the knee-joint, had been removed for gangrena senilis, and who is doing remarkably well, not a single untoward symptom having arisen since the operation, which had been performed some weeks since. The wound is perfectly healthy, and healed almost throughout.

"The broad question of amputation in cases of gangrene, turns upon the fact of the mortification being local or constitutional in its origin. When the constitutional disease is the primary affection, and when the gangrene is consecutive to, and dependent upon this, it would clearly be useless to cut off the mortified part, as the same morbid action might and would be set up in the stump or elsewhere."

We should bear in mind, in these cases, never to operate till the line of demarcation have been well established and have existed for some days; otherwise we shall have a renewal of the disease in our incision. The cause of this recurrence is to be found in the very low vitality, not of the limb alone, but of the constitution generally, and which is unable to create a healthy inflammation or to sustain healthily the reactionary condition, induced in the affected parts, by the operation.

During the formation of this line of demarcation, and while the process of separation by ulceration is going on between the healthy and unhealthy structures, we must give our patient every support in our power, so as to enable Nature to complete the efforts for cure, which she has begun; then when we have satisfied ourselves that we have given to the system a certain degree of tone and vigour, that amount, necessary for the throwing off the diseased parts and the establishing of healthy action in the stump, and when "all the soft parts, except the ligaments, have been ulcerated through, the mortified parts should be separated by cutting through the remaining osseous, ligamentous or cartilaginous structures, and then means should be taken to fashion the stump that has been formed by Nature. In some cases this will be sufficiently regular to serve every useful purpose after it has cicatrised; in most instances, however, it will be found that the bones protrude to such an extent, or that the ulceration has affected the soft parts so irregularly that it will be necessary, in order to give the patient a useful limb, to amputate through the face of the stump, or higher up; all this, however, must be left to the discretion of the surgeon."

Some surgeons advise to leave the entire amputation to Nature, and that, even if the dead parts were hanging on merely by a few shreds of tissue, these shreds had *better not* be touched, lest the gangrene be lighted up afresh.

There is a case noted by Sir Astley Cooper, in which the process of spontaneous separation was proceeding most favourably; the bones, however, were projecting and preventing the healing of the wound; they were accordingly worn off, some small vessels in the granulations were wounded, hæmorrhage resulted, and ultimately proved fatal.

Mr. James, of Exeter, and Mr. Garlike have successfully removed the diseased parts, by operation practised high up in the thigh; but the health must be good, the constitution not tainted, and the affection purely local, dependent upon obstruction of the arteries, rather than the local development of a constitutional disease.

In another patient there had been deep-seated abscess in the adductor muscles, which was opened—first, by making an incision into the integuments, and then by passing a probe through the muscles into the abscess; in this way a channel was made for the matter to pour out, and the man did very well for ten days or a fortnight, when suddenly, at the end of that time, blood flowed freely from the wound, and had to be checked by plugging, combined with pressure. Since then the patient has been doing very well.

The next was a man, who ten years since had met with a fall upon the hand, which occasioned him very severe pain, but at the time had not resulted in anything more serious. He was now, however, suffering from a very rare form of disease—namely, abscess in, and disease of, the bones at the sterno-clavicular articulation. The health enjoyed by the patient was most excellent, despite the existing affection.

On firmly grasping and then moving the shoulder, a very distinct crepitus could be detected, referrible to the sterno-clavicular articulation, and on probing the wound, the bones were found to be bared of their periosteum, and to be rough and rugged. This case Mr. Erichsen pointed out to be of special interest; first, because of the rarity of the disease in any condition of the constitution; and, secondly, because of its occurrence in a man otherwise perfectly healthy.

The treatment adopted is that of bandaging the arm to the side, with the view of procuring anchylosis, so effecting consolidation of the joint, and giving to the man a comparatively useful limb.

Mr. Erichsen teaches that there are two kinds of anchylosis: the incomplete, or fibro-cellular; and the complete, or osseous.

THE ROYAL ORTHOPÆDIC HOSPITAL.

Mr. Brodhurst divided the flexor tendon of the ring finger of the right hand in a woman, who about a month since had stuck a pin into the top of the finger. The accident was followed by the formation of matter and subsequent contraction of the finger.

Passing the tenotome from his right to his left hand and *underneath* the contracted tendon, as it ran along the palmar surface of the proximal phalanx, he proceeded to divide it by turning the edge of the instrument to the tendon, and by then using a very gentle sawing motion.

The knife, which is long, fine and narrow-bladed, must be introduced horizontally—that is, its flat surfaces must look one towards the bone, the other towards the integument of the phalanx which corresponds to the site of division, and having been then made to dip beneath the tendon the edge is turned upon the latter, which is then rendered completly tense by traction on the incurvated finger, and in this manner division is effected.

A piece of lint is placed upon the wound and made fast by means of a strip of adhesive plaster, the finger is allowed to remain bent as before the operation, and the entire hand is then enveloped in a bandage, the thumb being allowed to be free.

The straightening of the finger is a future step of the proceeding, and must be accomplished gradually.

Mr. Adams then divided the tendo achillis in a boy of about seven years of age, who *now* had talipes equinus. Upon a former occasion the same gentleman had operated on the patient for talipes varus, which he had, in fact, converted into the deformity that now presented.

He stated that there are two stages in the operation for varus; in the first the tibialis anticus and posticus tendons, as well as the long flexors, must be divided, and the foot inclined outwards by means of a straight splint running along the outer aspect of the leg. In the second step the remaining deformity, namely, the talipes equinus, is removed by division of the tendo achillis and by the use of Scarpa's shoe after the lapse of two or three days.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B. M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

Before commencing a systematic and detailed review of the novelties and alterations which have been introduced into the British Pharmacopœia, we think it advisable to take a rapid glance at the more prominent changes which have been made in those preparations which are most frequently prescribed by the Medical practitioner. In this list we may class the dilute mineral acids, decoctions, extracts, infusions, and tinctures.

Turning, then, to the dilute mineral acids, we find that the strengths of all these have been more or less changed. They are now, indeed, in one respect, of an uniform strength —that is, six fluid drachms of these dilute acids now contain one equivalent of the acid. This change, regarded from a chemical point of view, may appear to offer some advantages; but as doses are not regulated by chemical equivalents, they may at first rather confuse the prescriber. The alterations in the strength, however, are not great, and the practitioner will hardly find it necessary to make much change in the doses. The strengths of the dilute acids will be best shown by a tabular statement of the specific gravities of the old and new preparations.

	Specific Gravity.	
	Old.	New.
Acidum Hydrochloricum dilutum	1·043	1·050
„ Nitricum „	1·082	1·101
„ Sulphuricum „	1·103	1·087

By the above table it will be seen that the dilute hydrochloric and nitric acids have been a little increased in strength, while that of the dilute sulphuric acid has been slightly diminished. In the case of dilute nitric acid, the proportion of acid and water given would, at first sight, seem to indicate a reduction of strength; but it must be remembered that the density of strong nitric acid in the British Pharmacopœia is 1·5 instead of 1·42 as in the London. The greatest change has been made in the use of dilute sulphuric acid, the strength of which has been reduced, but not so far, perhaps, as to necessitate any increase in the dose. It will be well to mention at once that the strength of acid. hydrocyan. dil. remains unaltered.

Passing rapidly on we come to the decoctions, the first of which, Decoctum Aloes Compositum, shows a considerable alteration. In the decoction of the London College ninety grains of aloes were contained in twenty-seven fluid ounces of the finished preparation. In the British Pharmacopœia the same quantity of aloes is ordered in sixteen ounces of the compound decoction; the strength of this preparation, therefore, has been nearly doubled. The remaining decoctions call for no remark.

In the extracts, several changes have been made in the mode of preparation, and most of them may be regarded as decided improvements. The extracts of Aconite, Belladonna, Conium, and Hyoscyamus, are now directed to be prepared by a process which has long been recommended and, indeed, followed by some of the best makers of this class of preparations; and the result will be extracts of improved appearance, that will keep much better than those which were prepared strictly according to the old directions. Some liquid extracts have been, and more might have been, added, with advantage. Among liquid extracts we might class the preserved juices which now find their place in the Pharmacopœia. Those introduced—namely, of Conium, Scoparius, and Taroxacum, have long been in use, and are largely prescribed, and it is well to have authoritative directions for their preparation.

Among the infusions we notice many changes, but miss some things which were expected, and are certainly required. We allude to formulæ for concentrated infusions. These articles are largely used, and may be said to be necessities with the general practitioner; and although the makers of these preparations may, no doubt, be relied on to furnish articles which, when diluted, will fairly represent the infusions desired, it would have been better to have had authorised formulæ.

The compilers of the Pharmacopœia may regard such infusions as uncertain in their strength, but the Profession have long been accustomed to these inconvenient preparations, and therefore it would have been well to have adopted them, and to have given directions which would have ensured uniformity of composition and appearance.

Some changes in the mode of preparing infusions are decided improvements. In the infusion of calumba, the Dublin mode of making it with cold water has been adopted. The infusions of gentian and quassia are also made with cold water, and the strength of the latter greatly increased, or perhaps it would be more correct to say, that the amount of quassia ordered is much larger.

Among the Pilulæ we do not find much for comment. English prescribers must now remember that there is both an Extractum Colocynthidis Compositum, and a Pilula Colocynthidis Composita, differing considerably in composition. The present extract will be much the same preparation as that called Pilula Colocynthidis co. in the London Pharmacopœia, while the Pilula Coloc. co. of the British Pharmacopœia is the preparation of the Edinburgh College. These articles will, perhaps, serve as good examples of the compromises which the compilation of a Pharmacopœia for the three kingdoms has necessitated.

In the preparation of the tinctures an important change is introduced, at least, as far as English Pharmaceutists are concerned. By the adoption of the process of percolation or displacement, a step no doubt has been taken in the right direction. Only comparatively a few tinctures

in future, to be prepared by simple maceration; in fact, only those to which, from the resinous and soluble nature of the ingredients, the method of percolation would be inapplicable.

That great uncertainty and inconvenience have resulted from the process hitherto ordered, there can be no question; although, when conscientiously performed, an unexceptionable result was obtained. The necessity for waiting seven days was in itself an evil. A dispenser who had run out of a certain tincture which he required, and of which, perhaps, a fresh batch had only been put on a day or two before, was sorely tempted to draw upon it before the expiration of the prescribed time; while, on the other hand, it probably frequently happened that, as the tincture was not wanted, it remained macerating for a week or a fortnight longer than it should have done, the Pharmaceutist consoling himself by the reflection that the extra time would make up for the total want of shaking it had experienced.

Of those tinctures which are still to be made by maceration, there is one point worthy of note. The instructions are to "macerate for seven days, strain, express, filter, and add sufficient spirit to make one pint." The latter direction is new, and appears likely to cause discrepancy. A tincture made in small quantity, and of which a good deal has been lost in pressing and filtering, may, when made up to the required bulk differ in strength from one made in large quantity with little loss.

In performing the process of displacement, we are ordered to macerate the ingredients "for forty-eight hours, with fifteen ounces of the spirit, in a close vessel, agitating occasionally, then to transfer to a percolator, and when the fluid ceases to pass, to pour into the percolator the remaining five ounces of the spirit. As soon as the percolation is completed, subject the contents of the percolator to pressure, filter the product, mix the two liquids, and add sufficient proof spirit to make one pint." While we commend the introduction of the principle of percolation, we cannot entirely approve of the manner in which the process is to be conducted. The preliminary maceration for forty-eight hours is certainly not necessary in a large number of cases, and it will cause a considerable amount of trouble. For instance, no one, we should think, would deem it necessary to macerate ginger, when such perfect exhaustion may be obtained by putting the dry powder into the percolator. The British Pharmacopœia includes eleven tinctures which are new to English pharmacy, namely, the Tincturæ Arnicæ, Bucco, Cannabis Indicæ, Chiratæ, Cocci, Croci, Krameriæ, Nucis Vomicæ, Sabinæ, Senegæ, and Stramonii. Of these, four are new to all three colleges,—the Tincturæ Arnicæ, Sabinæ, Senegæ, and Nucis Vomicæ.

The most notable changes in strength occur in Tinctura Aconiti and Tinctura Belladonnæ. The former is one-third the strength of the old Tincture, and the latter one-half.

An important alteration is also made in Tinctura Ergotæ, which is now prepared with proof spirit instead of ether, as formerly.

Many slight alterations in the proportions of constituents have apparently been rendered necessary by the change in the system of weights.

This is illustrated in the case of tincture of opium which, though apparently retained unaltered is really weaker. The London College ordered three ounces of opium to two pints of spirit. The New Pharmacopœia orders one ounce and a-half to one pint. But the new ounce contains 42.5 grains less than the old, consequently there is about a drachm less opium in the pint of new tincture. The same cause operates to a greater degree in the case of Tinctura Colchici.

Such is a brief review of the changes made in the most commonly prescribed medicines. In future articles on the Pharmacopœia, we propose to give extended critical notices of the various processes by which the several preparations are obtained, and of the methods employed for ascertaining their strength and purity.

A NEEDLE SWALLOWED, AND MAKING ITS WAY THROUGH THE WALLS OF THE ABDOMEN.

Dr. Frederick D. Lente relates the following case in the 'American Medical Times':

"I was called to a little girl, about seven years of age, a few days ago, under the following circumstances: Five months ago, during the month of July, she said to her mother that she had swallowed a pin; but, as no unpleasant symptoms supervened, the occurrence was soon forgotten, and nothing more was heard of the pin until a few days ago, when she complained that, on stooping down, something pricked her in the belly; and upon feeling with her fingers she discovered what she supposed to be the forgotten pin: upon examining the spot, which was a few inches below the umbilicus, after some manipulation I managed to get the two ends of the substance between two fingers, and, on pressing one end outwards forcibly, the point of what proved to be a needle an inch and a half in length projected through the skin, and was drawn out by a pair of forceps. It was blackened and very brittle. No unpleasant consequences have resulted. In connexion with this case I would call attention to No. 67 of the Pathological Museum of the New York Hospital; a boy's heart, *the septum ventriculorum* of which is transfixed by a needle. It appears not to have produced any serious consequences. The boy died of a wound of the subclavian artery. I knew an old gentleman some years ago, who was engaged in a large mercantile business. He suffered for twenty or thirty years with "neuralgic pains," so they were called, in different parts of the body, for which but little relief was obtained, and from which his constitution suffered very much. One day, while writing in a private room of his establishment, and rubbing his knee, which was, at the time, the seat of one of his neuralgic attacks, suddenly, to his great surprise, the point of a needle popped out of the skin. Before endeavouring to pull it out, he called in some of his clerks to witness the phenomenon. He never afterwards suffered from any of his former attacks; and, at the time I saw him, enjoyed good health."

Dr. TURNBULL.—Surgeon Turnbull, of the 6th Dragoons, has been tried by Court Martial since the Crawley case, and, like his chief, has been "honourably acquitted."

LEEDS INFIRMARY.—The foundation stone of this edifice is to be laid on Easter Tuesday, March 29th, by Mr. Kitson, Chairman of the Building Committee.

NOTICE.

As soon as the British Pharmacopœia saw the light, we made our readers acquainted with the general nature of its contents, and we have, from week to week, continued to impart information as to the changes which have been made in the new volume as compared with the former Pharmacopœias. As the whole aspect of Pharmacy is modified, however, by the recent alterations, and as it is incumbent on all the members of the Profession, as well as on all persons practising Pharmacy, to be made thoroughly acquainted with the contents of the British Pharmacopœia, we have determined to publish a series of original articles upon the drugs introduced, and on the processes for preparing them, together with their uses in Medicine, and their doses. In order to give to these articles the highest scientific value, we have placed the whole of the chemical details which are involved, under the superintendence of Dr. HENRY LETHEBY, who, in conjunction with the Editorial Department of this Journal, and with experienced assistants in chemical and pharmaceutical processes, will conduct the publication of the series. In thus announcing the name of the gentleman who will institute these investigations, we offer the best guarantee, not only for the scientific value of the articles, but for the fairness and impartiality which will be shown to the pharmaceutical body. No attempt will be made to bring into undue notice the preparations of any particular pharmaceutist, but we shall be happy to receive information from any of the members of that body who may wish to make known any particulars as to the processes they employ, or the improvements they may have introduced into practical pharmacy; and we shall also be open to receive practical opinions upon the merits or demerits of the processes recommended in the new volume now offered by the Medical Council to the Medical Profession and to the practitioners of Pharmacy throughout the British Empire.

THE MEDICAL CIRCULAR.

WEDNESDAY, FEBRUARY 10, 1864.

THE BRITISH PHARMACOPŒIA.

As the Profession will no doubt be anxious to receive the earliest information as to the points on which the British Pharmacopœia differs from the Pharmacopœias hitherto in use, and as to the new remedies now introduced into one or other part of the British Empire, or presented for the first time in Medical practice, we hasten to give a condensed view of the remarks just made by Dr. Garrod, in his lectures delivered during the last week at the London College of Physicians. We have previously observed that many apparent novelties are not really such, but that the introduction of some drugs hitherto recognised only by the Dublin and Edinburgh Colleges, gives an air of strangeness to some of the articles in the British Pharmacopœia. Many of the substances thus introduced are of very questionable, or more than questionable value.

The oxide of silver, which it may be recollected was very much extolled in certain gastric affections by the late Sir James Eyre, finds a place in the new volume. It appears to be useful in some forms of gastric disturbance, and perhaps in some convulsive diseases, in the dose of gr. ¼ to gr. ½, or gr. j., but its superiority over the nitrate is not very manifest, and there seems to be no reason for believing that its long-continued use would be less liable than that of the salt just named, to cause discoloration of the skin.

Bela is the name given for the substance called Bael, obobtained from the Ægle Marmelos, a plant of the natural order of Aurantiaceæ. It is very much employed in India, and is considered in that country as almost a specific in diarrhœa and dysentery. It appears to contain some tannic acid, and is therefore astringent, but Dr. Garrod has not found it superior to other astringents used in this country, and, indeed, it has failed in cases where other similar remedies have succeeded. It is used in the form of an extract.

Belladonna, although long known and valued as an article of the Materia Medica, appears in a new form, and Sulphate of Atropia is omitted. The Extract of Belladonna is an awkward form for external use, and the Sulphate of Atropia is very dear, but the Tincture of Belladonna is now introduced as a clean and efficient application, and a liniment, prepared from the root, may be employed as a local anodyne.

Chirata is the name given to the Chiretta, a plant belonging to the natural order of Gentianaceæ, and endowed with properties analogous to those of gentian, to which it does not appear to be in any way superior.

The Cocculus Indicus has been, as we remarked last week, a most injudicious and useless intrusion, and Dr. Garrod made the same remarks upon it as we used ourselves. It is a poisonous plant, owing its properties to the presence of a powerful alkaloid called *picrotoxia*, and appears to act upon the medulla oblongata. It is supposed to be used in the adulteration of beer, or if it is not so used it is difficult to understand why so much is imported into this country. Its presence in the British Pharmacopœia is perfectly inexplicable, as its only known use is to destroy lice, and the very fact of its being supposed to be employed in medicine must lend a kind of colourable pretext for the sale of a most noxious drug.

The Cannabis Indica has better claims to notice, as the

alcoholic extract and the tincture are possessed of well-marked, and to a certain extent, valuable properties, although the chemical composition of the plant is not well-known, the active principle (if there be any) has never been discovered, and the effects are somewhat uncertain. In India a large quantity of this plant is used in order to produce a species of intoxication, and the substance so used is the *haschisch*. In this country the chief employment of the Indian hemp is in the treatment of neuralgia, in which disease it appears to act as a sedative. It is not, properly speaking, narcotic, and causes sleep only indirectly by allaying nervous pain. The dose is from ¼ gr. to 1 gr. of the extract, and ℥v. to ℥xx. of the tincture.

Digitalin is another introduction of doubtful value. This substance is the active principle of digitalis, and possesses, although in a far more concentrated degree, the properties of that plant. It is now known that digitalis may be given in much larger doses than was at one time thought to be safe, and therefore digitalin may not be so dangerous as might at first be supposed, but it possesses no advantages whatever over digitalis itself, and is moreover very likely to be adulterated, owing to its scarcity and its high price. *Digitalin is* a powder, and the dose is the one-fiftieth of a grain.

Iron is of course well-known in medicine, but several forms of it appear as novelties in the Pharmacopœia. In the first place the metal itself is introduced as Ferrum Redactum, the metal being reduced from the oxide by the aid of hydrogen gas. Dr. Garrod thinks very highly of the metal employed in this state, as it is the most powerful of all the ferruginous preparations, is easily dissolved in the acids of the stomach with the evolution of hydrogen gas, and is not very astringent. The dose of one grain is equivalent to five grains of the citrate of iron and quinine. The magnetic oxide of iron is not so valuable, as its efficacy is doubtful; the dose is from two to five grains. The hydrated peroxide of iron is used solely as an antidote, or supposed antidote, in cases of poisoning by arsenic. The phosphate of iron may be efficacious as combining the beneficial effects of the metal with those of phosphoric acid, and the more so as phosphate of iron exists in the human system. In connection with iron, Dr. Garrod made some remarks on Manganese, a metal very analogous to it in its chemical relations, and which has been supposed to possess similar therapeutic properties; but it has not been introduced into the new Pharmacopœia, and Dr. Garrod thinks that it is not superior to iron, and, indeed, that it is less efficacious as a tonic.

Glycerine is a very useful substance as an external application, and as an excipient for more active drugs. From its sweet taste it may be used to sweeten articles in cases where sugar disagrees, or where its use is objectionable, and it has sometimes been proposed as a substitute for cod-liver oil. But Dr. Garrod has determined, by experimental investigations, that it does not possess the remedial power of the oil in those cases in which the latter is most efficacious.

Fel Bovinum, or Ox Gall, is recommended as an internal remedy in some cases where the secretion of bile is deficient. It is obtained from the bile of the ox, and exists in the form of a powder, the dose being from three to five grains. Dr. Garrod does not commend this article as a medicine, or indeed any other secretion obtained from a brute, and he therefore approves the omission of pepsine from the Pharmacopœia He doubts whether such articles really supply the want of the natural human secretions.

Podophyllin is the resin obtained from the Podophyllum peltatum, a plant of the natural order of Ranunculaceæ, and is presented to us under the name of Podophylli Resina. This is really an active and useful medicine, being a brisk purgative and causing a copious discharge of bile. It appears, however, that it does not act by increasing the secretion of bile, but merely by emptying the gall-bladder. Its inconveniences are that it often causes griping, followed by great depression, and it is best to combine it with other purgatives, and with some sedative, as belladonna or henbane. The dose is from gr. ¼ to gr. ½ up to gr. ij, and it may often be used in place of mercury.

Among the spirituous preparations, the Spiritus Ætheris Compositus, or Hofmann's Anodyne has disappeared to make way for the Spiritus Ætheris. The difference consists in the omission of the ethereal oil, which is dear, liable to decomposition, often adulterated, and not *proved* to possess any antispasmodic properties. The spiritus Chloroformi is the same preparation as that which has hitherto erroneously passed under the name of Chloric Ether, which latter is of very variable composition in different establishments. The Spiritus Chloroformi has a definite composition of one part of chloroform to nineteen of spirit. The Spiritus Ætheris Nitrosi is now for the first time a definite compound of nitrous ether and spirit, instead of being, as heretofore, an indefinite mixture of spirit, nitrous ether, aldehyde, and acetic acid. It is directed to be prepared from the nitrite of soda. Pyroxylic spirit or the hydrated oxide of methyle is an introduction of a very questionable character, as methylated spirit (under which name is understood spirit of wine spoiled by admixture with wood spirit) is already largely used for purposes of adulteration. Pyroxylic spirit has been supposed to be useful as a sedative in allaying cough, but Dr. Garrod thinks that any efficacy it may possess is in reality due to the creasote compounds which it may accidentally contain, and that on the whole it ought not to have been introduced into the Materia Medica.

The class of Anthelmintics comprises four substances more or less new—namely, the liquid extract or oil of male fern, the Kamela, obtained from the Rottlera tinctoria, an Enphorbiaceous plant, the Cusso, or Kousso, obtained from the Brayera anthelmintica, and Santonine, obtained from the flowers of a species of Artemisia. All these substances have, however, been long used, although not in Great Britain. The flowers of Santonica have been employed under the name of *semen contra*, but they are too bulky, and the active principle or santonine is an excellent substitute in the dose of five or six grains.

The lauro-cerasus, or cherry-laurel, is a poisonous plant, so far as the leaves and kernels are concerned, and ought not to have found a place in the Pharmacopœia, for cherry-laurel water is an uncertain compound, containing variable proportions of prussic acid, and is altogether unnecessary, as its efficacy depends solely upon the presence of this acid, for which a definite formula is elsewhere given. In reference to this acid, it may be well to remark that the dilute hydrocyanic acid is now of uniform strength throughout Great Britain, and that this preparation should be henceforth exclusively employed in practice.

SUMMARY OF THE WEEK.

MEDICAL EXAMINATIONS IN THE UNIVERSITY OF EDINBURGH.

We have already commented upon the extreme absurdity of some of Mr. Syme's views on the subject of Medical education, and we now find that he has had influence enough with the Senatus Academicus of the University of Edinburgh to propose an alteration, of a most questionable character, in the mode of teaching and examining students in that institution. One very objectionable feature which already distinguishes the examinations for the Medical degree at that University is the fact that the Examiners and the Professors are the same persons, and although we do not, by any means, assert that in this case any injustice is done, yet, if the principle were generally adopted elsewhere, it is quite evident that Medical examinations would become a mere farce. Professors and teachers are, of course, liable to the weaknesses of humanity, and if the teachers of every school were to be the judges of the proficiency of their own pupils, and were to possess the power of granting or withholding licences and diplomas, it is quite obvious that such a plan must be an utter failure. Now, however, it is proposed not only that the Professors of the University of Edinburgh shall continue to exercise the power, in their corporate capacity, of granting degrees to their own alumni, but that each separate Professor shall determine by means of periodical class-examinations of his own pupils, whether the latter are competently instructed in the subject which he teaches. It is true that it is proposed to associate Assessors with the Professors in these examinations, but the scheme is altogether a bad one, and we hope that it will not be adopted, inasmuch as an example would thus be set to other and inferior institutions, and a most disastrous lowering of the whole status of the Profession must inevitably ensue.

THE LONDON COLLEGE OF PHYSICIANS AND THE GRADUS AD PARNASSUM.

We are sorry to have to repeat our accusation against the College of Physicians of dealing in false quantities. The lecturer on the Pharmacopœia, while giving very accurately the atomic numbers of the chemical compounds, is by no means equally accurate in the metrical numbers necessary to be observed in poetic rhythm. He calls lauro-cerăsus lauro-cerāsus, in defiance of Virgil, who thus writes (aptly enough, when the subject is lauro-cerasus, and the Gradus ad Parnassum) in the Second Georgic:—

"Ut *cerăsis*, ulmisque; etram *Parnassia laurus*," &c.

Truly the Parnassian laurel cannot be awarded to the College of Physicians if they go on at this rate, defying the authority of Apollo and the Muses.

A FEVER EPIDEMIC AT FESTINIOG.

An epidemic fever occurring in the village of Festiniog, in Merionethshire and the adjacent hamlets, has attracted the attention of the Medical Department of the Privy Council, and Dr. George Buchanan has been sent to the spot to inquire into the nature and causes of the disease Although the Report drawn up by Dr. Buchanan is not yet printed, the subject has been prominently noticed in the columns of the 'Times,' which represents the case as one wholly devoid of mystery. Such, however, is not exactly the fact, at least in a Medical point of view, for the particulars disclose circumstances in connection with this outbreak of fever which are at variance with the views generally entertained in the present day. It seems that Festiniog is not an unhealthy place, and for twenty years no epidemic of fever has been noticed; the air is pure, and the natural drainage is good, and there is neither general destitution nor intemperance among the population. Th sole cause of the fever, so far as it can be ascertained, i the crowded condition of the houses, which are occupied a lodgings by the slate quarriers, who have increased i number while the number of houses themselves has re mained stationary. The consequences are that the dwelling are overcrowded, and the rooms are occupied by a doubl set of tenants, those who go away to their work bein immediately replaced by those who have just left off. Tl curious and interesting points in the history of this fev in a Medical point of view are that the fever is not typh but typhoid, which has hitherto been considered as du not to overcrowding, as at Festiniog, but to some speci miasm which, in the present instance, has not been foun to exist. The fever is also contagious, although typho fever is generally considered to be non-contagious. these particulars had been recorded by any other author than that of Dr. Buchanan we might perhaps doubt th accuracy, but as it is they appear to throw a new li upon the nature of these fevers, and to show that ty and typhoid fevers are not marked by such prominen distinctive characters as is generally supposed.

THE CASE OF CANDLER *v.* PEAT.

The Medical Profession in Colchester and its neighb hood have not been remiss either in the demonstratio their sympathy for Mr. Peat, or in their determina thoroughly to sift the medico-ethical bearings of the w case. It appears that very soon after the trial, and v the costs were payable, the plaintiff became a bankr thus leaving Mr. Peat to pay expenses for his own def to the amount of 150*l.* or 160*l.* A very general and very

per feeling arose among the Medical men of the district that they ought to show their sense of the injustice of the action by uniting to raise a sum sufficient to bear Mr. Peat harmless of the costs of the trial. A meeting was accordingly held at the house of Dr. Bree, in Colchester, on the 26th ult., when it was resolved that a subscription should be commenced to defray Mr. Peat's expenses, and a committee was formed to carry out this object. Moreover, Mr. Peat has brought the subject before the Colchester Medical Society, with a view of allowing Mr. Smith, of Manningtree, an opportunity of explaining the part (if any) which he took in the transaction. An extraordinary meeting of the Society was accordingly to be held yesterday, Feb. 9, at Colchester, when the charges made by Mr. Peat, and the explanations offered by Mr. Smith, were to be taken into consideration. Mr. Smith, it will be recollected, denies (in a letter inserted in our columns of Jan. 20) any participation in the getting up of the action, and we shall rejoice to find that his explanations are satisfactory to his Medical brethren. In justice to ourselves, also, we beg it may be recollected that we have charged Mr. Smith with nothing, but we join in requesting him to explain certain matters connected with the late trial.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

MR. CRITCHETT concludes his lectures on the "Diseases of the Lachrymal Apparatus," and he now describes in detail the modern treatment of those morbid conditions of the canaliculi and the nasal duct, which in their worst and most advanced form, have been known under the term *fistula lachrymalis*. This part of ophthalmic surgery has been improved by Mr. Bowman, who has adopted a kind of proceeding analogous to that employed in the cure of stricture of the urethra, although the minuteness of the structures concerned in the lachrymal apparatus render the operation somewhat delicate, and consequently difficult. The plan consists in introducing the blade of a fine pair of scissors into the punctum, and passing it along the canaliculus as far as the caruncle, and then laying open the canaliculus. The next part of the proceeding is to pass a probe down the nasal duct, but this requires considerable care and management. The cure is eventually accomplished by passing small bougies down the duct, and the material which Mr. Critchett recommends is the stem of the sea-tangle, or *Laminaria digitata*, which, from its elasticity and its expansion under exposure to moisture, is exceedingly well adapted for the purpose. DR. EDWARD SMITH commences a series of papers entitled, "Dietary in Disease," and the first disease chosen for illustration is diabetes. As this disease is essentially characterised by wasting of fluid, sugar, urea, the chlorides, and fat, it is necessary to restore these substances to the system by means of a limited supply of fluid, and of highly nitrogenized food, and of oil. The administration of sugar itself in this disease, is neither beneficial nor injurious, it is merely useless; but starchy food should be avoided, as it is converted into sugar. The following is a summary of the diet to be adopted in diabetes, in Dr. Smith's own words.

1. *Fluids.*—To be limited by degrees daily until they shall not exceed five pounds and a half in both fluid and solid food. Of this quantity two or three pints should consist of new or skimmed milk, and one pint, or less, of tea. In the cold season and at night they should always be given when hot. Of all alcohols brandy is the best, and may be given with water only, or added to milk, or beat up with egg and milk, and given several times daily. No fluid should be given in greater quantity than half a pint at a time, and when milk is reduced in volume by cooking, the daily quantity of fluid must be made up by an additional supply of the same or other fluid.

2. *Solids.*—Dr. Prout's combination of eggs and milk (with sharps substituted for bran) is excellent. Four ounces of sharps (the inner husk of wheat) and 4 oz. of peas, beans, or lentils may be made into bread or pudding, with milk, or into omelettes with eggs and herbs. Eggs and gelatin may be given when starchy food cannot be altogether intermitted. Eggs, gelatin, cheese, gluten bread, meat, fat, and oils may be given as largely as they can be digested. The free use of salad oil should be urged, whether in the cooking of fish or flesh, or in the use of water-cress as a salad, or drunk alone, so that several ounces may, if possible, be consumed daily; but as there are in all persons preferences and dislikes in reference to particular fats, that kind—whether butter, suet, oil, or fat of meat—should be allowed which is the most agreeable. Four oz. of sharps, 3 oz. of wheaten flour, 5 oz. of peas, 1 lb. of meat, 2 oz. of cheese, 2 pints of milk, and 3 eggs, will afford more than about 13 oz. of carbon and 1 oz. of nitrogen daily.

MR. JAMES R. LANE contributes a paper on "Recto-Vesical Lithotomy," and describes a "Recto-Urethral Fistula" following that method, cured by plastic operation. The paper is suggested by the recommendation made by Dr. Marion Sims to perform lithotomy in women by vaginal incision, and in men by an incision through the rectum. With the former recommendation Mr. Lane concurs, but not with the latter. Recto-vesical lithotomy has been almost entirely abandoned in consequence of the great danger of the operation, but it was adopted by the late Mr. Lloyd, in one case which came subsequently under the notice of Mr. Lane, and in which a recto-urethral fistula had been produced. Mr. Lane denuded the edges of the fistula, and brought them together by silver wire sutures, and the ends of the sutures brought through the apertures in a narrow leaden plate. The latter and the sutures were removed eight days after the operation, and a perfect recovery was the result.

THE 'MEDICAL TIMES AND GAZETTE.'

DR. SIMPSON continues his very able, learned, and practical remarks on "Acupressure," as a portion of his "Clinical Lectures on the Diseases of Women." He maintains that acupressure is a much safer method of arresting hæmorrhage than the ligature, and he even attributes in some measure the high mortality of surgical operations to the effects of the ligature of the arteries, which proceeding tends to cause sloughing and suppuration, and the absorption of morbid matter into the system, causing pyæmia, low fever, and death. He argues that if the ligature is made of organic matter, it imbibes animal fluids which speedily decompose and become sources of irritation, while

no such danger is to be feared from the presence of metallic needles or threads which are incapable of imbibition. Dr. Simpson concludes his lecture by a tabular statement drawn up in parallel columns showing the comparative merits of the ligature and acupressure. DR. GARROD continues his "Lectures on the British Pharmacopœia," and commences by describing some of the changes of nomenclature which have been introduced. He then treats of aconite and its active principle, now called aconitia; of aloes, of which the Socotrine and Barbadoes varieties only are now retained, the Hepatic being discarded. In speaking of the salts of ammonia it is noticed that the solution of the acetate of ammonia is five times stronger than the compound of the same name in the London Pharmacopœia, a circumstance which should be carefully kept in mind by prescribers. Benzoate and phosphate of ammonia are new introductions, the former being a diuretic, and serviceable in cases where there is a tendency to phosphatic deposits, the latter being apparently useful in the treatment of some chronic cases of gout. MR. JOHN K. SPENDER communicates a paper on "Some Points in the Medicinal Treatment of Chronic Pulmonary Consumption," and he recommends a mode of treatment consisting of the administration of alkalies, especially potash and lime, of iron, especially in the form of the potassio-tartrate, of cod-liver oil, and of good diet and wine. DR. S. J. GEE relates a "Case of Unilateral Palatine Paralysis and Anæsthesia after Diphtheria. The patient was a lady, in whom, after an attack of diphtheria, the left half of the soft palate was motionless and incapable of being excited by irritation such as scratching or tickling, while the right half was in all respects normal. This state lasted for about thirty-three days, and then ceased rather suddenly.

GENERAL CORRESPONDENCE.

MERCURY IN SYPHILIS.

To the Editor of the Medical Circular.

SIR,—In Dr. Drysdale's work on "The Treatment of Syphilis, &c., without Mercury," page 16, I find this extract from Mr. J. S. Mill's "Logic." "Recovery from a disease is an event to which in *every instance* many influences must concur. Mercury may be one such influence; but from the very fact that there are many other such, it will necessarily happen that, although mercury is administered, the patient, for want of other concurring influences, will often not recover."

The want of other concurring influences conducive to recovery, so general amongst the poor, renders it anything but singular that their children die in spite of every treatment. The only remarkable circumstance is that, amidst filth and foul air, with food bad in kind, and imperfect in quantity, so many arrive at maturity.

Such reasoning, however, and such death-producing causes, Dr. Drysdale entirely passes by and endeavours to support his leading case against the use of this drug, by the expression of a mere opinion, viz., that the death of the child in question (see MEDICAL CIRCULAR, Jan. 6 and 27) was caused by the mercurial ointment which he (Dr. Drysdale) administered on the flannel band. If so, he drives me to the conclusion, either that the dose so administered was excessive, or that the case was unsuited for mercurial treatment, for it is evident that Dr. Drysdale is not conversant with, since in his writings he entirely ignores, the practice of those who give mercury only in carefully selected cases, and in these with extreme caution. Given in this way, however, prejudice alone could attribute any death to such a cause.

That success attends the anti-mercurial treatment of syphilis under the able hands of Dr. Drysdale, I have no doubt; but universal success is unattainable by any treatment, and belief in such reminds one of that of former days in the immortalizing powers of cinnamon water,

"Cur moriatur homo
Qui bibit de cinnamomo."

In Dr. Drysdale's reply to my letter (MEDICAL CIRCULAR, Jan. 6th), I am astonished to find him calling attention to the debate on Mercury in Syphilis, before the Harveian Society, Nov. 19th, and Dec. 10; for on consulting MEDICAL CIRCULAR, Dec. 2nd, and 16th, 1863, it will be found that the whole weight of evidence was decidedly against the anti-mercurialists. I am, &c.,

RICHARD S. SISSON, M.D.

Maida Vale, February 1, 1864.

MEDICAL SOCIETIES.

HARVEIAN SOCIETY, JANUARY 21.

PRESIDENT, WM. ADAMS ESQ., in the Chair.

MR. DE MERIC read a paper

ON INDURATED CHANCRE IN THE FEMALE,

in which he related three cases of infecting chancre in the female; viz., of the cervix uteri, the labium, and fourchette respectively. He was anxious to bring the cases forward as the percentage of indurated chancre in the female was small, and chancre of the cervix was rarely met with. He had, moreover, had the opportunity, in the two other cases, not only to watch the sores from the beginning, but to examine the men from whom these chancres had been taken. The sore of the cervix was of the hard glazed kind, and had seemingly been taken from a gentleman with blotches on the face, and a sound penis. The lady made a good recovery after a sufficiently prolonged mercurial course. The chancre of the labium was also derived from a gentleman labouring under secondary syphilis; but with sound organs of generation; whilst the chancre near the fourchette was taken from a gentleman affected with a chancrous erosion seated on a very large indurated base. Mr. de Méric alluded to such cases of chancre of the cervix which had been quoted by authors, and concluded by some remarks on the occasional transformation of indurated chancre into a mucous tubercle.

MR. CURGENVEN did not quite agree with the common doctrine, that syphilis was always inoculated by the *contact* of infected persons. He had seen several cases to prove the contrary. He related a case where a sailor had been for many weeks away from land before he perceived himself to be affected with an ulcer of the penis. With regard to the natural history of syphilis, when untreated by mercury, he had related two cases of severe symptoms having arisen, in the debate on Dr. Drysdale's paper, and would now add a third. A man he had recently seen had had chancres, which were treated without any mercury, and healed by external applications. He continued well for about six years, and then his health suddenly broke down. Among other symptom he was troubled by frequent emissions of seminal fluid especially in the presence of females; these left off, and h became quite impotent.

DR. DRYSDALE said he believed that indurated chancr was of very rare occurrence in the female. M. Cazenav indeed, had recently asserted that secondary symptoms i women arise in nineteen-twentieth of cases without an ulcer, but simply after discharges. As to the inoculatio of secondary symptoms, experiments by Ricord, &c., showe this to be very rare. He begged, in answer to Mr. de Méric allusion to his views, to state, that he had as high a respec for all attempts to ascertain the diagnosis, or sequence c

events, in syphilis, as in all other diseases. It was always one point gained. But it by no means followed, even if we admitted the description of events given by Ricord &c., that we should grant that the disease should be treated by such an agent as mercury. For the experience of Fricke, Desruelles, John Thompson, Syme, Hughes Bennett, &c., had shown that mercury always made the disease a thousand times worse, and that it was *in the immense majority* of cases a very mild affair, when treated with hygiene and external applications. As to secondaries, Professor Boekh had recently shown by large comparative experiments, that they occurred nearly twice as often when ulcers were treated with mercury, and the time required for treatment was nearly double. Dr. Diday, formerly a mercurialist, shows now the miseries which result from M. Ricord's six-months' course of mercury, and Cullerier, Fournier, &c., in Paris, give none in primary sores. Infantile syphilis was comparatively speaking rare—one in a hundred of out patients at the Childrens' Hospital—and it did much better without mercury than with it. Dr. Diday had shown that cases of secondary symptoms, treated by him without mercury, had been free from relapses for periods varying from four up to sixteen years.

DR. G. DE GORREQUER GRIFFITH said, you will, sir, pardon my rising to take part in this discussion, when I state that my object is to lay before the Society some interesting facts in connection with the natural history of the disease now under consideration. At the recent debate in this room upon the same subject as engages our attention to night, I advanced the fact that, while in China, I had many opportunities of seeing those bad forms of the disease usually ascribed to be the consequences of an amalgam poison, that is, the poison generated by the introduction of mercury into a syphilitic constitution; that I had carefully examined into the histories of such cases, and had been able distinctly to trace the existence of only one poison in the system, that poison being the syphilitic. In the instances to which I refer, no mercury had been at all, at any time, or in any quantities, administered, and yet the patients had flattened noses from the removal *by the syphilitic disease* of the nasal bones, and there had developed themselves in various sites of the body, nodes, caries, necrosis, rupia, ecthyma, &c.

Since my return home, I have devoted some attention to the study of the disease, as it occurs in these countries, especially to the occurrence of these so-called *mercurio-syphilitic* sequelæ, and am glad to find that the statement which I adduced in the course of the discussion upon Dr. Drysdale's paper—namely, that though they sometimes may be the results of the amalgam poison, yet they are at others *solely* dependent upon the syphilitic virus,—corroborated by Dr. Daniell in his work upon 'African Diseases,' and by the words of Mr. Erichsen, whom, upon a recent occasion, I heard say in the theatre of University College Hospital, that he had in a number of instances observed the same sequelæ as I have mentioned, in patients, who had never taken any of the mineral; also by a case which he at the time brought forward as confirmatory of his remarks. It was that of an army hospital mate, who had contracted chancre some years before, had never taken for it an atom of mercury, yet who *now* was the subject of necrosis and of caries (on account of which Mr. Erichsen had to operate), having, I believe, previously had rupia and ecthyma. I would mention another case bearing upon the same point, and which has come under my own notice; the patient is at present in the Lock Hospital. His history is as follows:—some years since, after entering the marines, he got hard chancre; this was cured by the simple plan of treatment and for two years there were no manifestations of the affection; at the end of this period the man fell into bad health, and then his body became covered with ecthymatous and rupial patches, which again, under simple treatment, and as the health was restored, totally disappeared, leaving only their cicatrices. The cause of the deterioration of health was a hard bout of drinking, immediately after which the patches had declared themselves.

Again, owing to family distress, his health broke down, and at the same time the former eruption returned. The face, neck, trunk, and limbs, have been, and some of these still are, covered with the crusts, or the cicatrices or suppurating sores of ecthyma. Another case also occurs to my memory; it was mentioned to me by Mr. Shillitoe, and inasmuch as the patient moves in the higher circles of society, his statement must be accredited.

He contracted chancre, for which he was treated without any mercury, the sore healed, and the disease seemed to have been entirely eradicated; yet, after the lapse of a long time, it manifested itself in those untoward symptoms which are accustomed to be considered as following only the mercurio-syphilitic taint—I allude to bad forms of tertiaries.

These, sir, I contend to be links in a great chain of facts, and are weighty in that they should influence us in our treatment, and guide us in the selection of remedies for the eradication of this terrible disease.

MR. BERKELEY HILL remarked that he had been informed by the Surgeon of the St. Lazare Hospital at Paris, that the cases of indurated chancre in the female did not exceed 16 per cent.

DR. CHOWNE gave an eulogium on the rigid accuracy shown by Mr. de Méric in the observation of his cases. The subject treated of was one in which society, as well as medical men, was deeply interested. With regard to the mechanism of infection, it was, he thought, often a matter of great difficulty to say what part was the infecting one, since in females the discharge was sometimes so profuse, as to make all attempts at diagnosis extremely difficult. With regard to mercury, he had been in practice for nearly fifty years, and had heard the observations of Guthrie, Rose, &c.; but he could only say with regard to that drug, that he looked upon it as the great agent to which he felt inclined to apply in all diseases, when other means proved inefficacious.

MR. DE MERIC, in reply, said, that the cases cited by Mr. Curgenven were interesting. He was, however, very strict towards his own, and would, therefore, remind Mr. Curgenven that his cases, if proved, would amount to causing a revolution in the literature of syphilis, since he had mentioned a case where a man was cured of chancre and remained without any symptoms for six years, and then the disease reappeared; a sequence not admitted by writers on the disease. We could not tell what he had been doing between these dates. Dr. Griffith's cases were less liable to adverse criticism; but even they might be taken exception to. He had not that evening intended alluding to the question of mercury in syphilis, but had merely intended to pay a passing compliment to the zeal displayed by a member in collecting evidence against its use. He thanked Dr. Chowne for his good opinion of his method of collecting materials for diagnosis. One suggestion thrown out by that gentleman was very valuable, viz., that it was often very difficult to ascertain the infecting focus, in the case of profuse discharges in the female.

The PRESIDENT announced that, on February 4, a paper would be read by Wm. Adams, Esq., F.R.C.S., on "Fracture of the Patella."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 26TH, 1864.

MR. FERGUSSON, VICE-PRESIDENT, in the Chair.

Dr. S. O. HABERSHON related some

CLINICAL OBSERVATIONS ILLUSTRATING THE EFFECTS OF IMPLICATION OF THE PNEUMOGASTRIC NERVE IN ANEURISMAL TUMOURS AND MORBID GROWTHS.

After referring to the complex distribution of the pneumogastric nerve, and to the important symptoms of disease produced by the implication of its branches, the author proceeded to describe several cases of thoracic aneurism in which the branches of the recurrent laryngeal nerve, or the trunk of the pneumogastric, were involved.

The first case was that of a man, aged thirty-nine, who had been engaged in laborious work at Chatham and Woolwich dockyards. Two months before death he began to

suffer from hoarseness, and the laryngeal symptoms were more marked than any other. There were paroxysms of urgent dyspnœa, and slight dysphagia. Five days before death hæmorrhage from rupture into the trachea commenced; and on the morning of his death the bleeding suddenly became profuse, and was quickly fatal. Dilatation of the aorta, double aneurism of the arteria innominata, and perforation into the trachea, were found. There was pressure upon the commencement of the recurrent nerve, and commencing degeneration of the muscular fibre of the laryngeal muscles on the same side. As to the physical signs, dulness and double bruit were produced immediately over the first bone of the sternum, but there was no bruit over the aortic valves. No pain had been complained of. The valve of the laryngoscope had been shown in demonstrating that no disease of the larynx existed, slight œdema of the mucous membrane only being present.

The second case was that of a sailor, aged thirty-five, who had apoplexy, with aphonia and symptoms resembling phthisis; aneurism was, however, suspected. The recurrent and the pneumogastric nerves were both compressed; the muscles of the larynx were on one side pale and wasted, and the lung on the same side was in a state of asthenic pneumonia. The thoracic duct had also apparently been compressed.

In the third instance recorded, the symptoms of cardiac disease obscured those of aneurism. There had been pericarditis and endocarditis, and fibroid degeneration of the muscular fibre of the left ventricle existed. The patient was a groom, aged forty-five, and two months before death symptoms of catarrh and bronchitis came on; the heart's action was irregular and tumultuous; the pulse very feeble, but without bruit. Afterwards a triple sound was produced below the nipple, and with renewed bronchitis there were signs of pleuro-pneumonia of the lower lobe of the right lung. No pain and no dysphagia were complained of, but paroxysms of urgent dyspnœa, with extreme faintness; in one of these attacks he died. In addition to the degeneration of the heart, an aneurism was found at the commencement of the transverse arch; and the pneumogastric, after giving off its recurrent branch, passed directly over the sac, and the compression of this nerve had determined the pneumonic consolidation of the lower lobes of the right lung.

In the fourth case, the recurrent laryngeal nerve was compressed, and had produced paroxysms of urgent dyspnœa, but the dyspnœa was in great measure due to direct pressure upon the trachea. There had been feebleness of the voice, with dysphagia. Pain was of an agonising character, but also paroxysmal, and it was apparently due to direct pressure on the nerves. The aneurism of the aorta was situated immediately beneath the subclavian, and had ultimately perforated the trachea; but rapid effusion of blood had been prevented by layers of fibrin, and it was probable that the first oozing of blood took place nine months before death. No bruit had been produced, but a ringing second sound; the heart was healthy.

The author stated that pressure on the pneumogastric nerve and its branches by aneurismal tumours in the chest led—first, to paroxysmal and spasmodic contraction of the muscles of the larynx; secondly, to diminish muscular power, and to paralysis and wasting of the laryngeal muscles; and thirdly, to pulmonary congestion and consolidation;—but that gastric symptoms, such as were found in peripheral pulmonary irritation of incipient phthisis, were not observed in thoracic aneurism. The effect of changed nervous supply of the œsophagus was briefly referred to; spasmodic contraction, and possibly also ulceration, taking place without direct pressure; the author stating that spasmodic contraction from this cause aggravated the effects of the direct pressure of tumours generally. It was likewise mentioned that occasionally no dysphagia existed, because the whole of the œsophagus opposed to the tumour was pushed aside *en masse*.

In conclusion, the author detailed an instance of disease affecting the supra-renal capsule, with bronzed skin; and exhibited a drawing from his dissection of a branch of the neumogastric to the capsule. The irritability of the stomach often present in these cases was referred to this connection. A dissection showing the larger branches of the semi-lunar ganglia, and the manner in which some of these branches were involved in the diseased capsules, was also exhibited.

Dr. JOHN HARLEY reported a case of

HÆMATURIA OF THE CAPE OF GOOD HOPE.

In the beginning of October last, a gentleman, resident in the Cape, consulted the author about a slight hæmaturia which he had had for some years. After micturition a little blood, never exceeding a teaspoonful, or some dark "veins," appeared with the last half ounce of urine. The urine itself was never bloody. Sometimes the "veins" would block up the urethra, and cause obstruction for a few minutes. He had an occasional twinge of smart pain in the loins. These were all the symptoms which ever appeared in connection with the urinary apparatus. He said great numbers of people of both sexes were affected in precisely the same way in certain parts of the Cape. While awaiting a sample of his urine, Dr. Harley made inquiries amongst his Cape friends and acquaintances, and as the result corroborated his patient's statements, he was now satisfied of the existence of endemic hæmaturia in Uitenhage and Port Elizabeth, and it remained for him to ascertain the cause. In the various samples of urine sent to him by his patient, he invariably detected the eggs of an entozoon, and in one specimen he had the good fortune to discover the perfect embryo after its escape from the eggshell, under the form of a minute ciliated animalcula. From its anatomical characters and developmental changes he was led to refer the parasite to the Trematode class of worms, and to the family Distomum. Of the five species of this genus which inhabit man, it had no relation with three. Distomum heterophyes presented some points of resemblance—viz., in the size and conformation of the alimentary canal, if he (Dr. Harley) might be allowed to compare it with an organ he met with in one sample of his own, and which he supposed to be the intestinal canal of the adult parasite. But the animal which it seemed to most nearly resemble in the outward form of the eggs as well as in the symptoms of the disease it produces, was the Distomum hæmatobium. This parasite, according to Bilharz and Griesinger, was very common in Egypt, and inhabited all parts of the urinary apparatus. But since the parts he had described differed in several respects from the corresponding parts of the hæmatobium, and since, from want of recorded information respecting the corresponding parts of D. heterophyes, he could not compare them with these, he was obliged to comprehend them under a new species, which he would call D. capense. Having finished his observations of this case, he was strongly persuaded that the hæmaturia of the Cape was due to the parasite, the early stage of whose development he had been able to observe; but still, as its presence in a single case might be nothing more than a coincidence, he felt that more extended observations were needed to prove that this was the constant cause of the local disease in question. With singular good fortune he had the pleasure of an introduction to Dr. Dunstroville, surgeon of the Port Elizabeth Infirmary, and who, having practised for twenty-seven years in the Cape of Good Hope—which was one of the two places in which he (Dr. Harley) found the hæmaturia to be endemic,—was quite familiar with the disease, the cause of which, however, from want of leisure and means of observation, had never been ascertained. Dr. Dunstroville's two sons, in common with many other young men, suffered from the disease, but considered themselves to be now free from it. At the author's request Dr. Dunstroville kindly supplied him with samples of the urine, and he (Dr. Harley) was at once enabled to demonstrate to Dr. Dunstroville the existence of the characteristic eggs of the parasite in question in the secretion from him. Having thus demonstrated the existence of the same parasite in three individuals suffering or having suffered from the hæmaturia endemic in some parts of the Cape, Dr. Harley concluded that the animal was the constant cause of the disease.

Dr. SYMES THOMPSON observed that the disease described by Dr. Harley as endemic at the Cape must be either

in its occurrence or very limited in its distribution. He had received communications from three medical practitioners who had practised for several years in South Africa, and had not met with idiopathic hæmaturia, either at Port Elizabeth, or in the neighbourhood of Uitenhage. Dr. Johnston (Surgeon to the 85th L. I.) had seen many cases of hæmaturia in Natal, occurring in children between the ages of six and fifteen, more commonly in boys than girls, which he had regarded as dependent on congestion of the genito-urinary mucus membrane, arising from ascarides, tape-worm, or depraved secretions. He had found these cases very amenable to treatment directed to the removal of the condition referred to, with the subsequent administration of turpentine, matico, or the sesquichloride of iron. Dr. Thompson added to this testimony that of a non-medical observer, the Bishop of Natal, whose sympathies are, perhaps, as much scientific as clerical, who had not, in his intercourse with medical practitioners in the colony, heard the disease mentioned as endemic in any part of his diocese. With regard to the question whether the fluke described was the same as that occurring in Egypt, though zoologically almost identical, the Distoma capense (so called by Dr. Harley) seemed far less hurtful in its effects on the human constitution than the Distoma hæmatobium. The first-named entozoon was, perhaps, a variety of the same species. The speaker suggested that the principal medical officer of the Cape be requested to investigate the whole subject, and draw up a report, to be presented to the Royal Medical and Chirurgical Society at a future meeting.

Dr. COBBOLD remarked that no person who had previously familiarised himself with the appearances presented by the eggs of the various distomes could doubt for a moment that Dr. John Harley's illustrations represented the ova of the so-called Distoma hæmatobium. In short, the symptoms, pathological products, eggs, and embryos described by Dr. Harley, all tended to show that this hæmaturia of the Cape was identical with the well-known Egyptian malady. Dr. Harley's discovery was, however, a most important one in relation to the geographical distribution and prevalence of entozootic disease; for the author had now demonstrated in a most satisfactory and able manner, that the helminthiasis in question was not confined to Egypt, as had hitherto been supposed, but was more or less prevalent in Southern Africa and in the Mauritius. Speaking zoologically, this parasite was not a true distome, as it represented the type of a distinct genus, to which Diesing, of Vienna, gave the name of Gynæcophorus; Weinland, of Frankfort, had called Schistosoma; Moquin-Tandon had denominated Tnecosoma; and himself had previously entitled Bilharzia, after the name of the original discoverer, Dr. Bilharz, of Cairo. He (Dr. Cobbold) had discovered this so-called Distoma hæmatobium in the portal blood of an African monkey (Cercopithecus fuliginosus) six months before Diesing had communicated his paper to the Vienna Academy, and, therefore, he hoped Dr. Harley (in concert with Weinland and others) would retain the generic name Bilharzia, which had the priority. At all events, this was not a new species of fluke, and, therefore, the name Distoma capense could not stand. But Dr. Harley's discovery was none the less important on that account. It was quite clear to him (Dr. Cobbold) that our fellow-men at the Cape, in the Mauritius, on the banks of the Nile—and also, if you please, our friends, the monkeys—obtained this parasite by swallowing the "intermediate bearers" of the Bilharzia. These "bearers" or "hosts" were small mollusks or aquatic animals, inhabiting the African rivers. They contained the higher larval states of this parasite, the larvæ being introduced into the human body by drinking the African waters unfiltered.

Dr. DUNSTROVILLE said that he had given Dr. Harley all the information he possessed on the subject. In reference to what Dr. Symes Thompson had said, he stated that the disease never attacks adults. There was no doubt that the water had to do with the disease, but how, it was difficult to explain. He (Dr. Dunstroville) intended, by the help of his friends, fully to investigate the disease. He remarked that disease was uncommon, and he had only seen two cases.

Dr. LEARED said, in reference to the observation of Dr. Cobbold on the possibility of preventing the occurrence of parasites in the human body, that his proposal for the prevention of the fatal cystic disease of Iceland, by simultaneously treating all the dogs in the island for worms, had been very favourably received. The paper had been translated into Icelandic, and published in an Icelandic newspaper. Dr. Leared had also communicated with the late Baron Eschricht, of Copenhagen; the result was, that Dr. Krabbe had been sent to Iceland last summer for the purpose of ascertaining whether the sheep-dogs of the country are really infested with the Tænia echinococcus, the mature form of the cystic worm which infests the bodies of men. With this view one hundred dogs had been killed, and their intestines examined. The worm was found in about one-fourth of the number. What further steps the Danish Goverment intended to take Dr. Leared was unable to say, but he still felt confidence in the plan he had proposed.

Dr. HARLEY said, in reply to several points alluded to by those who had taken part in the discussion, that since there could be no doubt the parasite in question belonged to the genus Distomum or Gynæcophorus, the determination of the exact species was a matter of secondary importance. He had referred it to a new species, because, after careful comparison with Griesinger's figures and description, and Leuckart's review of them in his recently published work, he could hardly refer the cilated embryo he had described to Gynæcophorus hæmatobium. On the other hand, the resemblances were so close and so many that it was probable they were identical; but from a bare comparison with the figures, he could not justly infer that they were actually so. He called attention to the fact that, although the symptoms of the hæmaturia disappeared after a time, the parasite still remained in the system as actively generating its kind as ever. Stone, it had been observed, was not at all of common occurrence in the locality in which the hæmaturia prevailed, but he would particularly draw attention to the fact that gravel was very prevalent. He had found that a highly saline condition of the urine accompanied the discharge of ova; and that the fine crystalline deposits very soon incrusted the ova. He had been particularly careful to satisfy himself that ova formed the nuclei of several renal calculi that had been submitted to him for examination by one of the patients suffering from the disease.

JUNIOR MEDICAL SOCIETY OF LONDON.

Abstract of Paper read before the above Society, at King's College, on January 19th, 1864, by MR. R. C. POWLES.

The author began by showing that the conditions under which pus could gain admittance into the blood were at least very exceptional, and that if pus did get into the blood, the effects produced there would be of a very different character from that class of symptoms ordinarily described under the name of pyæmia.

He showed that the formation of pus takes place as the result of a particular dyscrasia, that a purulent dyscrasia ought to be recognised as well as a cancerous one, for that in both, as the result of altered or impaired nutrition the nuclear matter of a particular structure takes on a new developmental direction. If a case of pyæmia, in the strict sense of the word, were met with, the course of events would be exactly parallel to those which take place in the rare cases wherein secondary and distant deposits of cancer have owed their origin to a transference of cancer cells by the way of the veins.

The pus corpuscles would be mechanically arrested in the nearest capillary plexus, and there would continue to grow, at length forming small tumours.

The theory that injection of pus into the blood produced peculiar effects, such as the coagulation of that fluid, as supported by Mr. Lee's experiments, or symptoms similar to those produced by a blood-poison, as Gasbard had met

with in his experiments, had been refuted, at least the striking experiments of Professor Hughes Bennett had shown that such effects were not of necessity produced.

Again, there was another point from which the whole subject might be viewed; the discoveries of Bennett and Virchow of the leucocythemic and leucocytotic conditions had, to quote the words of the Berlin Physiologist, amounted to a refutation of a morphological pyæmia.

The question yet remained—what is the true pathology of pyæmia? and Virchow's researches have rendered a definite and intelligible answer to this question possible.

The formation of multiple abscesses has two distinct causes, the one mechanical, in which a transference of embolia took place; the other, dynamical, in which, owing to the introduction of some morbid matters into the blood, and a consequent general contamination, a mal-nutrition followed, resulting in the formation of such aberrant forms as pus corpuscles.

The important question—why thrombosis occurred, and what was the starting point of the formation of a thrombus?—was touched upon, and the experiments of Professor Lister were mentioned as proving that those of Richardson were of too partial a nature for the support of his theory, and also as giving some sort of explanation of the formation of a thrombus.

It would thus appear that the disease, so-called pyæmia, must be referred to two diseased conditions—viz., embolism and ichoræmia, which, however, frequently co-exist, and either of which may give rise to the other.

With reference to the place of these affections in the whole category of diseases, the author explained the class which Virchow had framed, and which he called metastatical dyscrasiæ.

He then mentioned the principal diseases in which embolism and ichoræmia were met with, and concluded with some remarks upon the treatment.

Births, Marriages, and Deaths.

BIRTHS.

BATE.—On the 23rd ult., at Albion terrace, Guernsey, the wife of H. Bate, M.R.C.S.E., of a son.

CAMERON.—On the 29th ult., at Nottingham place, the wife of Dr. Cameron, Deputy-Inspector-General of Hospitals Army, of a daughter.

DILL.—On the 21st ult. at Regency square, Brighton, the wife of Dr. Dill, of a daughter.

HARVEY.—On the 26th ult., at Hoe place House, Plymouth, the wife of Frederick Harvey, M.R.C.S.E., Staff Surgeon, R.N., of a daughter.

JOHNSON.—On the 29th ult., at Regency square, Brighton, the wife of A. A. W. Johnson, F.R.C.S.E., of a daughter.

LE GROS CLARK.—On the 26th ult., the wife of F. Le Gros Clark, F.R.C.S.E., of St. Thomas's street, Southwark, and Lee, Kent, of a son.

MILLAR.—On the 26th ult., at Cairnbank House, Brechin, the wife of Dr. S. S. Millar, of a son.

WALKER.—On the 1st inst., the wife of James Walker, M.D., of North Frodingham, Driffield, of a son.

MARRIAGES.

BROWN—DEWAR.—On the 28th ult., at Cross hill, Cathcart, W. Brown, M.D., of Glasgow, to Margaret, daughter of the late W. Dewar, Esq., of Glasgow.

SOUTHEY—THORNTON.—On the 28th ult., at Holy Trinity Church, Clapham, R. Southey, B.M., to Frances Marianna, daughter of the late Rev. W. Thornton, Rector of Llanwarne, Ross.

DEATHS.

CLIFFORD.—On the 28th ult., at Tivoli Villa, Cheltenham, H. W. Clifford, M.R.C.S., aged 28.

HARVEY.—On the 24th ult., at San Remo, Italy, E. R. Harvey, M.D., of Clarges street, Piccadilly, aged 32.

HONEYWOOD.—On the 20th ult., J. Honeywood, M.R.C.S.E., of Blackfriars road, aged 45.

NICOLL.—On the 31st ult., at Caistor, Lincolnshire, W. Nicoll, Surgeon, formerly of The Hyde Hendon, Middlesex, aged 60.

TURNER.—On the 5th ult., at Newcastle-under-Lyne, Samuel M. Turner, F.R.C.S., Surgeon-Extr. to the North Staffordshire Infirmary, aged 45.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 28th ult.:—James Edmond Anthonisz, L.S.A., Ceylon; Charles John Bennett, Buxton, Derbyshire; Alfred John Cockerton, Islington; William Grafton Curgenven, M.D. Plymouth; Edward William Bennett Garlike, Tulse hill; Frederick King Green, Stoke Newington; Frederic Charles Griffith Griffin, Weymouth; John Petch Hewby, Ripon, Yorkshire; Frederick Samuel Hope, Kerby-Fleetham, Yorkshire; Hermann Johnston Jones, M.D., Upper Clapton; Joseph Langhorn, Savile row; Caleb Law, Australia; Henry Plater Long, Barham, Canterbury; William M'Connell, Lisburn Ireland; Edwin B. Pearson, Yeavele near Ashbourne, Derbyshire; William Cecil Penn, Edwardes square, Kensington; Frederick Philpot, L.F.I. & S. Glas., Chelsea; William Skinner, Sheffield; George White, Dalston.

At the same meeting of the Court Mr. Josiah Frederick Kynsey, L.R.C.P.I., passed his examination for Naval Surgeon. This gentleman had previously been admitted Member of the College, his diploma bearing date July 19 1859.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise, on the 28th ult. Richard Orlando Arnold, Charing cross Hospital; John Quick Costin, Kimbolton, Hants; Richard William Day, Colnbrook, Bucks; Peter Charles Duncan, Great Marborough street; Thomas Langston Hulme, Manchester; James More, Rothwell, Northamptonshire.

The following gentleman also on the same day passed his first examination:—David Martin Williams, Charing cross Hospital.

The following gentlemen passed their preliminary examination in Arts, and received certificates of proficiency in general, on the 29th and 30th ult.:—E. G. Archer, Feltwell near Brandon; R. Atkinson, Coniston, Waterhead; J. Bennett, Bury, Lancashire; W. J. Bennett, Dorchester; F. M. C. Beechey, Norfolk square; G. Bland, Stourbridge; J. H. Castle, Euston square; Clifford Crew, Ross place, Guernsey; D. S. Costerton, Lucas place, Commercial road; R. H. Coombs, Rydon crescent, Islington; F. P. Day, Birmingham; F. J. Glencross, Devonport; S. Gries, Leeds; C. V. Helsdon, Frances street, Torrington sq.; J. A. Lea, Congleton; G. J. Moxon, Brigg, Lincolnshire; S. Morrison, Westbourne park terrace; J. Massing, Green street, Bethnal Green; H. Norton, Westbrook grove, West; E. M. Owens, Sutton, Surrey; G. F. Wallingford, Berks; W. Powell, Cheltenham: O. R. Tankerd, Langport, Somerset; J. J. Swindell, Whetston M. Sculthorpe, Bedsy, Worcestershire; W. R. T. Penzance.

CAMBRIDGE UNIVERSITY.—At a Congregation held the Senate on the 30th ultimo, the degree of B.A. was ferred on J. Theophilus Beck, M.R.C.S. and L.S.A., and Thompson Dickson, M.R.C.S.

SIR WILLIAM WILDE.—The Lord Lieutenant has ferred the well deserved honour of knighthood on W Robert Wills Wilde, Surgeon Oculist in Ireland Majesty, and Assistant Census Commissioner. Sir W

has many high claims to that distinction. His labours in Ophthalmology long since raised him to a high position in that department of surgery, and his devotion to the elaboration of the vital statistics of Ireland has enabled him to render great public service in this important matter. Sir William Wilde has taken part in the compilation of three successive censuses for Ireland, and is known also by his erudite antiquarian studies, which have won for him a considerable reputation as an accomplished archæologist. We congratulate the Irish profession on the honour bestowed on one of its most distinguished representatives.

DONCASTER DISPENSARY.—Several meetings have recently been held at Doncaster, attended by the principal inhabitants, to consider the propriety of founding an Infirmary in that place. There is every probability that the proposed institution will be established. On Friday last, a deputation from the Infirmary Committee attended a special meeting of the Governors of the Dispensary, and it was unanimously agreed that the site chosen for the Infirmary would be equally eligible for the purposes of the Dispensary, the amalgamation of the two institutions being considered desirable.

ISOLATION OF FEVER WARDS IN HOSPITALS.—Dr. R. D. Thomson, in his report on the health of Marylebone for December, has the following remarks on this subject:—"From the total want of sufficient means of isolating epidemic and contagious diseases in the public hospitals, and from the increasing density of the population of the metropolis, the local authorities must in future make up their minds to provide for a certain number of sick during the prevalence of infectious zymotic disease. And that the larger and more wealthy hospitals will see fit to provide distinct isolated wards for contagious diseases, as is universally the case in country infirmaries. If this desideratum be not supplied, these institutions will in a good degree be superseded by parish infirmaries and dispensaries."

PROFESSIONAL CHANGES IN DUBLIN.—The unexpected deaths of Mr. Smyly and Dr. Jonathan Osborne have led to many changes and some speculation in Dublin. The most important, however, of the appointments which have become vacant will be filled up, we believe, without any very serious contest. The election for a Vice-President of the College of Surgeons, *vice* Mr. Smyly, has been advertised to take place on next Thursday, and Dr. Jacob, the Professor of Anatomy and Physiology in the College, is we believe, likely to succeed to the office. Then the Surgeoncy to the Meath Hospital is, we understand, on the best authority, to be filled up by the election of the son of the senior Physician, the young gentleman being at present studying on the Continent. By the death of Mr. Smyly, Dr. George H. Porter, one of the Examiners in the College of Surgeons, becomes Senior Surgeon at the Hospital, and thereupon has resigned his office to the South City Dispensary, and a contested contest is likely to ensue. The principal candidates, out of thirty-five as yet in the field, as far as we know, are, Dr. Coulton, for some years Apothecary to the Dispensary; Dr. C. F. Moor, late Senior Surgeon to the Meath Hospital, near Tynan; Dr. Grimshaw, the son of the well-known Dental Surgeon; and Dr. Shortt, a young gentleman of about five years' standing in the Profession. By Dr. Osborne's demise the Professorship of Materia Medica in Trinity College becomes vacant, and we understand that Dr. Aquilla Smith, the Vice-President of the College of Physicians, and its representative on the Medical Council, will in all probability be appointed. We shall probably in our next be able to give more certain information.—'Dublin Medical Press.'

SCHOLARSHIPS IN NATURAL SCIENCE IN CAMBRIDGE.—Two Scholarships, each 40*l.* per annum, tenable for three years at least, are announced to be given for Natural Science at Sidney Sussex College in October next. The subjects of examination are Electricity, Chemistry, Geology, and Anatomy. The scholarships are open to all the world. The successful candidates must enter at the College and reside. Further information may be obtained from the Rev. J. C. W. Ellis, tutor of the College.

BITE OF A VIPER, SECONDARY SYMPTOMS RECURRING PERIODICALLY AT DISTANT INTERVALS.—In 1855, Mr. Léon Soubeyran in his thesis on vipers and venemous bites, recorded the singular case of a man who having been bitten by a reptile of this kind six years previously, experienced annually for a month, from the date corresponding to that on which the wound was inflicted, severe pain in the injured arm. Mr. George Villers, of the Calvados, had also noted a periodically returning swelling in dogs, several years after bites of this description. The first case was therefore not a solitary instance, and was merely invested with exceptional interest. This extraordinary circumstance would seem however to be confirmed by further observations and in its number of November 6th, the 'Gazette Hebdomadaire,' relates a fresh case, communicated by Dr. Demeunat, of Tournan. A woman, aged sixty-five, was bitten by a viper at the age of twenty-six, and for a period of thirty-nine years every spring, on the 28th of May, an eruption of large vesicular bullæ has appeared on the forearm, attended with much itching, but no other disturbance of health.—'Journal of Practical Medicine and Surgery.'

TENDERNESS BENEATH THE STERNUM, A SYMPTOM OF SYPHILIS.—In addition to exostosis of the mesial portion of the palate, which Mr. Chassaignac considers as indicative of the presence of syphilis, we may mention another symptom frequently met with according to Mr. Ricord in secondary disease; and which, in Mr. Brodrick's opinion, is so common as to present a pathognomonic character. Mr. Brodrick has observed it in a large number of cases at Madras, and the 'Dublin Medical Press,' in an article devoted to the subject, remarks that this gentleman attaches so much importance to the presence of this sign, that whenever he detects in the lower third of the sternum a spot unusually tender on pressure, he does not hesitate, if no spontaneous pain has preceded, to pronounce the case one of syphilis, and accordingly to exhibit iodide of potassium.—'Ibid.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, FEB. 10.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Dr. Garrod: "The British Pharmacopœia; its Construction, its Comparison with the London Pharmacopœia, and the Value of its New Remedies in the Treatment of Disease."

THURSDAY, FEB. 11.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Tyndall, "On Experimental Optics," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

FRIDAY, FEB. 12.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Gulstonian Lectures: Dr. Markham, "On the Uses of Bloodletting in Disease;" Royal Institution, 8 p.m.—Professor Franklyn, "On the Synthesis of Organic Bodies."

SATURDAY, FEB. 13.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, FEB. 15.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, FEB. 16.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Social Science Review. No. 2. New Series.
The Medical Mirror. No. 2.
Canada Lancet. No. XI.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

Mr. W. B. MURRAY.—The abstract has been received, and will be inserted.

Dr. SISSON'S letter is inserted.

THE BROMIDE OF AMMONIUM IN AMENORRHŒA.

To the Editor of the Medical Circular.

SIR,—Would you kindly allow me through the medium of your columns to ask the members of our Profession, if they have in any instances of the above-named affection found the Bromide of Ammonium useful? Some little time since I demonstrated this drug to be an emmenagogue and that too of powerful action. Drs. Locock and Dewees have recorded the good effects of the ergot in amenorrhœa, and their statements have received the corroboration of Nauche, Pauly, and Roche. Now we know, that this latter drug most powerfully checks uterine hæmorrhages—that opium will behave itself, at one time, as a stimulant, at another, as a paralysing agent, and that lead may in certain quantities prevent, while in larger doses, it will produce abortion. Of many other medicines, which act thus *oppositely* in *different* doses, I might cite numerous examples, but I content myself with the references which I have made. Dr. Churchill in his new work on 'Diseases of Women,' speaking of the ergot, says: "that ergot of rye will originate and augment uterine contraction is known to all, and also that it will control uterine discharges therefrom; but upon what principle it could be supposed to possess the opposite power,—viz., that of exciting or increasing the menstrual secretion, I do not know."

I lately published a paper in your journal, in which I called attention to the benefit derivable from the use of the Bromide not only in Amenorrhea and Dysmenorrhea, but likewise in Menorrhagia and Metrorrhagia.

I seek not to offer an explanation of the *modus operandi* in these diametrically opposite conditions.

Lock Hospital. G. DE GORREQUER GRIFFITH.

Dr. H. is thanked for his communication, which, however arrived too late for insertion last week.

INQUIRER.—The term *paresis* has been lately employed to express the condition which has hitherto been known under the name of general paralysis. The word is a Greek one, παρεσις, and signifies relaxation. The e of course is short.

A CHEMIST.—No time has yet been fixed for the appearance of the six-shilling edition of the British Pharmacopœia, of which it is said fifty-thousand copies are being struck off at the higher price of ten shillings and sixpence.

Dr. M.—We cannot take any notice of the subject, until the investigation is concluded.

DOCTOR OR NO DOCTOR.—The question is not likely to be settled soon, as whichever way the judgment is given, the defeated party will appeal.

Dr. D.—The Clinical Report is exceedingly well drawn up, and we shall be happy to receive and to insert others of a similar nature.

A SCOTCH STUDENT.—We have already expressed our views on Mr. Syme's pamphlet, but we shall follow up the subject as occasions may present themselves.

A. B. C.—The bye-law in question applies to the Fellows, but not to the Members or Licentiates. The legal point is quite decided, but the jury may take what view they please as to the amount to be awarded.

Mr. C.—The conduct of Mr. S. appears to have been unprofessional, and ought to be referred to the decision of a Medical tribunal.

Dr. C., EDINBURGH.—The proofs had not returned in time for the insertion of the Report this week.

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Baréges, Harrogate, and other Baths, constantly ready, or prepared to order.

Highly esteemed, and mainly supported now for upwards of forty years by the goodwill and recommendation of the leading practitioners of London and the United Kingdom; as an additional very powerful, and agreeable remedy in tedious chronic disease. Ample evidence can be given of their efficacy in mental and nervous disorders, incipient paralysis, internal congestions, and especially in obstinate cutaneous, syphilitic, rheumatic, and gouty affections, as well as in glandular, hepatic, and other visceral enlargements and obstructions, where internal medicines are inadmissible or have altogether failed.

Especial attention having been latterly directed to the high promise of the HOT-AIR BATH in pulmonary, and even confirmed phthisical disease, a great object will be to carry out this treatment judiciously and effectually, and to assist, as far as possible, any object or purpose the preseriber may have in view.

Medical Gentlemen, presenting their cards, are free to a personal use of the Baths at any time when at libetry, at no other charge than a small optional fee to the attendants. Imitations having arisen, be particular in the address.

Emperor Life and Fire Assurance

SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

Hedges & Butler, Wine Merchants,

&c., recommend and GUARANTEE the following WINES;

Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s. and 30s.	per dozen.
Good Hock	30s. ,, 36s.	,,
Sparkling Epernay Champagne, 36s., 42s.	,, 48s.	,,
Good Dinner Sherry	24s. ,, 30s.	,,
Port ..... 24s., 30s.	,, 36s.	,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820 at	120s	per dozen.
Vintage 1834	,, 108s.	,,
Vintage 1840	,, 84s.	,,
Vintage 1847	,, 72s.	,,

all of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s.; superior Sherry, 36s., 42s 48s.,: Clarets of choice growths. 36s., 42s., 48s., 60s., 72s., 84s.: Hoch heimer, Marcobrunner, Rudesheimer, Steinberg, Liebraumilch, 60s. Johannesberger and Steinberger, 72s., 84s., to 120s.; Brauneb rger, Grur hausen, and Scharzberg, 48s, to 84s.; sparkling Mosell, 48s., 60s., 66s. 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontig nac, Vermuth, Constantia, Lachrymæ Christi. Imperial Tokay, and othe rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; ver choice Cognac, vintage 1805 (which gained the first class gold medal at th Paris Exhibition of 1855), 144s. per dozen. Foreign Liquers of ever description. On receipt of a post-office order, or reference, any quantit will be forwarded immediately by

HEDGES & BUTLER,

London, 155 Regent street, W.; and 30 King's road, Brighton.

(ORIGINALLY ESTABLISHED 1667.)

Kinahan's LL Whisky v. Cogna

BRANDY.

This celebrated Old IRISH WHISKY rivals the finest French bran It is pure, mild, mellow, delicious, andvery wholesome. Sold in bottl 3s. 8d. each, at most of the respectable retail houses in London; by t appointed agents in the principal towns in England; or, wholesale, 8 Great Windmill street, Haymarket.—Observe the Red seal, pink lat and cork branded "Kinahan's LL Whisky."

Fine Old Port, Twelve Years i

Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clar 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pi 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Qua 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

A Cup of Coffee in One Minut

—DUNN'S ESSENCE of COFFEE, 1s. and 2s. per bottle. Ma had everywhere. Warranted to keep good in any climate.

The Medical Circular.

HOSPITAL REPORTS.

EDINBURGH ROYAL INFIRMARY.

CLINICAL WARDS. CASE UNDER THE CARE OF PROFESSOR LAYCOCK, WITH CLINICAL OBSERVATIONS ON CARDIAC NEUROSES.

(Reported by FRANCIS C. ROPES, M.A., M.D., Boston, and Mr. HERBERT TAYLOR, Clinical Clerks.)

Suspected Thoracic Aneurism, Substernal Pain, Neuralgia of both Upper Extremities, chiefly on left side, "Pin-point" Pupils. Sudden Death from Angina Pectoris. Sectio Cadaveris, Fatty Heart, Atheroma of Aorta and Coronary Arteries.

S. Matchbank, **æt. 33,** married, residing at Hawick, was admitted on Nov. 21, 1863, to Clinical Ward No. 1, under the care of Dr. Laycock.

History.—Is a stocking-maker by trade. Enjoyed good health up to the month of September last when he had a fit. This occurred as he was entering his house, he first felt weakness in the legs, and then fell unconscious to the ground. He was taken to bed and seen shortly afterwards by a medical man who bled him at the arm.* Under this treatment he recovered consciousness, and feeling able for work the next day, he returned to his occupation. Since this time, he has complained of substernal pain and shooting pains down both arms, aggravated by exertion, but not constantly present.

SYMPTOMS ON ADMISSION.

Integumentary System.—Complexion sallow, hair black, skin over the abdomen pigmented, and almost of bronze colour. There is a line of dilated capillaries in the cardiac region, constituting the so-called præcordial vascularity.

Circulatory System.—Pulse 78, small vol., regular, feeble. On auscultation, a rough diastolic murmur is audible, loudest at the base of the heart and propagated down the sternum; no increase of cardiac dullness on percussion.

Respiratory System.—Natural.

Digestive System.—Tongue clean, appetite good, bowels regular.

Genito-Urinary System.—Urine, pale yellow colour, sp. gr. 1·020, acid reaction, depositing octohedral crystals of oxalate of lime with mucus.

Nervous System.—He complains of general weakness, of pain in the mid-sternal region, shooting especially into the left axilla and down the left arm as far as the elbow. The pain is sometimes felt in the right shoulder and arm, and is aggravated on using the arms actively. The pupils are contracted to two small points, and do not obey the stimulus of light.

He was ordered good diet, and a placebo in the meantime.

* This fact was not elicited till after the patient's death when the friends afforded the information.

Nov. 27.—In the same condition. The murmur at the base of the heart is not so distinct as when first observed; ordered three grains of iodide of potassium in infusion of quassia three times a day.

Dec. 2.—Thorax carefully examined at the visit to-day. No increase of cardiac dullness is detectible on percussion; the murmur at the base is not heard: patient complains of pain at mid-sternum stretching to left axilla, down the left arm to the inner side of the elbow. Urine is free, contains no oxalates and no albumen, sp. gr. 1·025. Pupils continue firmly contracted and unaffected by light.

Dec. 3.—With a view to ascertain whether the cardiac murmur heard on admission could be reproduced after exertion, the Resident-Physician ordered the patient to carry a pail for some distance, and to return to be auscultated. He was in the habit of assisting the nurses to carry the food from the kitchens up stairs to his ward, and thus frequently carried moderate weights without any inconvenience. On this occasion, in his anxiety to assist in elucidating the nature of his complaint, he had doubtless made some unwonted exertion, for on returning with the pail he put his hand on his chest and told the nurse "the doctor would now find out what was wrong." On walking up to the Resident-Physician, his face was observed to be somewhat flushed, and he was out of breath. Suddenly he fell backwards to the floor, was quite unconscious, became livid in the face, and breathed stertorously for a few seconds. Restorative measures were adopted, but without avail, as he died in about a minute. The pupils dilated widely at death.

(DRS. GRAINGER STEWART AND DUCKWORTH'S REPORT.)

Sectio Cadaveris (forty-nine hours after death).—Rigor mortis well marked, abundant sugillation on dependent portions of the body.

Pericardium.—No abnormal amount of fluid.

Heart.—Valves competent; left coronary artery at its spring small, hardly admitting a probe in consequence of atheroma of the parts around; right and left coronary arteries pervious, with a few patches of incipient and fully formed atheroma. At the spring of the aorta there was thickening, apparently fibroid, doubtless the first stage of atheroma. It corresponded to a zone above the sigmoid valves, was festooned in appearance, and thickest at the junctions of the coronary valves. The intercoronary valve had a similar thickening below the corpus Arantii, the left coronary valve was a little opaque, and the right one apparently commencing to be thickened. The thickened portion was found to contain fatty granules among the wavy bundles of fibroid tissue, when microscopically examined.

Above the zone were scattered atheromatous patches of various sizes (*e.g.*, split pea or melon seed). In the arch there was atheroma around the openings of the innominate, left carotid, and subclavian vessels. The left carotid was especially contracted at its aperture, being compressed laterally by the deposit.

The thoracic and abdominal aortas contained patches of atheroma. The common carotids, subclavians, and internal carotids were rather rigid and "pipy;" in their coats were numerous atheromatous specks.

Left Ventricle.—The anterior musculus papillaris supporting the anterior (greater) cusp of the mitral valve, looked pale and fatty to the naked eye; when examined under the microscope, fibres of its tissue were found to be so in an advanced degree. In the vicinity of both coronary arteries and veins, the walls of both ventricles were fatty by degeneration, and not apparently by interposition. The supply of blood to the left ventricle had been much impeded in consequence of the thickening at the efference of the left coronary artery.

The pneumogastric nerves were dissected out and found to be normal; both the recurrent branches and those from the descendens noni were perfectly natural.

Larynx and Trachea healthy.

Lungs congested; otherwise natural.

The abdominal viscera were congested, especially the kidneys; in other respects they were quite healthy.

Brain.—Meninges natural, no adhesions, substance apparently healthy; no extravasation or effusion detectible in any part. Medulla oblongata, pons Varolii, etc., natural. The cerebral arteries were not specially examined.

Clinical Remarks by PROFESSOR LAYCOCK.

In this instance, death was due apparently to the narrowing of the innominate, left carotid, and left coronary arteries, which was dependent on atheroma. In such cases, death does not result from ordinary exertion, but may accrue from an extraordinary effort which causes cessation of cardiac and cephalic action.

The term *pseudo-apoplexy* has been applied to these cases.

The comatose condition is due to the sudden cutting off of the supply of blood to the brain.

In this case, the leading symptoms were—first, pain in the thorax and down the right and left arms (chiefly in the left); secondly, pin-point contraction of both pupils; thirdly, a rough, systolic, basic cardiac murmur heard after his admission, but which subsided after rest in the hospital.

These conditions led to the diagnosis that a small aneurism existed at the spring of the aortic arch, which, from his sudden death, was supposed to have ruptured into the pericardium. This view was subsequently abandoned, on learning from the relatives of the deceased, that thirteen weeks previously he had suffered a similar attack, which was speedily relieved by venœsection.

Is there any relation between the nervous phenomena and the existing structural degeneration?

There are two forms of fatty degeneration of the heart. 1. Subserous and external to heart. 2. Interstitial and internal.

These two kinds are often found associated, though one form may be in excess of the other. They do not, however, arise from the same causes. Disease of the coronary arteries is comparatively rare in women, unless they be of advanced age, of intemperate habits, gouty diathesis, or of a masculine nature.

Women more frequently have a weak flabby heart, with external fatty deposit. In bedridden people, cessation of muscular activity entails fatty degeneration in the system, more especially in the textures of the heart. This form of degeneration is seldom uncomplicated, for it is not uncommon to find co-existing lesions—*e.g.*, mitral or aortic valvular disease, dilatation of the heart and adherent pericardium.

Disease and obstruction of the coronary arteries is likewise a common cause of fatty heart. It is not, however, as some maintain, the sole cause of such a condition, for it may occur independently of coronary degeneration; moreover, the coronary arteries themselves are sometimes the seat of atheromatous and calcific changes without concomitant fatty deposit in the cardiac textures.

Fatty heart sometimes occurs uncomplicated with other cardiac lesions, but may be associated with other affections, as for example, in cases of acute tuberculosis pulmonum (of which we have lately had a well-marked example in our wards), with the low condition of lungs, the essence of which is capillary bronchitis, and with hepatic and renal diseases. Whether or not these lesions of the liver and kidneys stand to the cardiac affection in the relation of cause and effect requires investigation.

In gouty affections, fatty heart is peculiarly apt to occur. The more latent forms of gout attack the arterial system of the brain, the heart, and aorta. Angina pectoris is most commonly met with in persons of this diathesis, in fact, three-fourths of the cases of this disease occurring after the age of forty are in gouty people.

A complication or coincidence, as it may perhaps be called, and referred to chiefly by Dr. Stokes, consists in a temporary suspension of the respiratory act. This symptom is, indeed, regarded by some as pathognomonic of fatty heart. Of course a weak heart leads to pulmonary congestion and complications. In a case of hemiplegia now under observation, this peculiar symptom has been well marked This patient suffers from occasional fits of apnoë, which are preceded by some feeble inspirations, while for the space of twenty to forty seconds there is absence of respiration. There is no "*besoin de respirer*" during this interval, and the pulse becomes hurried and irregular. Feeble inspirations then commence, which soon pass into those of an almost stertorous character. The most probable explanation of these phenomena, is that a sentient palsy of the respiratory centre occurs, or a paresis of reflex sensibility in the mucous membrane of the lung, hence the absence of suffocative sensation. Meantime the blood is becoming highly carbonized, and in this condition stimulates the centre to a resumption of the respiratory act. This patient probably had a fatty heart for some time before the occurrence of the hemiplegia, and as he was actively engaged at work as a well-sinker up to the day of his seizure, it is unlikely that there was any important interference with his respiration.

Angina pectoris is the type of cardiac neuralgias. There is, perhaps, only one kind of pain which can be compared to it in intensity—viz., that of phrenalgia or acute melancholia. Cardiac pain is associated with melancholia and imperfect supply of blood to the brain. The neuralgic affections in angina are situated chiefly about the sternum, in the shoulers and arms, more especially, however, in the left arm; sometimes they are seated in the neck.

The pain in these cases can generally be traced to a particular class of nerves; thus, in two cases of vascular bronchocele with exophthalmos in women under our observation, the patients experience the same pains that were complained of in Matchbank's case. In this man, however, there were contracted pupils, while in the cases of the two women there is exophthalmos. Dr. Graves first observed the affection of the eyeballs, and both he and Dr. Stokes consider it due to a cardiac neurosis, Dr. Begbie, on the other hand, attributes it to anæmia. Let us see if we can connect the phenomena observed in the case of the man with those that are manifested in the cases of the two women, or, in other words, differentiate between the contracted pupils and the exophthalmos. The internal and external cutaneous nerves follow the course of the veins of the arm, and end at the wrist. The lesser internal cutaneous nerve (nerve of Wrisberg,) and the intercosto-humeral nerve, are distributed to part of the integuments of the upper arm. All the nerves have origin from the lower four cervical and upper three dorsal nerves; they communicate through the circumflex nerve with the intercostal nerves. Hence the severe thoracic pain which is felt so commonly in angina pectoris. There is no thoracic pain in either of the cases of vascular bronchocele.

The phrenic nerve may be involved mechanically in cases of fatty cardiac degeneration as it has intimate relations with the heart and pericardium; this point, however, has not yet been investigated. The respiration is affected in these cases since an intact state of the phrenic nerve is essential to its normal performance. In the cases of apnoë before alluded to, a lesion of this nerve may have a share in the production of these singular phenomena.

Affections of the eyes are frequently observed in these cases; thus, in Matchbank's case, the pupils were permanently contracted; in the case of a man with aneurism of the arch of the aorta, now in Ward 1, the right pupil is found to be occasionally dilated; in a patient who had sacculated aneurism of the descending thoracic aorta, which lately proved fatal, the right pupil was constantly dilated, while in both cases of vascular bronchocele the ocular affection consists in protrusion of the globe. The staring eye is due, physiologically, to two conditions, one, in which there is a wide opening of the eyelids, due to emotional causes, as horror, surprise, &c.; the other, in which there is actual protrusion of the globe itself. The latter condition may be due to one or other of many mechanical causes, as intra-orbital accumulation of fat, orbital congestion with effusion, congestion of ophthalmic veins, change in the motor muscles of the ball, etc.

simply to nervous influence. Some of the lower animals have special protruding muscles in the orbit; these are probably of the non-striated variety, and on the excessive contraction of these under the influence of the sympathetic, the protrusion of the eye-ball may possibly depend. The contraction of the pupils arises from various causes. I am of opinion that the contracted condition is due to a palsy of the dilating muscle of the iris, which is supplied by the sympathetic, while dilatation is a spasmodic action of the same fibres. Certain spinal lesions affect the pupil, especially those of that part of the chord situated between the seventh cervical and third dorsal vertebræ. This region is called the *cilio-spinal* from its relation to the pupils. Claude Bernard, however, calls it the *oculo-spinal* region from a supposed relation to the lids. He cut the first and second dorsal nerves, and galvanized the proximal cut ends, thereby producing exophthalmos. Experiments show that these nerves have a connection with the eye which we should not expect to find.

What is the relation of the heart to this region? A Jena Professor found a motor centre for the heart in the oculo-spinal region.

In some cases of hysteria, a manifest relation exists between the heart and spinal chord. It, therefore, becomes a question whether the relations of the heart and chord to each other are as cause and effect, or *vice-versâ*.

I formerly taught that the lesion of the coronary arteries was the cause of the angina pectoris, but I have now come to a different conclusion, and am inclined to think that the initial lesion is in the nerve centres, the fatty degeneration being due to defective innervation of the tissues. Deposits of fat on the heart are commonly found accompanying the course of the coronary vessels. The innervation changes which lead to fatty vessels lead also to fatty degeneration in adjacent tissues.

If this theory of causation be correct, we should address our treatment to the nervous system, and by the exhibition of nervines endeavour to act on the motor power of the heart.

For this purpose such drugs as strychnia, digitalis, belladonna, and secale cornutum would be indicated, since they tend to invigorate by contracting the cardiac vessels.

THE BRADFORD INFIRMARY AND DISPENSARY has been recently opened, the alterations and improvements in the building being completed. The total cost has been 4,680*l*. One of the wards is named the "Musgrave," in honour of the late Abraham Musgrave, Esq., who contributed largely to the funds. Another will be called the Rev. Dr. Goodwin's ward, that gentleman having furnished it at his own expense.

NORTH STAFFORDSHIRE INFIRMARY.—The medical staff of the North Staffordshire Infirmary, having invited the medical practitioners of the Potteries to a microscopical soirée held in the committee-room of that institution, entertained a full attendance of visitors on the 28th ult. Several instruments of high power were employed, and an immense variety of objects were exhibited.

VACCINATION.—A return has been issued of the number of unions or single parishes in England and Wales, in which the guardians or overseers have taken measures to enforce obedience to the Vaccination Act. In England out of some 700 replies, only 79 are in the affirmative. To the return "No," signifying that nothing has been done, the remark in some cases is added "nothing beyond posting placards."

KINGSTON LYING-IN HOSPITAL.—We have much satisfaction in announcing that this hospital, which, it will be remembered, was closed a few months since for want of funds, has been re-opened, and patients admitted. The exertions recently made by a few of the residents of the locality have been so successful that enough money has been raised to pay off all liabilities, and leave a margin sufficient to keep the institution in working order without prematurely calling upon the public bounty.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. II.

In proceeding to treat systematically of the Chemistry and Pharmacy of the British Pharmacopœia, we propose not to follow exactly the order of things in the book itself, but to arrange the various articles of the Materia Medica together with the preparations and compounds,—in one alphabetical series,—noticing them *seriatim*, and examining and criticising in each case the processes which are given for their production; we shall also describe the characters by which they are to be recognised or defined, and add such remarks upon their manufacture or chemical properties as may appear to be of general interest.

This arrangement will ensure a due reference to everything of importance, and will enable us to make general observations on such preparations as occur in classes.

ACACIA.—Gum is found in the juices of all plants, but it is met with in its purest form in the transparent tears which exude from various species of acacia. The chemical nature of this substance has, within a comparatively recent period, received important elucidation from the researches of M. Fremy. This Chemist has shown that gum really constitutes the lime salt of an organic acid which he has termed *gummic acid*. Under certain influences, as by merely drying at a temperature of 212° F., this acid undergoes an isomeric modification and becomes insoluble, and it then constitutes *meta-gummic acid*. Both the acids have the same chemical composition—the formula for each being $C_{12}H_{11}O_{11}$, or double these numbers. In fact the acids and their respective lime salts may, indeed, be mutually converted the one into the other. While, therefore, gummate of lime is common gum arabic, the meta-gummate of lime is identical in characters and composition with the bassorin or insoluble gum of the cherry and certain other trees.

It is well known that gum cannot, under ordinary circumstances, be purified from the inorganic bodies it contains, and that upon calcination it furnishes a calcareous ash amounting to 3 or 4 per cent. Professor Graham, however, by the process of dialysis, has succeeded in preparing pure gummic acid from ordinary mucilage, acidulated with hydrochloric acid,—the latter acid with the saline matter passing through the dialyser, and leaving the gummic acid in a nearly pure condition. It may also be obtained by Neubauer's process—acidulating strong mucilage with hydrochloric acid, and precipitating with alcohol.

After two such operations the gummic acid is left nearly pure. Gum is characterised by its solution giving a precipitate, with sub-acetate of lead, with silicate of potash or soda, and with alcohol. It quickly reduces nitrate of silver when exposed to sunlight, and slowly discolours in diffused light. It is soluble in its own weight of cold water, and is so slightly diffusive, that it will scarcely pass through a porous membrane. Its diffusive power is 400 times less than that of common salt. Its solutions become acid by keeping, but they do not ferment.

The powdered gum of commerce is apt to be adulterated with starch, hence the Pharmacopœia directs that it shall not become blue on adding a solution of iodine.

ACETUM.—Vinegar is now ordered to be "prepared from French wines by the acetous fermentation." In the London Pharmacopœia, malt or British vinegar only was officinal; but the Dublin College ordered French, and the Edinburgh Materia Medica contained both French and English.

The change now made is probably of no great importance, inasmuch as vinegar is not ordered in any of the preparations, and we hardly know for what purpose it is introduced among the Materia Medica. Formerly it was used in making Acetum destillatum, Ceratum saponis co., and Linimentum Æruginis; Acetic acid, however, appears now to have entirely replaced it. The advantages gained by selecting French vinegar in preference to English are not very obvious; for the former can scarcely be regarded as being purer, or even more definite in composition than the latter, considering that it is obtained from inferior wine which is unsuited for other purposes, while the latter is specially manufactured from a uniform source. On the other hand, the change is attended by some inconvenience, seeing that genuine French vinegar is somewhat difficult to obtain. It must certainly, however, be said that French vinegar is free from sulphuric acid and is therefore less likely to be open to the question of adulteration.

By far the largest proportion of French vinegar is produced at Orleans, where the process is conducted in large casks, capable of holding from 50 to 100 gallons each. These are arranged upon their ends in rows, one over the other, and maintained at a temperature varying from 75° to 85°, F. The upper part of the casks is left partially open to allow of a free access of air. In the first instance a quantity of good vinegar, boiling hot, is poured into each cask, and every eight days a few gallons of wine are added until the vessels are about two-thirds full. The vinegar is then allowed to remain in this state for fifteen days, when a portion is run off, and fresh wine is put in its place.

The process of acidification goes on much more rapidly in casks which have been used for some time, than it does in new ones. This is probably due to the presence of a gelatinous fungoid growth called *mother of vinegar* (*Mycoderma acete*), which gradually forms in the liquid and favours the change. The production of vinegar from wine depends on the conversion of the alcohol into acetic acid. This is effected by oxidation; the oxygen of the air first abstracts a portion of hydrogen from the alcohol, and forms a compound which is called Aldehyde (alcohol de-hydrogenated), which then itself assimilates oxygen and forms acetic acid. The process is therefore essentially one of slow oxydation or eremacausis; but as pure alcohol is itself incapable of change when in contact with oxygen, the presence of a ferment or some nitrogenous substance in a state of change is necessary, in order to start the action. In comparatively new wine, and also in the malt most used in England, there is sufficient albuminous matter present for this purpose, but in the acetification of alcohol, as practised in some parts of the Continent, it is necessary to add something which shall perform this function. In most cases also the oxidation is quickened by causing the liquid to percolate in a thin stream through a tall vessel filled with beech shavings, while a current of warm air is passing upwards. In this way a large surface of the alcoholic liquid is exposed to the influence of warm atmospheric oxygen.

Wine vinegar contains, besides water and acetic acid, sugar, colouring matter, gum, acetic, and probably other ethers, with a little alcohol and saline matter, especially acid tartrate of potash. The Pharmacopœia directs that it shall be of a straw colour, and have a specific gravity ranging from 1·008 to 1·022. It gives, however, no indication of the amount of acetic acid which should be present. This may range from 3 to 8 per cent., the proportions of acid in the wine vinegar of France. *Proof vinegar* of English commerce contains about 5 per cent. of acetic acid. It is therefore neutralized by a little less than 5 grains of dry carbonate of soda. Good French vinegar is always clear and limpid. It has an agreeable wine like ethereal odour, and a pleasant taste. Chevalier states that its specific gravity should range between 1018 and 1020. The range in the Pharmacopœia is therefore too large for a good wine vinegar. When evaporated almost to dryness it should leave a brownish yellow viscous extract, having a sharp acid taste. This is a very characteristic quality of wine vinegar. The purity of the vinegar is to be ascertained by testing it with chloride of barium, oxalate of ammonia, and sulphuretted hydrogen. The presence of an undue amount of sulphuric acid is *indicated* by the formation of a distinct white precipitate with the salt of barium; and the oxalate of ammonia would throw down the lime, as oxalate of lime, which is insoluble in acetic acid. The formation of a dark coloured precipitate by sulphuretted hydrogen would indicate the presence of some metallic impurity; lead or copper being the most probable. Lastly, it may be said that a solution of nitrate of silver gives but a very slight precipitate with pure wine vinegar.

ACIDUM ACETICUM.—Solutions of this acid illustrate in a very forcible manner the wide discrepancy which exists among the Pharmacopœias of the three Colleges, and the great confusion which resulted in consequence; it enables us also to appreciate the advantages gained from the book now under our notice, and, at the same time, it reveals the difficulties which have stood in the way of its compilation. In the following table are arranged, according to the

strengths, all the acetic acids which were contained in the three Pharmacopœias :—

	Sp. gr.	per cent.
E. Acidum Aceticum	1065	= 85
D. „ „ Glaciale	1065	= 85
D. „ „ Forte	1066	= 51
L. Acidum Aceticum	1048	= 30.8
D. „ „ of Commerce ...	1044	= 28.0
E. „ Pyroligneum	1034	= 21.0
L. „ Aceticum Dilutum.....	1008	= 4.6
L. Acetum Destillatum	10065	= 4.6
D. Acidum Aceticum Dilutum	1006	= 3.5
E. Acetum Destillatum	1005	= 3.0

These are reduced in the British Pharmacopœia to the following :—

	Sp. gr.	per cent.
Acidum Aceticum Glaciale.....	1065	= 85
Acidum Aceticum	1044	= 28
Acidum Aceticum Dilutum	1006	= 3.6

These acids appear to have been well chosen. The Acidum Aceticum is of the strength of ordinary commercial acetic acid, and can, therefore, be easily obtained ; while the Acidum Aceticum dilutum only differs by one per cent. from the previous London preparation, and exactly accords with the Dublin.

No process is given in the Pharmacopœia for the production of Acidum Aceticum, but it is described in the Materia Medica as "an acid liquid prepared from wood by destructive distillation, and containing 28 per cent. of anhydrous acetic acid."

In the manufacture of Acetic Acid, as practically conducted, billets of wood are introduced into large closed iron cylinders, resembling gas-retorts, and submitted to a dull, red heat, for about twenty-four hours. These retorts are connected with a series of condensing vessels, through which the products of distillation are conducted. Large volumes of permanent gases, consisting chiefly of Hydrogen and Carbonic Oxide and marsh-gas, are evolved throughout the process ; and these are ultimately conveyed back by pipes into the fire, and so serve by their combustion to maintain the heat. When all the volatile products have passed over, the charcoal remaining in the retorts is withdrawn, and is allowed to cool in iron cases out of contact with the air. The condensed portion consists of a watery liquid and tar. This liquid contains the Acetic Acid, and also wood-spirit, or Methylic Alcohol, Acetate of Methyl, Acetone, &c. After the tar has been mechanically separated, the acid liquid is submitted to distillation ; the spirituous portion passes over first, and the Acetic Acid afterwards. The crude coloured acid thus obtained, possessing a strong tarry flavour, is known as *Pyroligneous Acid.* To purify this it is neutralised, either with Carbonate of Soda, or with Milk of Lime, but generally the latter. Some of the tar is thus precipitated, and may be removed. The liquid is then evaporated to dryness, and the residue cautiously heated, so as to torrefy the impurities, and render them insoluble. It is afterwards re-dissolved in water, and crystallised. If it is desired to convert acetate of lime into acetate of soda this is effected by adding a solution of sulphate of soda to the lime salt. Double decomposition occurs ; sulphate of lime from its insolubility separating out, and acetate of soda remaining in solution.

The Acetic Acid of commerce is obtained by mixing either the acetate of lime or the acetate of soda, with hydrochloric or sulphuric acid, and submitting the mixture to distillation. In certain cases advantage is taken of the insolubility of sulphate of soda in acetic acid, whereby a nearly pure acid may be at once obtained. The oil of vitriol is allowed to flow quietly under a strong solution of acetate of soda, and the two liquids are then cautiously mixed, so as to prevent any great elevation of temperature. After some time, when the sulphate of soda has entirely separated, the acetic acid may be drawn off, and may be rendered quite pure by distillation.

The impurities likely to be present in commercial acetic acid are, empyreumatic matter, owing to the tar products not having been thoroughly removed, sulphurous acid, sulphuric acid, hydrochloric acid, and traces of lead and copper. Of these, the sulphurous acid is by far the most frequent and most serious. It is produced when the oil of vitriol is made to act upon the acetate ; any organic matter, as the tar products adhering to the salt acts upon the sulphuric acid, and by taking oxygen liberates sulphurous acid, which passes over with the distillate. Under certain circumstances also the oil of vitriol is capable of decomposing a portion of the acetic acid itself, and forming sulphurous acid. To ensure the absence of these contaminations, the Pharmacopœia states of acetic acid that it "leaves no residue when evaporated ; gives no precipitate with sulphuretted hydrogen, chloride of barium, or nitrate of silver, and does not give rise to a blue colour, when added gradually to an equal volume of the solution of iodate of potash, previously mixed with a little mucilage of starch." These tests are sufficient to recognise all the impurities we have mentioned. By evaporation, any fixed saline or organic matter would be detected ; lead or copper would be precipitated by sulphuretted hydrogen, and sulphuric and hydrochloric acids would be indicated by the salts of barium and silver. The presence of sulphurous acid would be recognised by the iodate of potash and starch ; for when sulphurous acid comes into contact with iodic acid, it immediately abstracts from it the oxygen and liberates the iodine, which gives to the starch a blue colour.

Acetic acid is directed to be of a specific gravity, 1·044, and to be of a certain strength as determined by a volumetric solution of caustic soda. As this method of ascertaining the strength of acids is a new feature in the Pharmacopœia, we shall defer our examination of it until we have noticed the glacial acetic acid.

ROYAL COLLEGE OF SURGEONS.—The Hunterian Oration is now delivered biennially in this institution, consequently there was not any discourse on the 15th inst.

THE MEDICAL CIRCULAR.

WEDNESDAY, FEBRUARY 17, 1864.

MEDICAL ETHICS AT COLCHESTER.

In a Profession which is liable to attacks from without, it is essential that the utmost good faith and kind feeling should prevail within. Our remarks are eminently applicable to our own Profession, which, from its very nature, is liable to every kind of malicious misrepresentation, not only from the influence of evil tongues, but from the privacy with which most of our ministrations are necessarily conducted, and the ill-success which occasionally attends our best-directed endeavours. The issue of illness and injury is really not in our hands, but in those of a superior Being, and all we can do is to further the reparative processes of Nature by the aid of science, or to combat morbid actions by such weapons as are placed at our disposal. But there are diseases and injuries which no human power can remedy, and we may add there are patients who are too obstinate or too careless to listen to our injunctions as to the management of their ailments. In either case our cares are sometimes fruitless and our efforts are unsuccessful; and the unfortunate result is too often laid at the door of the Medical practitioner, while it is really due either to the nature of the case itself, or to the carelessness of the patient. But however much we may excuse the ignorance or even the malice of the laity on such points, no such indulgence is called for in the case of members of our own Profession, who are fully aware of the difficulties which beset our path, and who are bound, as far as lies in their power, to uphold the character of their brethren, and even to defend them when they are unjustly assailed by persecution from without.

We lately called attention to a monstrous case of persecution against a member of our Profession in the person of Mr. Peat, a surgeon practising at Manningtree, in Essex, against whom an action was brought by a person named Candler in the Court of Queen's Bench in December last, for an alleged ill-treatment of an injury to the ankle-joint, the result being that a verdict was given in favour of Mr. Peat, who was nevertheless put to great expense in defending himself, and who, by the recent bankruptcy of the plaintiff, is left to pay his own costs. In an article published by us on the 30th December in the last year, we fully explained the groundlessness of the action, and expressed our own astonishment that such a case should ever have been brought to trial, had we not known that, whether from the credulity of some attorneys, or the love of obtaining costs evinced by others, actions the most groundless, frivolous, or malicious, were allowed to come before our Courts of Justice.

But whatever might be the motives existing on the part of the plaintiff or of his lawyers, we expressed a hope that there were no sinister influences at work in the locality where Mr. Peat resides, to create a prejudice against that gentleman, and above all we thought it especially necessary that the members of our own Profession should avoid any interference which might be interpreted as indicating an unfriendly feeling towards a brother practitioner. During the course of the proceedings a letter fell into our hands written by a Mr. J. H. Smith to Mr. Thomas Bryant, of London, which, although a document of no great importance, showed that Mr. J. H. Smith, who is an elderly practitioner in Manningtree, was fully aware of the circumstances under which Mr. Peat was subjected to the annoyance of an action at law. This letter, the authenticity of which is indubitable, distinctly states that Mr. Peat had mistaken a dislocation of the ankle-joint, with a fracture, for a simple sprain, and that this supposed mistake had been an unfortunate circumstance for the patient, whose case had consequently passed beyond the reach of restoration. It is, of course, quite possible that Mr. Smith may have written this letter without an adequate knowledge of the facts, or may have been misled by the statements of the patient; but how much more graceful would it have been in him, living as he did in the same town with Mr. Peat, to call upon that gentleman and learn from him the real facts of the case? And when he learned, as he must have done, that an action was to be brought against Mr. Peat, why did he not offer himself as a witness to bear his evidence as to his knowledge of the matter?

We published Mr. Smith's letter, and, at the same time, expressed our opinion that its contents required some explanation, offering, of course, the use of our columns for the purpose. But, instead of giving any explanation of the letter, Mr. Smith addressed a kind of circular to several of the Journals, Medical and non-Medical, calling us to account for publishing a private communication; and, at the same time, declaring that he would enter into no further correspondence on the subject. As far as we are concerned we committed no breach of faith whatever, in publishing Mr. Smith's letter; it came to us in the ordinary and legitimate discharge of our editorial functions, and it would have been put in evidence at the trial, but for some purely technical objection. Mr. Smith's letter to ourselves, although somewhat offensive, we immediately published being anxious that all parties should have a fair hearing and it was also published in the columns of some of our contemporaries. The 'Lancet' did not publish it, but expressed itself fully satisfied with Mr. Smith's explanation and congratulated him upon having so completely set himself right with his professional brethren.

This opinion of the 'Lancet,' however, was not indorsed by the members of the Medical Profession of Colchester and its vicinity. It appears that there exists in that town a Medical Society, one of the functions of which is to hear and decide upon medico-ethical questions, and to this tribunal, Mr. Peat, himself a member, determined to appeal and, with respect to the matters at issue between himself and Mr. Smith, he made, in writing, the following allegations, which were duly printed and circulated among the

members of the Society, previously to a meeting called to take the matter into consideration.

TO THE MEMBERS OF THE COLCHESTER MEDICAL SOCIETY.

I hereby allege against Mr. Smith that he has been guilty of grossly unprofessional conduct towards me, and I pray the voice of the Society in my favour in the matter.

I allege that he has acted unprofessionally in the case of James Candler of Mistley, a former patient of mine, who sustained an injury of the Ankle Joint, the Tibia being thrown forwards, and the Fibula fractured at its lower end; this case became the subject of an action in the Court of Queen's Bench at Guildhall in the sittings before Hilary Term and a verdict was given in my favour.

I allege that this action was brought by Candler against me, after communication with Mr. Smith; that Mr. Smith told Candler it was a good case for an action, and repeated the same thing to another party or parties, adding, the man was certain of a verdict, and would get hundreds out of me, as I had been wrong in my treatment all the way through.

That he sent a letter to Mr. Bryant of Guy's Hospital, accusing me of having mistaken the accident and treated the injury as a simple sprain.

That he did these things to injure, annoy, and damage me in professional character and pocket; and I again pray your voice in my behalf.

Manningtree, January 19, 1864. THOMAS PEAT.

The meeting, which was a very numerous one, was held at Colchester, on Tuesday, the 9th inst. Mr. Smith, although duly invited, was not present. The following was the result, and we now leave the whole matter in the hands of the Profession.

At an extraordinary meeting of the Members of the Colchester Medical Society held at the Three Cups hotel on the 9th inst., the following resolution was passed:—

Resolved unanimously—That the Members of this Society have heard the charges of Mr. Peat against Mr. Smith, and the answer thereto. That they find Mr. Peat has so far proved his charges against Mr. Smith as to cause them to express, with deep regret, their opinion that Mr. Smith's conduct has been improper and unprofessional.

Colchester, February 9th, 1864.

SUMMARY OF THE WEEK.

DR. TURNBULL AND THE CRAWLEY COURT-MARTIAL.

While Colonel Crawley has been triumphantly acquitted of the charges brought against him, and restored to his command, with its accompanying emoluments, Dr. Turnbull, who, as far as we can understand, has been accused of no definite offence at all, is dismissed from his regiment and placed on half-pay. Some vague imputations of conspiracy and falsification of books were, indeed, made against Dr. Turnbull, arising out of matters connected with the *late* Court-martial, and a most severe opinion was expressed *of his* conduct in a memorandum written and published by the Commander-in-Chief; but on the assembly of a Court-martial held to hear and decide upon these vague imputations, he was fully acquitted, and the charges against him were declared to be false. While, however, Colonel Crawley's acquittal was published to all the world, Dr. Turnbull's acquittal was kept a secret, or at least, an attempt was made to keep it secret, until the 'Lancet' published the result. The sequel of the whole is that Dr. Turnbull, who is fully acquitted, is punished by being placed on half-pay, and dismissed from his regiment; and Colonel Crawley, who is also acquitted, is retained on full-pay, and replaced in his command. Truly in this country, there is one law for the rich and another for the poor; and in Military matters, there is one law for Commanding Officers, and another for their subordinates. We cannot but feel that the treatment to which Dr. Turnbull has been subjected, is calculated to increase the dissatisfaction already existing in the Medical Department of the Army.

THE MEDICAL COUNCIL AND THE CHEMISTS AND DRUGGISTS.

The Chemists and Druggists have lately taken the alarm at what they conceive to be a contemplated infringement of their rights and privileges on the part of the Medical Council. The alarm is, at all events, premature, for the Medical Council are by no means unanimous on the subject of interference with the practice of pharmacy, and the House of Commons would, in all probability, protect the present status of the pharmaceutical body. It must be confessed that the vehement opposition of the greater part of the Chemists and Druggists to the proposed changes, is based, for the most part, on selfish and rather untenable grounds. They are afraid that the Government protection will be withdrawn from secret medicines, to which, in fact, the Government sanction ought never to have been extended; that counter-practice, as it is called, will be limited and restrained; and that those who practise pharmacy will be subjected to some kind of educational test. If all these results were accomplished, there would be no great cause of complaint on the part of the public, although there are persons perverse enough or ignorant enough to believe that quackery ought not only to be permitted but encouraged, and that the counter-practice of druggists is a boon to the community. The fact is, as we have before stated, that the proposition to legislate for the druggists emanates from the Irish section of the Medical Council, whose sympathies are of course in favour of the state of things which exists in the sister island. In that part of the British Empire, no person can open a shop for the dispensing of medicines unless under the authority of the Apothecaries' Hall of Dublin, and we do not know that this prohibition is found practically mischievous. In this country, as is well known, no such prohibition exists, and any person may sell or make up medicines who chooses to do so. Our contemporary, the 'Medical Times and Gazette,' thinks that pharmacy in England is only a trade, and "that any neat-handed lad or woman of ordinary education can be taught to dispense accurately in three months;" that no Government supervision is necessary for this class any more than for railway officials; and that if people are poisoned by the existing system, they have only themselves to thank for the misfortune.

THE CASE OF TOWNLEY.

It will be perceived by reference to our Parliamentary Intelligence, that the case of Townley has attracted very

considerable attention within the walls of Parliament, and that Sir George Grey has proposed to make some changes in the Act of Parliament, by the operation of which the culprit was saved from execution. The changes contemplated are, however, not very important, and seem principally devised for the purpose of throwing off the responsibility of deciding in such cases, from the shoulders of the Home Secretary to the visiting justices of the prison in which a convict is confined. Hitherto, *any* two justices of the peace might certify to the insanity of a prisoner, but now they must be visiting justices of the prison, and the responsibility of selecting the Medical men, whose certificate is indispensable, is imposed upon the same visiting justices. It is also provided that the certificate of insanity, so signed, shall be no longer final or conclusive; but unless we are greatly mistaken, it is not so at present, otherwise we do not see how Townley could have been condemned to penal servitude. With regard to the physicians or surgeons who are to be called upon to certify in such cases, it is only necessary that they should be registered under the Medical Act; and while on this part of the subject we may remark upon a circumstance which, in our opinion, rendered the certificate of Mr. Harwood, one of the Medical gentlemen who signed in favour of Townley's insanity, invalid. It appears that Mr. Harwood has practised for many years as a surgeon, and although fully qualified by collegiate diplomas, has neglected to register under the Medical Act. Although, therefore, the Lord Chancellor has declared Mr. Harwood's certificate valid, we cannot agree with that high authority, unless the following clause in the Medical Act (the thirty-seventh) is destitute of meaning:

"After the first day of January, 1859, no certificate required by an Act now in force, or that may hereafter be passed, from any physician, surgeon, licentiate in medicine and surgery, or other medical practitioner, shall be valid, unless the person signing the same be registered under this Act."

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. I. B. BROWN continues his Clinical Lectures on some "Diseases of Women Remediable by Operation," and his present subject is "Ovarian Dropsy." If the cyst is unilocular, tapping and pressure are sometimes sufficient for the cure, but in many cases the operation of ovariotomy is the only alternative; great care should be taken in the selection of cases, and in the due preparation of the patients before the operation. The operation itself is by no means difficult, and does not require much anatomical knowledge, but the accompanying circumstances, and the after-treatment all require the utmost attention. Mr. Brown describes all the steps of the operation, together with the instruments employed, and it appears that he illustrated his remarks by performing the operation upon a patient, thirty years of age. Dr. BEIGEL continues his papers on "Spirometry," and gives a number of cases from healthy individuals, showing the amount of respiration in each as ascertained by the spirometer. Mr. JOHN GAMGEE, of Edinburgh, relates a case illustrating the "Dangers of Slaughtering Diseased Cattle." He states that a bull, suffering from illness, was slaughtered and sold for food, but the man who slaughtered it, and who happened at the time to have a wound on one of his fingers, was seized with severe febrile symptoms, and died on the fourth day after dressing the bull. Four pigs also died after eating part of the viscera of the animal. Mr. Gamgee declares that such occurrences are by no means uncommon, and that he himself has known of four men who have died, under similar circumstances, within the last four years. He also suspects that many cases of fever are caused by eating of diseased meat, and that the "trichinous" disease is much more common in this country than is generally supposed. Mr. EUGENE GODDARD gives a "Report of the Injuries and of the Post-mortem Examination of a Woman who was lately murdered near Leominster." They consisted of injuries to the head and fracture of the skull, through which, during life, the cerebral matter escaped. The injuries seemed to be inflicted by kicking.

THE 'MEDICAL TIMES AND GAZETTE.'

DR. GARROD continues his Lecture on the British Pharmacopœia, commencing with the antimonial preparations, which are now considerably modified in their forms or their names. The compound antimonial powder is replaced by the Pulvis Antimonialis, consisting of one part of the oxide of antimony with two of precipitated phosphate of lime, the use of the latter salt being by no means apparent. It seems, however, always to exist in the so-called James's Powder. The potassio-tartrate of antimony is changed only in name, the black sulphuret is placed in the appendix, and the oxy-sulphuret appears in the new Pharmacopœia under the name of Antimonium Sulphuratum. The sulphate of beberia or beeberu has been proposed as a substitute for quinine, but on questionable grounds. The Conium, or hemlock, is now used in the form of a tincture prepared from the fruit, usually called the seeds. Large doses of this tincture may be given without producing any bad effect, Dr. Garrod having given as much as a fluid ounce at a dose without the patient experiencing any discomfort. MR. JOHN WOOD continues his papers on "Rupture," his present subject being "Congenital Hernia," the anatomical relations of which he describes with reference to the development of the testes and their descent into the scrotum. DR. H. M. TUCKWELL relates an interesting "Case of Spontaneous Thrombosis in the Left Femoral and Saphena Vein." The patient was in the prime of life, but had suffered lately from fatigue, and he presented a large swelling, with numbness of the left leg, and an indistinct hardness was felt along the course of the femoral and saphena veins. The treatment consisted in the free administration of stimulants, the application of cold, the use of a fracture cradle for the affected leg, and the subsequent employment of graduated pressure. The case terminated successfully, and Dr. Tuckwell observes that it is a rare instance of thrombosis occurring without the existence

any wasting, febrile, or organic disease, and as a consequence of mere debility; and he speculates on the various modes by which the clot formed in the veins may probably be removed.

THE 'JOURNAL OF MENTAL SCIENCE.' Published by authority of the Association of Medical Officers of Asylums and Hospitals for the Insane. Edited by C. L. ROBERTSON, M.D. Cantab., and HENRY MAUDSLEY, M.D. Lond. January, 1864.

The first paper in this number is by Dr. W. H. O. SANKEY, of the Middlesex County Asylum, Hanwell, and is on the "Pathology of General Paresis," a term which has lately been proposed in the Journal as a substitute for that of general paralysis. Dr. Sankey has received, in the female department of the Hanwell Asylum, 2,280 patients out of whom 61 were affected with general paresis; in the male department of the Asylum the cases were rather more numerous, as the disease is more prevalent among males than females. The course of general paresis is usually short, as death occurs in from three to five years, very few patients surviving beyond the eighth year from the first commencement of the symptoms of insanity. Dr. Sankey considers the chief cause of this peculiar affection to be the undue indulgence of the passions, appetites, and lusts, and he shows that the disease is the most prevalent in direct proportion as these feelings are more indulged. Thus it is observed most frequently in the lower classes of males, rather less so in the upper classes of males; still less in females of the lower classes, but not at all, according to the experience of Dr. Conolly, in the females of the upper classes. In the course of a very elaborate series of investigations, Dr. Sankey has endeavoured to trace the pathological characters of general paresis by dissections of the brain in those who have died of the disease; and, although he has not yet examined the whole of the brain substance, he thinks he has discovered certain morbid changes in the capillaries of the cortical substance of the brain which are characteristic of general paresis. "The changes in the pia mater consist in adhesion to the surface of the brain, in varicosity of the veins, in their winding, tortuous, twisted course, and in aneurismal dilatation of the little arteries." He gives some wood-cuts illustrating these abnormal conditions, but he admits that the whole subject still requires much further investigation in order to arrive at definite results. Dr. J. STEVENSON BUSHNAN contributes a paper on "Chance," in which he combats the opinions of those who deny the existence of a supreme creative Being, and a constant superintendence of the moral and physical world. The human mind recognises the distinction between things happening by chance, and things happening by design; and yet everything that happens, whether apparently by chance or by design, occurs in strict obedience to the laws of Nature, held in definite control by an over-ruling influence. Dr. HENRY MAUDSLEY continues his lengthy but very able essay, entitled "Considerations with regard to Hereditary Influence." He traces the mental conformation as well as the physical from the first germs existing in the parents, and leans to the opinion that the maternal feelings exercise considerable influence on the fœtus in utero. He maintains the assertion of the infertility of hybrids, in opposition to Mr. Darwin, and deprecates in-and-in breeding as likely to cause degeneration of race, although this view is contested in some quarters. Mental peculiarities are transmitted from parents to offspring like hereditary diseases, but neither are transmitted directly, but rather in the form of a potentiality in the offspring to manifest certain psychical characters, or to develope certain diseases as life advances. Savage life exhibits a low type of mental organisation, but as nations advance from barbarism to civilisation, the intellectual first, and then the moral faculties become progressively developed, till selfishness expands into family affection, and the latter into patriotism. Children born of vicious parents will inherit the vices of their progenitors, as the young fox will inherit the thieving propensities of the race; and the only method of overcoming this tendency to evil is by implanting the moral elements in the minds of the young. The whole article is full of suggestive matter, and will repay perusal. The rest of the number is filled with a variety of matters bearing upon Psychological Medicines, including a record of cases by Dr. C. L. ROBERTSON, illustrating the "Use of Digitalis in the Treatment of Mania," the writer speaking of this remedy in strong terms of approval.

ERGOT OF RYE IN ALBUMINURIA AND HÆMATURIA.

BY JOHN C. THOROWGOOD, M.D., M.R.C.P.,
Assistant-Physician to the City of London Hospital for Diseases of the Chest.

A few notes of the following case may be of interest in reference to the action of ergot of rye in albuminuria and hæmaturia.

Some time ago I had under observation a man of cachectic aspect, sixty years of age, whose urine was of sp. gr. 1012, loaded with albumen quite red from admixture of blood, and deposited a grumous sediment on standing.

At times pure blood would flow from the urethra before the passage of the urine, and after a few weeks there was a flow of blood after the urine.

He had been sounded, and this gave him severe pain, and was followed by copious bleeding.

At times he had fits of retention, but these not often.

This man had at the hands of myself and others a variety of remedies—for instance: tinctura ferri muriat, Potass: bitart. and ferri potass. tart. Turpentine, Potass. nitrat, et pulv. ipecac co, Infus. krameriæ and gallic acid.

I find by my notes that all these remedies had a fair trial in turn, and some of them did a little temporary good. My impression was that this man had some fungoid growth in the bladder causing this free and obstinate bleeding, the fits of retention, and the very acute pain on the introduction of instruments.

Failing to gain any lasting benefit from any of the remedies above named, I gave him pulv. secalis cornut. gr. ij, to be taken infused in hot water, thrice daily, as soon as it had cooled.

The effect of this medicine was most striking; it soon checked the hæmorrhage, though this returned when the medicine was suspended; at one time the urine remained, under the influence of the ergot alone, for fourteen days quite free from blood, a thing that had never taken place under the influence of any other medicine.

For a time I tried the pure ergotine in place of the pulv. secalis, but did not find it a superior remedy, though both proved medicines of great value in this troublesome case.

This man had no dropsy, no marked lumbar pain, but a very pale cachectic look. The sp. gr. of the urine ranged from 1012 to 1020.

It is now about twelve months since the patient first came under my observation; at present he suffers much and still passes blood; the only remedies that seem to have done good have been the pulv. secalis and the tinctura ferri sesquichloridi, the first being of much more evident benefit than the last.

I would add, in conclusion, that my belief in a fungoid tumour of the bladder as a cause of the bleeding caused me to feel confidence in prescribing the secale, for this agent seems to me to act powerfully on the small blood vessels, and I can fully believe in the efficacy of this medicine either with or without the sesquichloride of iron in such cases as those noted in the last number of the MEDICAL CIRCULAR.

Finsbury Circus, January 30.

GENERAL CORRESPONDENCE.

PURE AIR VITAL—FOUL AIR FATAL.

To the Editor of the Medical Circular.

SIR,—Perhaps to no living Medical authority is the public more indebted than to Dr. MacCormac, M. D., of Belfast, for rendering familiar, as a household proverb, that the pure air of heaven is the first condition of healthful existence. It is the breath of life, as contradistinguished from the breath of man, which entails tubercular consumption and zymotic fevers, proceeding from one common cause, the respiration of air befouled by overcrowding and defective ventilation. We have fevers from famine and fevers from filth, but fevers from foul air may be regarded as the famine of famines to many. In the London 'Times' of the 4th inst., we are informed that 600 or 700 cases of fever have lately occurred in a population of 6,000 or 7,000, at Festiniog, Merionethshire, from overcrowded dwellings, the prolific source of foul, rebreathed air. The inhabitants there seemed to enjoy *all the other* ordinary conditions of a tolerably healthy life—a salubrious atmosphere, food, employment, and temperate habits—not personally uncleanly. Overcrowded dwellings seemed the only sanitary defect, and to such an extent that the beds were never vacant, nor rooms ventilated. One set of labourers slept by night, and worked by day. Another set slept by day and worked by night, so that both alternately breathed zymotic fever poison in their sleep, and were sickened accordingly in large numbers. Baron Liebig states that the blood by reaction—*i.e.*, fever—becomes a means of cure, as a carrier of oxygen, without which vital element morbid matters cannot be destroyed, transformed and removed from the blood; pure air is, therefore, essential for the supply of oxygen, to renovate this "internal atmosphere," "the life of the flesh," which is the sum of all the organs in the act of formation and transformation. The high mortality of fever patients, under unventilated ceilings in private houses and in public hospitals, contrasted with the low mortality in small, well-ventilated, fever sheds, and in thatched cabins, is an admitted fact, from which the new idea of salubrious cottage hospitals, in preference to monster hospitals, seems to proceed. The late Dr. Armstrong, of London, said it was only necessary to remove a fever patient from the foul air of a dark, damp cellar to the pure air of a dry, lightsome garret, and quick recovery would be the result. Fever is not a disease, but Nature's intense animal heat cure, to consume a blood-poison requiring pure air and thermo-electrical sunlight, to support this sanitary combustion of morbid matter.

The late Dr. Graves, of Dublin, said, "Let my epitaph be, I fed fevers,"—*i.e.*, he supported Nature's heat cure for the destruction of pestilential poison, and the renewal of life. So essential is pure air, that the London College of Surgeons require that each recognised hospital should afford 800 cubic feet of well ventilated space to each patient; 1,500 cubic feet of space is provided for each hospital patient in Bermuda, in consequence of the higher temperature of that inter-tropical climate. When "the breath of man is fatal to his fellows," why should one patient suffer from the foul, rebreathed air of another in the same ward? Fancy twelve consumptive patients poisoning each other in one common chamber of a monster hospital, without perhaps ceiling ventilators—living, or rather dying on cod-liver oil, in open opposition to all the laws of Medical science and of sanitary economy. No one with pulmonary consumption, or any tubercular disease, should remain in the large wards of ill-ventilated hospitals, for they are regarded as the special hot-beds of pulmonary pestilence, supposed, in the south of Europe, to be contagious. As troops are congregated, or isolated under an Indian sun, or Russian snow, acute epidemic, fermentable blood-poisons, or chronic tubercular lung diseases, will be propagated in intensity, in proportion to the numbers packed. The question of defective ventilation—of foul air, haunts us in every walk of life, from the cradle to the grave: the anxious mother fancies she cannot keep her child too closely cradled against every draught of pure fresh air; she accordingly contributes to engender the first germs of tubercular consumption, which gradually grow, under favourable circumstances, into maturity, when they claim their victims prematurely for the grave—the fate of 100,000 annually in this United Kingdom, from a preventible cause.

Our ancestors, in King John's time, lived in smoke, for want of chimneys, but we live in a more poisonous invisible smoke, from our own lungs, for want of ceiling ventilators, in our houses, schools, chapels, &c. We hear words of eternal life in churches, where, perhaps, we may be breathing carbonic acid poison from each other.

The inmates of all public institutions and of private houses are as justly entitled to the pure vitalizing air of heaven, and electro-muscular exercise to consume it, in thermo-electrical sunlight, that renovator of all nature, as they are to their daily food, indeed, more so, for they are theirs by divine right, not by pecuniary purchase. What national blunders are over-crowded, ill-ventilated, monster hospitals, &c. Plethoric people, and "those who eat two dinners daily, sit tightly laced in their carriages, and forget to use their legs except in a ball room" (late Mr. Carmichael fancy that carriage airings are sufficient to ventilate them which is mere *surface* enjoyment, such as a horse, refusing to drink water, can have by swimming in it, or as much as a poor cripple on a barrow can have. They who drive in state chariots suffer more or less from a famine of fresh air they are swimming in it, but not consuming it sufficientl for the salutary influence of active electro-muscular exercis which alone endows the iron of the blood with electr magnetic power to attract oxygen from the lungs into the c culation. To conduct all the vital transactions, is an esse tial condition of healthful existence, which they neglect, wh they overload their electro-chemical laboratories of life wi noxious luxuries, that demand fresh air more and mo

From the foregoing we can quickly perceive that fevers c be as certainly fermented by that lethal leaven, the bre of man, as bread by barm. Heat, moisture, and the wa pulmonary vapour of over-crowded, ill-ventilated hous seem to promote both processes. This brings us to consideration of the most perfect hot-bed for fermenti pestilential poisons, the foul, ill-ventilated, and over-crow hot-air baths. There is as much difference between a pu fied well-ventilated hot-air bath, and a foul ill-ventila one, as between a pure current of spring water, and st nant sink water. The former is a salutary luxury, latter a sickening abomination. The public have no se

rity, unless baths be constructed upon such scientific and sanitary principles, as admit of no deception.

I believe the so-called Turkish hypocaust, or more properly, Baker's-oven Bath, owing to its defective ventilation and construction, and, therefore, to its foul air, tends to produce boils, and suffocative faintings, arising doubtless from blood poisons fermented therein. I frequently observed such results, and heard many complain of the offensive effluvia of over-crowded, ill-ventilated baths, as sickening and disgusting. I was called to see a person who remained for eight or ten hours, upon his own judgment, in a hot air bath; he perspired copiously an offensive vapour, became pulseless, exhausted, *cold*, in a hot-air bath, and spasmodically cramped, as if in collapsed cholera, which I consider arose from the respiration of the atmospheric poison of foul hot-air. On being removed immediately into cold fresh air, and treated by alcoholics, his animal heat, animal electricity, and spirits, were restored in a few hours. He was unable to leave his bed for two days from extreme prostration. I heard others complain of sickness, after copious sweat, in such baths. From the letter of "R. Poore," in the 'Dublin Evening Mail,' Jan. 8, it appears that a horse was shut up in an ill-ventilated hot-air bath for two hours and three-qurters, when he became "convulsed," "mad," and asphyxiated, which clearly indicates the poisonous influence, and danger to life and health of foul hot-air baths. Fancy a dozen bath operatees perspiring, respiring, and poisoning each other in such an aerial sink, and you have a perfect picture of a reality where the "breath of man is fatal to his fellows," and stamps them with the seal of premature death. Under the patent purified hot-air bath of Dr. Bolton, of Leicester, we have an improved form, which affords perfect security against the possibility of foul air, or of defective ventilation, from the principle of its construction; for the more you ventilate the more you heat that bath, both being effected by one common process, and the air becomes absolutely purified by high heat, without being burnt, and of this heat there is a constant current circulating in the bath chambers, and carrying off all vapours through ceiling ventilators. Nothing seems more perfect.

Dr. Leared, of London, Physician to the Royal Infimary for Diseases of the Chest, recommends the hot-air bath in consumption, upon his hospital experience of it as a depurator of the blood, and supports my view upon ventilation. "I quite concur with you as to the necessity for perfect ventilation in the bath especially in such cases as phthisis." Sir J. Fife, M.D., also states to me: "The patent of Dr. Bolton, of Leicester, is undoubtedly an improvement which the advocates of the bath must adopt and extend." As hot-air baths may become the cause of disease, as well as of health, it is right that the merits of each form of construction should be briefly reviewed before the Medical Profession. The opinion of so distinguished and practical an authority upon that question as Sir John Fife must be conclusive.

I am, &c.,

Ship, Feb. 12, 1864. J. TUCKER, M.D.

NOTES FROM PRIVATE PRACTICE.

To the Editor of the Medical Circular.

SIR,—As I gather from your remarks that you invite your subscribers to furnish you, from time to time, *with any particulars* of cases which may appear likely to interest *their* professional brethren, I will at once put a few thoughts on paper which have been called forth from reading your valuable publication. In the CIRCULAR, Jan. 6, 1864, an extract from the 'Lancet' is given, conveying some practical hints as to the treatment of several common affections, by Mr. Skey, and amongst others, his treatment of "Ranula" by passing a thread through the middle of the cavity. Without doubting that this may effect a cure, I would mention the plan I have adopted with perfect success, which consists in opening the tumour with a lancet, or bistoury, and having evacuated its contents, seizing the emptied sac with the forceps in the left hand, whilst with the right you apply the argent. nitras with a brisk, stirring movement, so as thoroughly to saturate its interior.

In the CIRCULAR, Jan. 13, 1864, in another review of the 'Lancet' it is mentioned that Dr. James Palfrey communicates a "Report of a Case of Twin Labour, in which uterine action commenced and progressed to the second stage during sleep." This case has brought to my recollection one that I attended nearly twenty years ago, bearing on this interesting point.

May 25, 1845.—Was called up at a quarter to four to attend a Mrs. W., of Kennington (where I then resided), in her first confinement. Her husband stated that she had passed an excellent night, but had sent him for me directly she woke. Living close at hand, I was soon with my patient, but only just in time to take the baby, a fine boy. *a* Surely in this case uterine action must have advanced during sleep. I attended this lady three or four times afterwards, but on no subsequent occasion was her labour so quick.

Feb. 8, 1864.—Having lately attended a case of scarlatina, in which entire suppression of urine occurred after my patient was apparently convalescent, and eventually proved fatal, I send you a brief sketch of it. Renal disorder, leading to dropsical effusion, we know is a very common sequence, but the above, occurring as the result of intense inflammation and congestion of both kidneys, as verified by a post-mortem examination, is in my practice unique, and I have not met with such a case in medical works.

Entire Suppression of Urine, following an attack of Scarlatina Anginosa.—Nov. 13, 1863.—Called on Mr. S——a, aged 22, and found him suffering from a well-marked attack of scarlatina anginosa, and as he had taken an aperient the preceding evening, I at once commenced giving him ammoniæ carb. gr. vj., every three or four hours.

Nov. 14 and 15.—Throat much affected, with great difficulty in swallowing. Ordered mineral acid gargle, and opiate embrocation and poultices; eruption well out, but the fever runs high, and he is at times delirious. Continued the ammonia.

Nov. 16 and 17.—More delirium, resembling the anxiety and restless excitement of delirium tremens. Gave port wine, in gruel, as well as the beef tea he has been taking; and a full opiate, in two doses (each ℥xx of Battley's Liq. opii. sed.), which had an excellent effect, the pulse falling, and the patient gradually recovering his consciousness. From this time for the next week my patient progressed most favourably, sleeping well, taking a little solid food each day, cheerful, and gaining strength. Have discontinued the ammonia, and have been giving Quinæ disulph., gr. ij., bis terve in die.

Nov. 24 and 25.—My patient more feverish, bowels constipated, urine scanty and high coloured, and albuminous. Gave a potash mixture on the 24th, and a Pil. Col. c. Hyd. at bedtime, followed by a dose of castor-oil in the morning, and on the 26th and 27th he was rather better.

Nov. 28.—Patient not so well; pulse about 100, with some return of delirium, and the secretion of urine diminishing each day.

Nov. 29 and 30.—Applied mustard poultices to the region of the kidneys. Continued the potash mixture, besides giving the acid tartrate of potash in barley water as a frequent drink, and small doses of grey powder and rhubarb occasionally.

Dec. 1 and 2.—Patient still delirious at times, and more exhausted; the brain evidently suffering from the poisoned condition of the blood, arising from the suppressed renal secretion, but the weak, rapid pulse, hurried breathing, a brown typhoid tongue, &c., forbid more active, depleting treatment.

Dec. 3.—Patient weaker; passed a catheter, but found hardly any urine in the bladder, and he expired the next day, Dec. 4, three weeks having elapsed since the commencement of his illness, and about ten days since his relapse.

Trusting you will excuse these hurried notes of a painfully interesting case, I am, &c.,

CHARLES HOOPER, Surgeon.

Eastrop House, Basingstoke, Hants.

---

a. The time that elapsed between Mrs. W's waking, and the completion of labour could not have exceeded three-quarters of an hour.

THE THERAPEUTIC VALUE OF MERCURY.

To the Editor of the Medical Circular.

SIR,—Two of your correspondents, Dr. G. Griffith, (MEDICAL CIRCULAR, Jan. 20), and Dr. Sisson, (Feb. 10), have done me the honour to raise some objections against my arguments concerning the internal use of mercury.

Dr. Griffith remarks that Dr. Gooch recommended a five grain blue pill, combined with equal parts of extract of henbane, for several weeks in the treatment of irritable uterus, and that Dr. Wood, of Philadelphia, in cases of typhoid fever, about the seventh or ninth day "knows of no remedy so effectual in such cases as mercury, given so as slightly to affect the gums." The last advice calls to my mind an observation of Dr. Adams, in his translation of the works of Hippocrates, with regard to the use of calomel and opium. "In my young days I knew physicians of the highest reputation, who administered these medicines in scrofula, in cancer—in every case." For what end is the drug to be given in typhoid fever? The tender condition of the intestines would seem most strongly to counter-indicate mercury; and, indeed, with the exception of light nourishment, fresh air, and perhaps stimulants, the best treatment of typhoid fever is to let the patient alone.

With regard to blue pill in irritable uterus, it has been my lot to see mercury frequently given in inflammation of the cervix uteri, &c, but never with any good effect that I could trace. Dr. Graily Hewitt stated also at the Harveian Society (MED. CIR., Dec. 16,) that it was of no service in any puerperal states; an opinion which most will endorse.

Dr. Griffith is himself open to the use of the drug in ulcers of the generative organs and their sequelæ: and he has of late paid considerable attention to the natural history of the disease, when untreated by mercury. The result of this is that he has recently brought forward three cases (MEDICAL CIRCULAR, Feb. 10, p. 109,) in which he believes that bone disease in one instance, rupia in a second, and severe tertiary symptoms in a third, have occurred in the natural course of the disease.

Now the occurrence of syphilitic bone disease without mercury is categorically denied by Syme, Fricke, John Thompson, Weeden Cooke, Hughes Bennett, and Spencer Wells; and Boeck of Christiania has not *seen* it, as the following quotation from "A Synopsis of the Different Treatments of Syphilis carried on in the Christiania Hospital," published at Christiania, 1863, by Dr. Bidenkap, shows.

"The very rare cases, (says Dr. Bidenkap) of tertiary syphilis are met with in patients who have taken a mercurial treatment in other places, especially in foreign parts. Formerly, on the contrary, relapses and obstinate tertiary cases formed the majority of the cases treated at the hospital ..... We may conclude that the exclusion of mercury from therapeutics is the cause of it."

With regard to rupia, Dr. Hughes Bennett says, "This disease I have never met with, but in individuals who have been subjected to mercurial poisoning.

Dr. Griffith was kind enough to allow me to interrogate the patient at the Lock Hospital, the subject of rupia, which was supposed to have been a sequence of an ulcer of the penis, without any mercury having been given. I found that—five years ago the man contracted a sore on his penis, whilst serving as a marine. For this he was treated for *three months* in Haslar Hospital, and took *a mixture with a bitter taste.* About a year ago he had a skin disease, and for this was treated *six months* at the Holloway Dispensary; at present he has the marks of a mild attack of rupia on his face and various parts of his body—no enlargement or induration of any glands—cicatrix of soft sore on penis.

Now, instead of believing that this man's rupia has been a case of natural history of ulcer and secondary, I think many will agree with me when I say that I think the sore (which was a soft one) would not have had any sequelæ, if let alone, but that he probably took three months of bichloride of mercury (in small doses) at Haslar and more at Holloway. And in this case, as Dr. Hughes Bennett asks, how do we know, to say the least, that the rupia was not entirely caused by the mercury?

With regard to Mr. Erichsen's case of bone disease, asserted by him to be syphilitic, I regret that that gentleman has not given any details of the case, for as remarked to me recently by Mr. John Wood, syphilitic bone disease is now rarely met with. Perhaps some of your readers who may remember the case, may supply the history. When such eminent authorities as Syme, Cooke, Hughes Bennett, Skey, Spencer Wells, and Boeck say they have not seen syphilitic bone disease, without a course of mercury, it is incumbent on those who think the contrary to give most ample details.

Dr. Sisson* has been doing me the honour to read a little work I have recently published on this subject, and finds there, in a quotation from Mr. J. S. Mill's "Logic," an argument for giving mercury. I am sure the passage will not bear any such interpretation. Dr. Sisson has stopped at a comma, instead of taking the whole sentence, which is as follows:—

"Recovery from a disease is an event to which, in every instance, many influences must concur. Mercury may be one such influence, but, from the very fact that there are many other such, it will necessarily happen that, though mercury is administered, the patient, for want of other concurring influences, will often not recover; *and that he often will recover when it is not administered, the other favourable influence being sufficiently powerful without it.*"

The part in italics was omitted by Dr. Sisson, but therein lies the point of my argument. For Mr. Allingham's experience and my own ('Med. Times and Gazette,' Nov. 1862, and Oct. 1863) have shown that infantile syphilis is far more curable where mercury is abandoned.

Again, Dr. Sisson is "astonished to my calling attention to the debate on mercury in syphilis" contained in your Journal, Dec. 2 and 16, for he thinks the "whole weight of the evidence was decidedly against the anti-mercurialists."

As I cannot say that I have been much affected by the arguments adduced as yet in favour of the use of even *mild mercurials*, although I hope I am amenable to reason, I would again refer those who are interested in this question to that debate and to the arguments adduced by Dr. Sisson and by Mr. Weeden Cooke, Mr. Sedgwick, Mr. Z. Laurence, also by

Yours, &c.,
CHARLES DRYSDALE, M.D.,
F.R.C.S. Eng., M.R.C.P. Lond.

THE LATE ALLEGED CASE OF POISONING AT HAYLE.

To the Editor of the Medical Circular.

SIR,—In the alleged case of poisoning at Hayle, Cornwall, Dr. Richard Millett, the accused, was liberated by the six County Magistrates at Hayle, February 3rd. The analysis of Dr. Taylor failed to detect poison in the stomach of deceased, who had been buried for three weeks. The was Dr. Millett arrested on Friday evening, at the mansion of his ancestors. There was nothing said about poisoning until deceased's will had been read some days after the funeral, when some members of the family found that Dr. R. Millett, the favourite brother and the youngest, had the property given to him, as the two brothers always lived together. He was in custody a fortnight (three Fridays and every day between), and the chairman stated that the prosecutor had told the magistrate that, even if there were no poison in the deceased's stomach, he had proof enough to satisfy him that he had died of poison, and that the poison had been administered by Dr. R. Millett. Upon that he was arrested; a great number of witnesses were examined about property and other matters, nearly twenty in number, before Dr. Taylor made known the result of his analysis which was read on Friday, the 5th inst., so that all previous evidence went for nothing.

Dr. Taylor said there was no trace of poison. He also gave the contents of the stomach and bowels (a concentrated alcoholic extract), to two dogs, which had been kept hungry

* MEDICAL CIRCULAR, Feb. 10.

They devoured it heartily, but they felt no inconvenience whatever; so here was negative proof that there was no undetected poison in the stomach of deceased. A pint and more of serum issued from the ventricles of the brain, and the ventricles were larger than Dr. Montgomery or Mr. Philip Vincent had ever seen.

Deceased had all the symptoms of apoplexy. He dined at two p.m., on roast beef, vegetables, &c., when he ate four apples and one or two baked apples, drank brandy, ale, wine, and whiskey. His head was 24¾ inches in circumference, and very large behind. His legs were weakly for several months, and his sight almost gone. He walked about after dinner, and about a quarter to five o'clock p.m., when in the drawing-room, he was suddenly seized; he then lay on the sofa, was carried to bed, snored for hours very loudly and died about six o'clock the following morning. There was a jury at the request of Dr. R. Millett, but no *post-mortem*. The verdict was "Death from Natural Causes."

It is even said now, that Dr. R. Millett requested the Coroner to have a *post-mortem*, but he objected, as it was not necessary.

Public demonstration, illuminations, processions, different bands of music, and other demonstrations have taken place in Hayle after the acquittal of Dr. R. Millett; he is a gentleman generally beloved and esteemed.

It is said that his solicitor has issued a writ for trial at Bodmin March Assizes for 5,000*l.* damages for false imprisonment.

If you can insert this letter you will oblige, as you have already noticed this important case in your MEDICAL CIRCULAR, but rather incorrectly, as to poison finding.

I am, your obedient servant,

A CORNISHMAN.

Redruth, Feb. 13, 1864.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

FEBRUARY 5.

THE LAW OF INSANITY.

Mr. BRAND gave notice that on Monday the Secretary of State for the Home Department would ask leave to introduce a bill to amend the Act 3 and 4 William IV., chap. 54, intitled "An Act for the Confinement and Maintenance of Criminal Lunatics."

THE CONVICT TOWNLEY.

On the motion of Mr. Bruce, copies were ordered to be laid on the table of the correspondence which had taken place between the Secretary of State for the Home Department and certain magistrates of the county of Derby and the Governor of the gaol in the county, with reference to the case of George Victor Townley.

THE CRAWLEY COURT-MARTIAL.

Mr. A. MILLS gave notice that he would on the 23rd inst. move that a return be laid on the table of the House, showing the expenses occasioned by the court-martial on Lieut.-Colonel Crawley, distinguishing the proportions to be defrayed from Imperial and Indian revenues respectively.

FEBRUARY 8.

INSANE PRISONERS.

Sir G. GREY moved for leave to bring in a bill to amend the Act 3 and 4 William IV., cap. 54, entitled "An Act for making further provision for the Confinement and Maintenance of Insane Prisoners." After giving an exposition of the present law, under which the recent case of Townley had occurred, he proceeded to state, in very full detail, the circumstances of that case and his own course of action, from the letter he received from Mr. Baron Martin immediately after the conviction of and sentence on the prisoner, calling his attention to the case. He maintained that, upon principles of law as well as of humanity, the learned judge was justified in this intervention; and he asked the House whether, his attention having been thus called to the case, it was not his bounden duty to act in the matter. He explained and justified the steps he took, and read the communications which had taken place in the several stages of the subsequent inquiry with the Lunacy Commissioners, the magistrates, and others, up to the time of the removal of the prisoner to Bethlehem Hospital, which was in conformity, he said, with the uniform practice under the existing law. He then adverted to what had afterwards occurred, and to the evidence which the whole case afforded of the defects of the law, especially in allowing the machinery to be set in motion, not by impartial persons but by agents of the prisoner. He then explained the modifications he proposed to make in the law—alterations which, he thought, would prevent such a miscarriage of justice as had happened in this case. In considering what course should be taken with the prisoner, he had conferred with the Lord Chancellor, who had concurred with him in opinion that, under the circumstances of the case, it would not be right, but would be straining the law, to carry the original sentence into execution.

Mr. MACDONOGH, after reviewing the proceedings in the case, contended that Sir G. Grey had not established a justification; that the words of the Act, "shall be lawful," were not, as Sir George had argued, imperative, but permissive. Assuming, however, that the words were mandatory, the law had been violated, for when the reason of temporary respite had ceased they required (as in an analogous case) that the sentence of the law should be carried into execution.

Mr. NEATE suggested the appointment of a commission or committee that might bring together legal and medical opinions, whereby the law on this difficult subject might be brought into a more satisfactory state

Mr. LOCKE doubted whether the modifications proposed would get rid of the objections to the law. He saw no reason why the sentence upon Townley should have been commuted. Was the same course, he asked, to be taken in future cases?

Sir. G. BOWYER thought Sir G. Grey was not blamable in the case of Townley, but regretted the course he had taken in that of Wright.

After some remarks by Sir B. LEIGHTON,

Mr. BRIGHT said, in his opinion, the statement of Sir G. Grey had made out a complete justification of his whole conduct in this matter, and he believed there was no man in that House who, having been in his position, would have acted differently. Capital punishment was at war with the best and noblest sentiment of the best and noblest of the people. He was astonished that any man was to be found to hold the office of Home Secretary for any length of time, to undergo the agony of deciding upon these cases.

Sir J. PAKINGTON did not think Sir G. Grey could have made more judicious amendments of the law. With respect to the obloquy cast upon him, in his opinion Sir George had not exposed himself to the attacks that had been made upon him. At the same time, he thought the Government had committed a mistake in commuting the sentence on Townley, who had been saved only by a juggle and a trick. By the very Act under which the reprieve was granted the punishment was revived, and justice ought to have had its course.

Leave was then given to bring in the Bill.

LEGAL INTELLIGENCE.

ROLLS' COURT, CHANCERY LANE, FEB. 11.

(Before the MASTER OF THE ROLLS.)

THE ATTORNEY-GENERAL V WALLACE.—JUDGMENT.

His Honour gave judgment in this case, which involved a question of the topographical extent of "London," under the following circumstances. Lord Henry Seymour by his will, dated in 1858, gave the residue of his personal property to be divided between "the hospitals of Paris and London," and the Court was called upon to fix, as far as "London" was concerned, the limits of such a bequest. On the present occasion, the hospitals of four districts, or limits, so to speak, put in their claims, on behalf of which it was contended,—first, that the gift was confined to the hospitals of the "city" of London; secondly, that it ex-

tended to all the hospitals within the limits of the old bills of mortality; thirdly, that it included only the hospitals of the metropolitan boroughs; and lastly, that it meant the hospitals within the limits of the Registrar-General's Report. The Court considered all these suggested limits or districts open to great objection. It was quite evident from the context of the testator's will that he did not mean "London" in its restricted sense, as embracing the city of London only; but that he used the words in its ordinary or popular sense, which meant not only the city of London, but Westminster, Southwark, &c. None of the other limits suggested would meet the difficulty any more than that of the city of London, inasmuch as in all of such limitations, if adopted, many populous districts would be altogether excluded, and many sparsely populated districts, such as Plumstead common, for instance, would be embraced. Then it had been suggested that the limits of the bequest might be taken to include London and Westminster, or the grounds covered by the metropolitan postal districts. But here, again, the first definition would be too limited, the latter too large. The best way of construing the gift would be to hold it as not being confined to any particular metropolitan limits, but to apply to each particular case or claim as it might arrive. The word "London" was a fluctuating term, and in the present instance the London hospitals, or hospitals of London, must be taken to mean the hospitals existing in London in its widest sense in the year 1058, when the testator's will was made. Sir William Petty had spoken of "London" in the year 1686 as meaning not only the heart or city of London, but as London and its continuous streets and districts "within call." This must be the construction put upon the word as used in the testator's will, and "London" must be taken to mean not only the cities of London and Westminster and the boroughs of Southwark, &c., but all of these districts and their continuous streets. For instance, the Consumption Hospital at Brompton must be included as in the bequest. Acting on the principle thus laid down, the Court would deal with each case separately as it arose, and where any doubts existed in respect to any claim put forth, the merits of such claim would be dealt with and sifted in chambers.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 4th inst.:—Richard Wheeler Haines, Bromsgrove; Robert Wills Soper, Dartmouth, S. Devon.

COLLEGIATE ELECTION.—It is stated that the annual election of Fellows of the Royal College of Surgeons of England into the Council of that corporation will lose no portion of the interest attached to these proceedings at the ensuing meeting in July. The names of several gentlemen, both metropolitan and provincial, are already mentioned as likely to be brought forward to supply the vacancies occasioned by the lamented decease of Mr. Green and the resignation of Professor Gulliver; and should no other death, vacancy, or resignation be previously reported, Mr. Hancock will have to retire in the prescribed order, but will of course offer himself for re-election, having only been one year in office.

ANNUAL MEETING OF THE SUBSCRIBERS TO THE BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—On the 3rd inst., the stated annual meeting of the subscribers to the Belfast branch of the above society was held in the rooms of the Ulster Medical Society, 33 High street, Belfast. The attendance was large and influential. Amongst those present were—Dr. Patterson, Dr. Drennan, Dr. Cuming, Dr. Browne, R.N., Dr. Michael Magee, Dr. Keown, R.N.; Dr. Whitaker, Dr. Stewart, and Dr. T. H. Purdon, the permanent president, who did not enter the room until after the business of the day had commenced, and in whose absence Dr. Patterson, a warm and energetic friend of the society, was unanimously requested to take the chair. From the statement made of the past year's proceedings, the working of the Belfast branch of this most useful society presented much that was satisfactory, and evidenced that, as its objects become better known and understood, a larger amount of interest is being manifested on its behalf, both by the profession and liberally-sympathising friends outside of its pale. Dr. Drennan, however, and others, called the attention of the meeting to the fact of several towns which were embraced in the branch's district, (the counties of Antrim and Down), not contributing anything to the funds of the society; and after a good deal of discussion on this subject, and the best means of removing this unaccountable apathy on the part of those members of the profession whose position and means should have made them long since foremost in the society's active support, it was ultimately left in the hands of the committee to be appointed to-day the carrying out of the expressed wishes of the meeting on this head. Dr. Browne, local treasurer, said that it afforded him much pleasure to report to the meeting that the current year's operations had already made a very promising beginning, he having received the following contributions, viz.:—Dr. T. H. Purdon (donation), 25*l.*; do. annual subscription, 5*l.*; Surgeon Doran, Kenmare, per Dr. T. H. Purdon, 1*l.* 1s.; Professor Burdon, M.D., Queen's College, Belfast, 21s.; Dr. Patterson, 21s.; Surgeon MacBride, Gilford, 10s.; Dr. Cuming, 21s.; Dr. Keown, R.N., 10s.; Dr. Whitaker, 10s. 6d.; Dr. Moore, 21s.; Dr. Stewart, (donation) 5*l.*; ditto annual subscription, 21s.; Dr. Hunter, 1*l.*; Dr. Browne, R.N., 21s. The election of a committee of management, to meet quarterly, was next proceeded with, when the following were unanimously appointed:—Dr. Patterson, Dr. Drennan, Dr. Moore, Dr. Thomas Reade, Dr. Cuming, Dr. Stronge, and Dr. H. S. Ferguson, for Belfast; Dr. Ross, Ballymena; Dr. Spearing, Antrim; Dr. John Moore, Glenarm; Dr. Musgrave, Lisburn; Dr. Filson, Portaferry; and Surgeon Patrick, Carrickfergus, for the country. It was then moved, seconded, and unanimously carried, that the best thanks of the meeting be given to Dr. Browne, treasurer, and Dr. Stewart, secretary, for their unremitting attention in the discharge of the duties of their respective offices, and that they be requested to continue their services during the ensuing year. The best thanks of the meeting were also given to the conductors of the several local newspapers for their much valued aid in advocating the interests of the society, and also to the several country members of the committee for their great zeal on behal of the society, together with the earnest request of th meeting that they would persevere in pressing its import ant objects upon both the profession and the gentry i their respective localities. The treasurer's accounts fo the past year having been reported to have been audite and found correct, and Drs. Drennan and Whitaker hav ing been appointed auditors for this year, cordial thank were given to Dr. Patterson for his very dignified conduc as chairman to-day, and his unvarying and substantia support of the society; and thereupon the meeting was de clared dissolved.

THE ALLEGED POISONING BY A SURGEON AT HAYLE.—The inquiry into this protracted case was concluded on Fr day last. Dr. Taylor, to whom had been committed th analysis of the contents of the stomach of the deceased, sa that his death was attributable to an attack of serous ap plexy to which he was predisposed, and that the symptom were not consistent with any form of poisoning within t knowledge of the analyst. The accused was necessari acquitted, and left the court amidst the congratulations his friends—a result which must be satisfactory to his p fessional brethren.

BIRTHS AND DEATHS IN LONDON DURING 1863.—Duri last year there were 2,962 births, and 2,870 deaths registe in the City of London, both numbers being below average of the preceding ten years. Of the deaths thir nine per cent. were of children under five years of age.

THE LONSDALE MEDICO-ETHICAL ASSOCIATION.—T medical practitioners of North Lonsdale have establishe Medico-Ethical Association, one of its fundamental obje being the exposure and uprooting of unqualified preten to medicine.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.—A half-yearly general meeting of the members of this society was held on the 27th of January last, T. A. Stone, Esq. in the chair. It was announced that the petition for a Royal Charter of Incorporation was before the Queen in Council, which will reconstitute the society on a firmer basis than heretofore. The accounts for the year expired were read, when it appeared that a rather smaller amount of relief had been expended than during the preceding year, being as follows:—Grants for Ordinary Relief to Widows and Orphans, 1843*l.* 10s.; Immediate Relief, 21*l.*; towards Self Maintenance of Adults, Orphans, 20*l.*; for extra Relief, 20*l.*; by General Meeting to a Widow, 25*l.*; Total, 1929*l.* 10s. The following gentlemen were elected officers and directors for this year, viz.:—*President*—Thomas Arthur Stone, Esq. *Vice Presidents*—Martin Ware, Esq.; Everard A. Brande, Esq.; Peter M. Latham, M.D.; John Bacot, Esq.; Thomas Turner, M.D.; D. Henry Walne, Esq.; A. J. Sutherland, M.D., F.R.S.; Edward Tegart, Esq.; Geo. Burrows, M.D., F.R.S.; John Miles, Esq.; Sir John Fisher; Cæsar H. Hawkins, Esq., F.R.S. *Treasurers*—J. T. Ware, Esq.; G. Hamilton Roe, M.D. (Atg.); Richard S. Eyles, Esq. *Directors*—J. C. Salisbury, Esq.; Henry Blenkarne, Esq.; T. King Chambers, M.D.; John Clarke, M.D.; Prescott G. Hewett, Esq.; John Morgan, Esq.; J. Gregory Forbes, Esq.; Wm. Munk, M.D.; Barnard W. Holt, Esq.; Charles Miles, Esq.; W. J. Little, M.D.; William Cathrow, Esq.; Henry Sterry, Esq.; Alder Fisher, Esq.; Henry Jeaffreson, M.D.; James Paget, Esq.; H. S. Illingworth, Esq.; Francis Hawkins, M.D.; Thomas Hammerton, Esq.; John Love, Esq.; H. A. Pitman, M.D.; John Adams, Esq.; R. Druitt, M.R.C.P.L.; Edward Tegart, Jun., Esq.—We wish to draw the attention of our readers to the propriety, indeed we may say, necessity, of becoming members of this society, which they can do by applying to the secretary, Dr. Merriman, before the 2nd of March next, for which, see advertisement.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.—At a meeting of the Medical Board, held on Tuesday, the 2d inst., Mr. William Stokes, jun., M.D., T.C.D., L.R.C.S.I., was elected surgeon to the hospital, in the room of Mr. Smyly.

APPOINTMENTS.—J. Montgomery Alston, M.D., University Glasgow has been appointed Surgeon to the Summerlee Collieries, Airdrie.—Dr. Octavius Jepson, Medical Superintendent of St. Luke's Hospital has been appointed Medical Superintendent of the City of London Lunatic Asylum, at Stone, near Dartford, Kent.

SURGEON TURNBULL AND THE HORSE GUARDS.—The following letter is addressed to a daily contemporary:—

SIR,—It must be fresh in the recollection of the public that his Royal Highness the Commander-in-Chief, in the memorandum appended to the "finding" of the court-martial on Colonel Crawley, passed a severe censure on Surgeon Turnbull, implying nothing short of a charge of falsifying the regimental hospital records for the purpose of damaging the character of Colonel Crawley. Few, however, are aware that on the day following the publication of this memorandum, a commission sat at Chatham to investigate these charges. Major-General Eyre presided; and, as the matters to be investigated were some of them of a professional nature, the other members of the court were Inspectors-General Drs. Logan and Anderson, Medical Officers of *high* rank and experience. The result of this inquiry was a *full* and complete justification of Dr. Turnbull's conduct on every material point. Colonel Crawley was present at the investigation, and expressed himself satisfied with the finding of the commission. So far from Surgeon Turnbull having falsified the hospital records, they were found to have been kept in strict accordance with the letter and spirit of her Majesty's regulations. Why is this report withheld? The charge was made in the face of the whole world. Why is the refutation suppressed? And above all, why has Surgeon Turnbull been placed on half-pay? Severe measures were threatened in the event of his guilt being established; he has been fully acquitted, yet he is punished as if the verdict of the court had gone against him. Surgeon Turnbull may not be powerful enough to extort an answer to the above questions; but surely, Sir, the press and Parliament of England are strong enough to see justice done in this case.

MEDICAL CHARITIES.—The following institutions have lately benefited under the wills respectively mentioned, and, as will be seen, to most considerable amounts:—Mr. John Farnell, the head of the firm of Farnell and Watson, has bequeathed to the Royal Orthopædic Hospital 1,000*l.*; the Hospital for Consumption at Brompton, 1,000*l.*; the Asylum for Idiots, 1,000*l.*; and the Cancer Hospital, 1,000*l.* Altogether this gentleman has left to medical and general charities, 22,000*l.* The late Miss Gale, of Andover and Cadogan place, has bequeathed to the Middlesex Hospital, 1,000*l.*; to the Royal Free Hospital, Gray's Inn road, 500*l.*; the Fever Hospital, 100*l.*; the Deaf and Dumb, 500*l.*; the Indigent Blind, 500*l.*; and the Winchester County Hospital, 500*l.*

GUY'S HOSPITAL BIENNIAL FESTIVAL will be held on Wednesday, the 24th inst., at the London Tavern; Alfred Taylor, Esq., F.R.S., in the chair. A long and influential list of stewards promises that the meeting will be one of unusual interest.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, FEB. 17.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Gulstonian Lectures: Dr. Markham, "On the Uses of Bloodletting in Disease;" Junior Medical Society of London, 8 p.m.; Meeting at the Whittington Club, Arundel street, Strand: Mr. J. Warrington Haward, "On the Treatment of Hernia.

THURSDAY, FEB. 18.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Tyndall, "On Experimental Optics," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

FRIDAY, FEB. 19.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Gulstonian Lectures: Dr. Markham, "On the Uses of Bloodletting in Disease;" Royal Institution, 8 p.m.—Mr. W. S. Savory, "On Dreaming and Somnambulism."

SATURDAY, FEB. 20.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, FEB. 22.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, FEB. 23.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Mechanism of Parturition. By Dr. W. Leishman. London: John Churchill and Sons, New Burlington street.

The Insane in Private Dwellings. By A. Mitchell, Esq., A.M., M.D., &c. Edinburgh: Edmonston and Douglas.

Cases in Operative Surgery. By Augustin Prichard, F.R.C.S. Part II. London: T. Richards.

The Dublin Quarterly Journal of Medical Science. No. LXXIII. February, 1864.

Proofs of the Non-existence of a Specific Enthetic Disease. By David Macloughlin, M.D. London: Churchill and Sons.

Ασκληπιος. συγγραμμα περιοδικου της εν Αθηναις Ιατρικης Εταιριας. Μερος Ζ'. Εν Αθηναις. 1863.

The Restoration of a Lost Nose by Operation. By John Hamilton. London: Churchill and Sons; Dublin: Fannin and Co.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

THE SOCIETY FOR THE RELIEF OF THE WIDOWS & ORPHANS OF MEDICAL MEN.—The Report of the meeting has been received, and is inserted.

THE ARMY MEDICAL SCHOOL.—The examination papers have been received.

THE ROYAL INSTITUTION.—The notice has been received.

Dr. ALSTON.—The appointment is inserted.

Dr. STEWART, *Belfast.*—The Report is inserted.

Mr. CHARLES HOOPER.—The paper is received and will be inserted. Our typographical arrangements compel us to omit the diagram which accompanies the paper.

Dr. F. C.—In a brochure upon Hæmoptysis, Dr. Dolmage, Inspector-General of Hospitals, thus explains the infrequent occurrence before the age of puberty of the affection of which he treats :—"Before this period a plethora of the arteries, or an increased flow of humours is determined to the extremities in preference to the other parts of the body; because such a state of the vessels is necessary for the development of the extremities, but after that they are developed, the balance of the circulation is restored; and the pulmonary arteries, on account of their shortness, are most liable to be distended and ruptured by any increased impetus of the blood, more particularly so, if the chest be badly formed, or the vessels naturally weak. Very probably an over-distension of the veins will happen after the thirty-fifth year, on account of the arteries becoming proportionably thicker, and, therefore, better calculated to resist the force of the blood." In reference to hæmoptysis, as it is met with amongst singers and public speakers, he says :—"It generally happens that they, while engaged in their avocation, neglect to breathe with sufficient frequency; hence the blood deprived of its oxygen, as it passes along the different arteries and supplies the various tissues, does not receive an adequate amount in the lungs, where, moreover, there is not the proper quantity of carbonic acid evolved. There is, therefore, retardation of the blood in the chambers of the heart—a stasis of the same in the pulmonary vessels—congestion and engorgement of the lungs, and finally hæmoptysis, particularly if the formation of the chest should not admit an adaptation to the increased distension of the pulmonary vessels."

V. S.—The tungstate of soda is the preparation used to prevent linen, calico, muslin, &c., from taking fire.

A QUESTION.—Can any of your subscribers inform a brother practitioner as to whether there is any Lunatic Asylum in the neighbourhood of London, or failing that, in the country even, where a partially insane patient could be boarded for 50*l.* a-year, or clothed in addition, for 60 guineas, and be employed in *out-door work?* A reply to such question will be particularly and kindly appreciated.—O. B.

Dr. TUCKER.—The second note arrived too late to admit of the proposed alterations being made, and on the whole they are not essential.

DUBITANS.—The subject of the Syphilitic Diseases of Internal Organs is very ably discussed by Dr. Wilks, in the last series of the Guy's Hospital Reports.

MEDICAL ETHICS.

To the Editor of the Medical Circular.

SIR,—A Subscriber would feel obliged, if the experience of the Editor of the CIRCULAR would enable him to answer the two following questions :

1. Is it legal for a Medical assistant (without any qualification), to borrow the name of a surgeon at a distance, to practise with impunity.

2. If not legal, what is the remedy to restrain him from so doing, or the surgeon for lending his name.

[The conduct described is illegal, but we are not clear as to the remedy. Perhaps some of our correspondents may be able to assist us.—ED. MED. CIRCULAR.]

Dr. JEPSON.—The appointment is inserted.

A CORNISHMAN.—We are obliged to omit a few passages in our Correspondent's letter.

Society for Relief of Widows and ORPHANS of MEDICAL MEN in LONDON and its VICINITY.—Instituted 1788.—The Members are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 2nd day of March next, at which Candidates for admission into the Society can be proposed. It is desirable that the form of proposal be filled up and forwarded to the Secretary a few days before the meeting. The form of proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased Members of not less than two years' standing.

The Secretary attends at the Office every Wednesday and Friday, from 4 to 5 o'clock.

53 Berners street, W., February, 1864. S. W. J. MERRIMAN, M.D., Secretary.

The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible or have altogether failed in effect. Imitations having arisen, be particular in the address.

Mental Derangement.—Twickenham House, S.W. Dr. Diamond has vacancies for ladies mentally affected. The house is pleasantly situated in its own grounds of considerable extent, and is about five minutes walk from the Twickenham Station. The highest references will be given. Address, as above.

Coxeter's Illustrated Catalogue, much enlarged, price 1s. 6d., including postage.

Mr. Henry Thompson's Dilator for Gradual Distension of Stricture.

COXETER, 23 & 24 Grafton street East, London, W.C.

Hedges & Butler, Wine Merchants, &c., recommend and GUARANTEE the following WINES;

Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s. and 30s. per dozen.
Good Hock	30s. ,, 36s. ,,
Sparkling Epernay Champagne, 36s.,	42s. ,, 48s. ,,
Good Dinner Sherry	24s. ,, 30s. ,,
Port	24s., 30s. ,, 36s. ,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820 at	120s per dozen.
Vintage 1834	,, 108s. ,,
Vintage 1840	,, 84s. ,,
Vintage 1847	,, 72s. ,,

all of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s.; superior Sherry, 36s., 42s. 48s.,; Clarets of choice growths, 36s., 42s., 48s., 60s., 72s., 84s.: Hochheimer, Marcobrunner, Rudesheimer, Steinberg, Liebiraumilch, 60s.; Johannesberger and Steinberger, 72s., 84s., to 120s.; Brauneberger, Grunhausen, and Scharzberg, 48s., to 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontignac, Vermuth, Constantia, Lachrymæ Christi, Imperial Tokay, and other rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; very choice Cognac, vintage 1805 (which gained the first-class gold medal at the Paris Exhibition of 1855), 144s. per dozen. Foreign Liquers of every description. On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,

London, 155 Regent street, W.; and 30 King's road, Brighton.

(ORIGINALLY ESTABLISHED 1667.)

Kinahan's LL Whisky v. Cognac BRANDY.

This celebrated Old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, andvery wholesome. Sold in bottles 3s. 8d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England: or, wholesale, 8 Great Windmill street, Haymarket.—Observe the Red seal, pink label and cork branded "Kinahan's LL Whisky."

Fine Old Port, Twelve Years in Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Claret 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

A Cup of Coffee in One Minute —DUNN'S ESSENCE of COFFEE, 1s. and 2s. pe bottle. May had everywhere. Warranted to keep good in any climate.

The Medical Circular.

CLINICAL LECTURES.

MIDDLESEX HOSPITAL.

ABSTRACT OF A LECTURE
ON CERTAIN DISPLACEMENTS OF THE UTERUS,

DELIVERED BY

DR. HALL DAVIS,

In the Theatre of the Middlesex Hospital.

Dr. Davis began by an allusion to the means adopted by Dr. Churchill in cases of retroflexion, and he quoted from the recent work of the latter the following observations:—"Some years ago I contrived a gutta-percha pessary, on the principle of distending the posterior *cul de sac* of the vagina upwards, and in some cases it succeeded, but I have since tried those invented by Dr. Hodge, of Philadelphia, and I have found them incomparably better. The vertical limb is passed behind the cervix, and occupying the situation from which we have raised the retroverted fundus, effectually prevents its return.

"But it is not absolutely necessary, as it is not always easy to raise the uterus; the pessary will do that by its steady, gentle pressure, as I have often seen. It occasions no irritation, gives a sensation of almost immediate relief, may be worn for months, and is no impediment to sexual intercourse. I have now tried it in many cases without a single failure. I can most confidently recommend it as the best instrument for the purpose that I have ever seen. It may be made of vulcanite, or of wire covered with gutta-percha; the chief point requiring care is, that it should be neither too large nor too small."

Dr. Davis suggested, as an improvement, that the upper rim—namely, that part of the pessary which directly supports the fundus, should be covered with elastic tubing, and then, that the entire of the vertical portion of the instrument should be encased in an elastic pocket. By these appliances, a greater breadth of surface is presented to the fundus for its support—nor is this surface a hard, unyielding rim, but rather an elastic, yielding and comparatively soft substance—greater comfort is afforded the patient, and all the objects we seek to obtain are better fulfilled.

The purpose of the pessary used by Dr. West is similar to that of Dr. Churchill, and the instrument devised by the Lecturer some time since, is constructed on the same plan.

Dr. Davis showed a pessary, which he had contrived for, and used with success in certain cases. It consists of an elastic ball, to which was connected inferiorly an elastic tube, that served as a channel for the inflation of the ball; the ball uninflated was introduced into the vagina behind the cervix, below the angle of flexure, and in front of the displaced fundus; it was then inflated, the fundus was returned to its normal position, and so maintained by the instrument; an elastic ring was inserted into the vagina, the tube passing through its centre and guiding it to the ball, in such a manner, that the distended ball rested upon the upper surface of the ring, and was supported by it; while in turn, the ring was supported by the rugæ formed below it by the mucous membrane of the vagina.

When the ball is fully inflated the tube is tied and the air thus retained.

Dr. Davis laid great stress upon—as far as possible—doing away with all straps, bandages, tapes, and other appliances, and said that any instrument having for its object the abolition of these, is very much more useful than another requiring them, inasmuch as there is less discomfort to the sufferer, especially if there should be any local hyperæsthesia; indeed, some of the cases where this latter condition exists, cannot tolerate the irritation that would be set up by the use of these appliances.

At this part of the lecture he showed a uterus, bisected for the purpose of demonstrating the condition of the parts, when retroversion and retroflexion are coexistent. He now took up the subject of Retroversion, and commenced by explaining the meaning of the term, which he defined to be a condition of the uterus, wherein that organ is malplaced, lying, in fact, across the pelvis, with its fundus tilted downwards and backwards into the hollow of the sacrum, pressing on the rectum to such a degree as to impede the passage of its contents, but not so as to prevent the finger being introduced, and passed not only to, but likewise above the tumour, that is, above the fundus of the uterus; at the same time the axis of the *entire organ* is made to deviate from its natural direction and the os, high up from the external orifice of the vagina, is tilted upwards above the pubis, in direct ratio with the extent of the depression of the fundus, and thus the os lifted out of its natural bed comes to press upon the bladder.

The differences between retroversion and retroflexion were here illustrated by diagrams of the two affections.

The tumour formed by the retroversion can be distinctly felt in the vagina, pressing forward the posterior wall of that canal.

Predisposing causes to this affection, retroversion, are—first, a weighty fundus; secondly, relaxation of the vaginal supports, and of the uterine ligaments.

The fundus may be weighty and rendered dependent from early pregnancy, that is, pregnancy advanced to the third or fourth month; it cannot, however, be depressed at a later period, because the gravid womb will be too large for the capacity of the sacral curvature, and will be found above the promontory, having ascended with the development of the ovum; or it may be weighty from the growth of fibrous tumours, from moles, or from congestion, or that hypertrophy, which results from repeated attacks of congestion, or from even the congestion occurring at the period of menstruation.

Other predisposing causes are extra-uterine enlargements, which act unfavourably by pressing upon the fundus; we may instance ovarian tumours, and extra-uterine pregnancy, the bulk of the enlargements sufficing to dislocate the viscus.

The retroversion may be gradual or quite sudden.

Jourdan considers a large, roomy pelvis, with a too prominent sacro-vertebral angle, as a predisposing cause. Dr. F. Ramsbotham thinks that a small pelvis, in which the sacral promontory is jutting more than it does in the majority of cases, will be a cause of the malposition in early pregnancy, since the uterus will not be able to rise, and must of necessity remain in the sacral hollow. Jourdan also states, that he has found the displacement more common in thin than in fat subjects.

The uterus, top-heavy from any of the above causes, or being pressed upon forcibly as in the lifting of heavy weights, or as happened recently in the practice of the lecturer, by raising a large, heavy child. Dr. West mentions the case of a woman, in whom the organ was dislocated by strained efforts in raising, or reaching to a kettle.

Again, it may be produced by a blow, a fall, vomiting, or by straining at stool, especially if the bowels be loaded, and blocked up by scybala, by the use of strong

purgatives, especially too soon after delivery. Patients who have been recently delivered, and who have been the subjects of abortion, are particularly liable to the affection, owing to the lax condition of the parts; and they are rendered more particularly so if there should be any force exercising pressure from above. A distended bladder and the forced efforts at micturition consequent on this distension have been pointed out by Denman, and long since recognised by other practitioners as amongst the causes of the displacement.

Prolapse of the posterior vaginal wall, by occasioning or allowing an alteration in the normal inclination of the womb, is mentioned by Dr. Churchill as a distinct cause. The displacement may be the result of scirrhus, as happened in the cases of Mr. Pearson and Dr. Blundell, or merely of delivery, as noted by Dr. Blundell, and by Callisen.

Dr. William Hunter was the first to draw general attention to the existence of retroversion as an accident sometimes to be met with in early pregnancy; in 1808 Osiander of Göttingen, pointed it out as occurring independent of early pregnancy; and four years subsequently the same was demonstrated by Schweighauser and Schmidt, of Vienna; Velpeau also has drawn attention to this fact.

In 1848, Professor Simpson again brought the subject prominently forward. A good abstract of all that is known upon the subject will be found in the last edition of Dr. Churchill's work on "Diseases of Women," or in that of Dr. West upon the same subject.

Symptoms—There may be no inconvenience at all experienced by the person, and the abnormal arrangement of the parts may be discovered only at the post-mortem examination, death having taken place from another complaint. Upon this fact Nauche has laid particular emphasis.

Retention of urine is a most distressing symptom: it may be complete, that is, no water may be able to escape, or it may be incomplete, that is, it may be only partially retained, there being in fact stillicidium. By this in conjunction with a swelling of the abdomen, distinct from the enlargement of the uterus, supposing the patient to be pregnant, we may be thrown off our guard, especially if there be an œdematous condition of the legs; and we may even imagine our patient to be the subject of dropsy, when, in reality, she is suffering from distended bladder, consequent on the pressure of the cervix uteri upon the urethra. We should always be on our guard, when retention of urine occurs in pregnancy; nor under these circumstances should we omit to make a vaginal examination, since by it we are enabled to make out the displacement of the uterus, if that organ be at fault, or to define the distended bladder riding upon the pregnant womb, if such a condition should exist.

Another symptom which will harass our patient is difficulty in defæcation, with or without pain. This is produced by the pressure exercised upon the rectum by the fundus of the uterus; the accumulation of air or fæces in the intestines or of urine in the bladder increases the displacement, and may convert a partial into a complete retroversion.

In Dr. Marcet's case vomiting and constipation were the most prominent symptoms. Sometimes the peristaltic action of the intestines will be reversed, and the vomiting may be of that peculiar character to which the term stercoraceous is applied. If the retention of urine have continued for any length of time we may easily be enabled to feel the distended bladder at or above, as the case may be, the pelvic brim; moreover, should this distension be permitted to remain, and the bladder be unrelieved, its coats will become inflamed, will slough or ulcerate, or may be burst by the over-distending force, and the pent-up urine will then be poured out into the peritoneal sac, and fatal peritonitis be the result. Death may, however, in some instances be occasioned in another manner—namely, by uræmic poisoning, probably from the long retention and alteration in the quality of the urine.

The symptoms, which a vaginal examination will enable us to detect, are an alteration in the axis of the vagina, it being made to look toward the pubis,—a bulging forwards of the posterior vaginal wall, and a partial blocking-up of the vaginal canal by the malplaced viscus,—a tumour lying between the vagina and rectum and across the pelvis,—the os very high up, sometimes, especially in labour, so high above the pubis that it can be reached only with considerable difficulty.

In those cases which are of a doubtful nature we should resort to catheterism, inasmuch as it affords us a most ready means of diagnosis. But in the use of the catheter we must be most cautious; the point of the instrument should be kept quite close to the pubis, because the urethra is very much distorted and displaced by the ascent of the cervix uteri; nor should we apply any but the gentlest efforts in pressing the instrument forwards, lest we perforate the urethra, attenuated by the stretching to which it is subjected.

Diagnosis.—The retention of urine, the difficulty in defæcation, or the obstinate constipation, especially when taken into consideration with the results of our vaginal and rectal examinations, will make the case quite clear.

From Anteversion.—The os uteri in this latter displacement being thrown backwards towards the sacrum, and the retention of urine being not by any means so complete.

From Pelvic Tumours.—By the distinctive characters of such tumours, by the possibility of being able to make out the os uteri, and, indeed, to make out the position of the uterus, especially if it be displaced: we should bear in mind that pelvic tumonrs may be present at the same time that the womb is retroverted.

Dr. Davis stated that he had seen this condition of the womb co-existing with pelvic abscess, and mentioned a case which had occurred in his own practice wherein the abscess extended up to the lower margin of the left kidney, and had thrown the fundus uteri into the hollow of the sacrum.

Nauche relates a case which was one of extra-uterine fœtation, but was mistaken for retroversion, a condition of the womb that did not at all exist, though the viscus was somewhat displaced.

From Ovarian Dropsy.—By the long history attached to the case affected with dropsy.

From Ascites.—Into the error of mistaking retroversion for this form of dropsy we may be led by a coexisisting distended state of the bladder; however, the difficulty of diagnosis vanishes when we remember the slowness with which the abdomen becomes swollen, and how undefined is the tumour when ascites is the malady: by using the catheter we may at once arrive at a true conclusion. The pain or uneasiness usual at the menstrual period is always greater when the womb is retroverted.

Concerning the effects of this lesion of the womb, and the prognosis we should give, Dr. Davis stated, that permanent improvement is prevented by any adhesions which might have formed, and may retain the uterus in its malplaced condition.

Treatment.—The indication first presented is to restore the uterus to its natural position, but before this can be accomplished we must draw off the water, a process—owing to the displacement of the parts—in many instances by means easily effected; however, it is of paramount necessity that the bladder be emptied and never allowed to become distended; indeed, by thus relieving it at short intervals we so free the womb from the depressing and consequent injurious pressure as, in some cases, to allow of its right itself. The bowels should likewise be emptied by warm enemata.

CHLOROFORM.—Professor Nussbaum has succeeded in prolonging the anæsthesia induced by chloroform, by the subcutaneous injection of a solution containing one grain of acetate of morphia. In one case the patient slept two hours, and underwent a painful operation without experiencing any sensation whatever. The injection performed without the previous inhalation of chloroform produced no effect.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. III.

ACIDUM ACETICUM GLACIALE.—This acid is described in the Materia Medica ; and in the second part of the book a process is given for its preparation. It is difficult to understand why the authors of the Pharmacopœia have selected certain things from the Materia Medica, as for example, glacial acetic acid, for a description of the processes whereby they should be prepared; for in the preface we are told that "The Committee of the Council took into consideration the question, whether the late transference of the manufacture of most chemicals from the pharmaceutic chemist to the chemical manufacturer might not be a reason for withdrawing a great part of the chemical processes from the Pharmacopœia. On mature consideration, it was resolved to retain them, and the Council approved of that resolution." It is doubtful, however, if this is a sound resolution; for it would have been more advantageous if processes had been given for those chemicals only which are indefinite in their nature, and do not, therefore, admit of accurate description or easy recognition. But the committee have not acted up to their own decision; they have only given a certain number of processes, and these, as far as we can judge, have not been selected according to any general rule. Why, for example, should a process be given for the preparation of acidum aceticum glaciale, while the production of acidum aceticum is left to the discretion of the manufacturer? Glacial acetic acid is a perfectly definite body possessing characters by which it may be easily known and described ; in fact, its description is given in the Materia Medica. It is to be found abundantly in commerce in a state of great purity, being largely used in the art of Photography. On the other hand, its production on the small scale is attended with great difficulty, and when so obtained is rarely pure.

It is not many years ago that crystallisable acetic acid was regarded as a rare substance, difficult to get, and deserving of careful preservation. But the requirements of the photographer have brought it into extensive demand, and it is now sold by the gallon by every dealer in chemicals. It is only the manufacturer, however, who by operating upon a large quantity of material can thus produce it; and the means which he adopts are not generally known. We believe we are right in stating that scarcely any of the glacial acid of commerce is made in this country, but that by far the largest proportion of it is imported from France and Germany. We know of one or two instances in which chemical manufacturers have unsuccessfully attempted the profitable production of this acid. Yet, to read the process of the British Pharmacopœia nothing would seem easier. We are directed to take twenty ounces of acetate of soda, drive off crystallisation, and then fuse the salt. When cold, to break up the mass, put it into a retort, and add to it eight fluid ounces of sulphuric acid. The energy of the action between the two substances furnishes heat enough to distil over a portion of the acetic acid, but when this slackens we are told to continue the process, with the aid of heat, until six fluid ounces have passed over. We are then to mix one fluid drachm of the acetic acid thus obtained with a fluid drachm of the solution of iodate of potash previously mixed with a little mucilage of starch ; and if it gives rise to a blue colour, to agitate the whole product of distillation with a quarter of an ounce of black oxide of manganese perfectly dry and in fine powder, and re-distil. We will engage to say, from our own experience, that if this process be repeated twenty times, the products will entirely fail in nineteen out of the twenty operations to comply with the description in the Materia Medica. In point of fact it is very rarely, and with extreme difficulty, that *any* glacial acetic acid can be so obtained ; and that the *whole* product should crystallise by cooling to nearly 32° is practically impossible. The quantities of acetate of soda and sulphuric acid ordered are very nearly in the proportion of one equivalent of the former to two equivalents of the latter. In the change which occurs, the two atoms of sulphuric acid unite with the soda of the acetate, and form bisulphate of soda, thus liberating one atom of water and one of anhydrous acetic acid, which combine and pass over as monohydrated acetic acid. But strong sulphuric acid is capable of acting on acetic acid itself, forming, among other things, sulphurous acid and water. This action always occurs, to a greater or less extent; and it is owing to the two last named products passing over with the distillate that the vitiation of the result is principally due. The presence of the sulphurous acid may be recognised by the iodate of potash and starch, as indicated in the process, but we think it will be found rather difficult to remove it by simple agitation with peroxide of manganese as directed.

Acetate of soda is contained in Appendix A of the Pharmacopœia. It contains six atoms of water of crystallisation, which may be entirely volatilised by a heat of about 200° Fah. The salt itself may be heated to 600° without decomposition.

The process which was given for glacial acetic acid in the last Dublin Pharmacopœia was a very good one, and capable of yielding a satisfactory result. It consisted in passing thoroughly dry hydrochloric acid gas through perfectly anhydrous acetate of lead, reduced to powder and contained in a tubulated retort. When the proper quantity of hydrochloric acid had gone into the salt, heat was applied to the retort and the acetic acid distilled off. The principal difficulty here experienced is in drying the acetate of lead ; by

substituting acetate of lime, however, this obstacle may be entirely removed, and the process is then perfectly easy and manageable.

Acidum Aceticum glaciale is described in the Materia Medica as Monohydrated Acetic Acid, and is to possess these characters :—"A colourless liquid, with a pungent acetous odour, converted, when cooled to nearly 32°, into colourless, prismatic crystals, sp. gr., 1·065, which is increased by adding to the acid 10 per cent. of water." The test of congealing by a cold of 32° is not a severe one, for when absolutely a monohydrate, it will solidify at between 50° and 60°. This acid boils at 243° F. Hence, when a diluted acid is distilled, the weakest portions pass over first, and the strongest last. By thus fractionising the products of the distillation of large quantities of acetic acid, the manufacturer can obtain a highly concentrated and even crystallisable acid. For the same reason, vinegar may be, and occasionally is, strengthened by boiling in an open vessel. The vapour of glacial acetic acid is inflammable.

The specific gravity of Acetic Acid, unlike that of other acids, affords little or no indication of its strength. In the first place, a difference in the strength of dilute acetic acid produces only a trifling variation in the density ; and in the second place, the same specific gravity may indicate two different strengths. The latter result arises from the fact that the greatest density is possessed by an acetic acid containing three equivalents of water to one of anhydrous acid. The specific gravity of this acid is 1·079 ; by the abstraction or by the addition of water its density is diminished. In consequence of this anomaly, monohydrated Acetic Acid, and the same acid diluted with an equal weight of water, possess each the sp. gr. 1·063.

For this acid, as for all other chemical substances, the authors of the Pharmacopœia have given a chemical formula : — $H O, C_4 H_3 O_3$. This feature is, at least, remarkable. The object has been, we presume, to define with greater certainty the substances intended to be used. We question, however, whether in certain cases these formulæ have not led to greater uncertainty than would have existed without them. The gain undoubtedly is very slight as compared to the objections to which their introduction is obviously liable. Considering the changes which are daily taking place in the views of chemists, regarding the constitution and nomenclature of compounds, it is extremely probable that many of these formulæ will be out of use, and will, ere long, bear an antiquated appearance. We shall have occasion to direct attention more prominently to them in a future article.

ACIDIMETRY.—In previous Pharmacopœias the proper strength of the acids was ensured by observing whether a certain measured volume was exactly neutralised by a given quantity of crystallised carbonate of soda. This method of operating did not admit of great accuracy, but the result was quickly and easily arrived at. In the British Pharmacopœia processes of volumetric analysis are introduced ; and the strength of the various preparations to be examined by these means is determined, therefore, with much greater delicacy and precision. In examining the acids, instead of weighing out a quantity of carbonate of soda, a standard solution of caustic alkali of known strength is prepared, and this is dropped into the acid, previously tinted with infusion of litmus, until saturation is obtained. The amount of alkaline solution so added is ascertained by dropping it from a graduated tube or burette, which has a scale marked upon it, dividing it into one hundred equal parts. Many forms are given to these burettes by different makers ; that devised by Dr. Mohr being the most convenient, is generally adopted. Different values have also been given to the scale by different operators, but the Pharmacopœia directs that the tube, when filled to O, shall hold 1,000 grains of distilled water. Each division, therefore, will equal 10 grains of water.

To prepare the standard solution of caustic soda, it is necessary to have some means of ensuring the exact amount of alkali it contains. This is effected by means of oxalic acid.

Oxalic acid can be obtained by crystallisation in a perfectly pure and definite condition ; if, then, we weigh one equivalent, or 63 grains, of this acid, and ascertain the number of measures of a solution of soda necessary for its saturation, we know that the volume of solution so added contains one equivalent, or 31 grains of soda. For convenience of calculation, the solution is so prepared that this amount is contained in 100 measures. This is readily done as the Pharmacopœia directs, thus :—"Fill the volumetric tube to O with the solution of soda (the liquor sodæ ordered among the Preparations), and drop this into 63 grains of purified oxalic acid dissolved in two fluid ounces of water, until the acid is exactly neutralized, as indicated by litmus. Note the number of measures (N) of the solution used, and having then taken forty fluid ounces of the solution of soda, augment this quantity by the addition of distilled water, until it becomes $\frac{4000}{N}$ fluid ounces. If, for example, N = 93, the 40 ounces of solution should be diluted so as to become $\frac{4000}{93}$ = 43.01 fluid ounces. The quantity of this solution which fills the volumetric tube to O, includes 31 grains of soda, and will therefore neutralize an equivalent in grains of any monobasic acid."

To determine the strength of the Pharmacopœial acids we have to take a certain measured quantity of the acid dilute it with water, colour it distinctly red with infusio of litmus, and drop in cautiously the volumetric solution soda from the graduated tube, until the colour of the litmu changes to blue. A single drop of the solution is sufficie to change the colour and indicate saturation. Care mu be taken to prevent the solution of soda from containir carbonic acid, for if present it will be liberated during th neutralization, and will cause a change in the colour of th liquid before saturation is completely attained. If an effervescence is observed, therefore, when the alkali added, the liquid should be boiled to expel the free ca bonic acid before judging of the colour.

The Pharmacopœia indicates the number of measures

this soda solution which should be required to neutralize a fluid drachm of each of the stronger acids. Thus, a fluid drachm of acidum aceticum should require 31.5 ; and the same quantity of acidum aceticum glaciale, 97 measures. To ascertain the amount by weight of real acid present, it is only necessary to multiply the number of measures of the alkaloid solution used by the equivalent of the acid, and then divide by 100. Thus 97 multiplied by 51 the equivalent of acetic acid = 4947 ÷ 100 = 49.47 ; the amount of real acid in one fluid drachm of glacial acetic acid.

The method thus given is by far the most accurate means we possess for the valuation of acids ; and if the solution of soda is perfectly caustic, the operation is performed with great rapidity, ease, and certainty.

IRISH MEDICAL "MEMS."

(From our Dublin Correspondent.)

It is a surprising but certain fact, that there are few who have laid claim to the honour of an invention, or the perfection of any branch of science or art, who have not had their rights questioned, and have had competitors who claimed a priority of discovery. While amidst the refinement and advantages of London society, Sir Humphry Davy was conducting his experiments on the safety lamp, but far away in the north of England, buried in the obscurity of a collier's village, another mind had conceived the same idea, and brought it first to perfection, yet did not obtain the credit which he deserved, and instead of George Stephenson's lamp being universally known, there are few perchance who ever heard of it, while the invention of his rival has now become almost a household word under the name of the Davy Lamp. Thus, though Dr. Frost has obtained the credit of discovering the anæsthetic property of chloroform, and conferred an everlasting boon on suffering humanity, there is another who has claimed to have forged the first link in the chain which Dr. Frost only continued ; and now when a London Surgeon prides himself on being the first who successfully performed the operation of ovariotomy in Ireland, up starts a rival in the shape of Dr. Thompson of Lisburn, an Irish country practitioner. Dr. Thompson performed the operation in May, 1848, on a woman named Lemon, the wife of a carpenter residing at Ballylesson, in the county Down, and up to the present time she is said to be enjoying perfect health, so that he has to all appearances incontestably established his claim.

Nihil *sub cœlo perfectum* is a motto sanctified by antiquity, and the recent law passed for the registration of births, deaths, and marriages in Ireland does not controvert this. The form of certificate for a death would certainly require a change. In its present form it requires the medical man to certify to a fact of which he cannot be aware, unless on the authority of the friends of the deceased, namely, that the patient died on a certain day. Now many cases may arise either of insurances or annuities, where it may make a material difference as to what hour and day the patient died. Thus he or she may have ceased to exist on the 31st of December, 1863, or the 1st of January, 1864, and how is the medical man to certify to this?

At first sight this may seem to be mere hair-splitting, but such is far from being the case, and many medical men have refused to sign certificates on this ground. The dispensary surgeons receive a shilling for every certificate presented to them, and this emolument will increase somewhat their wretched salaries, though it inflicts the loss of time and some trouble on the general mass of practitioners, who think that those who give the certificates should get the shilling, on the principle that the labourer is worthy of his hire.

The Army Board have decided on receiving the diploma of the Apothecaries' Company of Ireland as a medical degree, and in consequence of this arrangement there is every probability of the directors of the Hall raising the fee for their diploma from ten shillings to five pounds.

The honour of knighthood has been conferred on Dr. Wilde, Surgeon-Oculist to the Queen in Ireland, as the Lord-Lieutenant happily expressed it, not in recognition of his high professional reputation, which he declared to be European, and thus needed no further eulogium at his hands, but to mark his sense of the services which he rendered to statistical science, especially in connection with the Irish census. Dr. Wilde is favourably known to the literary and medical public on this side of the channel as a ready writer, learned antiquarian, and skilful oculist.

Amongst the many works which have issued from his pen I may particularly mention his works on "Austria : her Medical Literature and Scientific Institutions," "The Closing Years of Dean Swift's Life," "The Beauties of the Boyne and Blackwater," and the "Popular Superstitions of the Irish Peasantry." His principal works as a medical writer are—"Practical Observations on Diseases of the Ear," and an "Essay on Otorrhœa ;" he has also contributed largely to the Medical Journals. He has likewise endowed an hospital called St. Mark's for diseases of the eye, where medicine and advice are gratuitously supplied to the poor.

The suit pending between the King and Queen's College of Physicians has not as yet concluded. The Master of the Rolls has not delivered judgment, and no matter what his decision may be, it is generally believed that the case will then be referred to the House of Lords. The latter, too, may be turned, and there may be a suit of College of Physicians *versus* Trinity College, on the ground that the latter have no legal claim to monopolise the rights of the College of Physicians by granting a license in medicine.

During the past few years death has reaped a rich harvest of medical men, and we have had to deplore the loss of some of our most eminent members ; and even within the last six months there followed in succession the deaths of Drs. Power and Neligan, Smyly and Osborne. By the demise of Surgeon Smyly the vice-presidentship of the College of Surgeons became vacant, and Dr. Jacob, Professor of Anatomy and Physiology, has succeeded to the office.

An elegant and graceful tribute was paid by Dr. Stokes to the merit and virtues of his deceased colleague, to his ability and skill as a surgeon, and the numerous friends and admirers of Surgeon Smyly have decided on endowing a children's ward in his name in the hospital of which he was so long an ornament.

Popular indignation has not as yet quite subsided here about the respite of Townley, though the letters now published of the whole proceedings have cleared up some startling points in the transaction. It seems highly apocryphal that Dr. Forbes Winslow should have given his evidence and advice without the usual fee given to a skilled witness, and it is very much questioned whether he would have done so had the offender been a man of lowly station. He who first represented the statue of Justice with her eyes veiled must have done so in the spirit of satire, perhaps after experiencing but poor justice at her hands ; and certainly this case will fully establish her allegorical delineation.

THE CLARE COUNTY LUNATIC ASYLUM, now being built at Ennis, is upon a site of forty acres, the front facing the south. It consists of a front centre building, containing the official residences and public rooms. There are wing buildings for patients and the infirmaries, and a rear central building containing dining hall and other offices. The wide corridors, usual in other asylums, are here avoided with a view of assimilating the arrangements to those of ordinary life, which are considered preferable to the ordinary corridor or "ward system." Accommodation is provided for 260 patients. The infirmaries are sufficiently capacious to contain about one-third of that number. The total cost is estimated at 29,000*l*.

THE MEDICAL CIRCULAR.

WEDNESDAY, FEBRUARY 24, 1864.

THE PLEA OF INSANITY IN CRIMINAL CASES.

The recent discussion in the House of Commons on the occasion of the introduction of an amended Act, referring to the treatment of insane prisoners, proves the increasing interest taken by our modern legislators in the subject of insanity, in its connection with the commission of crime. In the late case of Townley, there were no doubt many opinions arrayed on both sides of the question, having but little reference to the sanity or insanity of the accused. Some advocated the view of his insanity, merely with the object of averting the capital punishment, which the proof of soundness of mind on his part would necessarily involve; and many clamoured loudly for the opposite view, perhaps to show their contempt for the "mad doctors," and for theories of insanity in general. One of the members of Parliament remarked, truly enough, that as soon as Townley was sentenced to penal servitude, nobody took any further trouble to question his sanity, although, supposing him to be insane, it was just as cruel to condemn him to the public works for the rest of his life as to hang him. Some people, too, probably took up the matter as a political question, in order to damage the Home Secretary.

It is, therefore, satisfactory to find that the discussion on the subject in the House of Commons was conducted in a very fair and unprejudiced spirit, and without any political animosity. Still more is it gratifying to observe that the Medical Profession were not much abused, but on the contrary it was admitted that in determining questions relating to the mental condition of prisoners or convicts, the opinions of Medical men ought to be received as a necessary element in the inquiry. The time has probably already gone by, when any persons bearing the character of gentlemen, could believe that the members of the Medical Profession, as a body, would pronounce a person insane, or the contrary, from mere sordid and pecuniary motives. Differences of opinion, it is true, may exist, but these discrepancies arise from the difficulties inherent in the subject itself, and, it may be added, they are increased by the mode in which trials involving questions of sanity or insanity, are conducted. Medical witnesses, like the barristers and the attorneys, are marshalled on both sides of the question; and, precisely as in the case of the law, the party who has the longest purse will get the best advice. The poor unfortunate wretch Burton, who was hanged last Spring, and who was undoubtedly insane, was unable to procure the services of Medical experts, and was therefore left to his fate; but young Crœsus, if suspected of crime or insanity either, can obtain the highest legal or medical talent which the empire can afford. The consequence is, that young Crœsus has a fair trial, and the poor young idiot has not; and so far it is true that there is one law for the rich and another for the poor, but only in the same sense that the rich man can get a dinner whenever he likes to order it at the London Tavern, and the poor man is often obliged to go without any dinner at all. Hunger and the want of law are necessities to all alike, but to satisfy these necessities is easy enough for one class and very difficult, if not impossible, to the other. Some people may perhaps think that a poor idiot ought to have the services of Medical experts as well as a rich idiot, but such a question would necessarily involve the fundamental doctrines on which distinctions in life, with all their attendant advantages or discomforts, are essentially based.

It is impossible not to notice that all the speakers in the House of Commons, and many of them were men of great ability, exhibited an utter want of knowledge of what is called psychology, and of the morbid conditions of the human mind. They all discoursed fairly and sensibly, and some of them feelingly and eloquently, upon the general bearings of the subject, and as to the machinery by which questions of criminal responsibility should be determined, but not one of them showed that he had paid any attention either to the literature of insanity, or to the practical study of mental disease. This circumstance perhaps ought to excite no astonishment when we reflect that there are hardly any Medical men in the House of Commons, and that of the Medical body itself, there are not many who profess any special devotion to the subject. As to the general public, including of course, the members of the Legislature, it cannot be expected that they should pore over the pages of Pinel and Esquirol, or that they should, as amateurs, study for years together in the wards of a lunatic asylum, but we might at any rate expect that they would abstain from giving flippant opinions upon the doctrines held by such illustrious practitioners as those to whom we have alluded, and by others who have had large practical experience in the diagnosis and treatment of insanity. According to the notions of some people, one man is as good a judge of what constitutes insanity as another; and yet if a person who advanced such a theory were a watchmaker or an engineer and he were told that everybody was an equally good judge of the mechanism or the derangements of a watch or of a steam-engine, he would ridicule the idea. So we find that thoughtful and studious men, who have spent days and years in solving the mysterious problem of human responsibility and irresponsibility, are ridiculed by any upstart who thinks that he has acquired, by intuitive perception, a power of judgment which the other does not yet even pretend to possess, so "fools rush in where angels fear to tread."

Such was not, however, the feeling or the temper of the House of Commons in the late debate, when it was fully admitted that the whole subject was encompassed with difficulties, and that neither Medical men nor lawyers, either in their combined or separate capacities, were equal to its solution. Mr. Scourfield remarked that unless the opinions laid down by Medical men were closely watched, they would be attended with the most dangerous consequences; and he also observed that the Medical man and the lawyer necessarily looked at the question of insanity in different light

"The doctor was bound to consider the welfare of the patient, and the mode of curing him. The lawyer, on the other hand, was bound to consider the interests of the community at large and the safety of the public. It was most important in his opinion, that in determining who was and who was not insane, the legal opinion should not be subordinated to the medical." Sir George Bowyer made the following observations, which are well worth attention:

"He objected to the joint commission composed of physicians and lawyers, because he thought that the two classes of men would, to a certain extent, act at cross purposes. The legal and medical ideas of insanity were quite different. Physicians would examine a man's sanity with reference to the condition of his brain, while the only question which would present itself to the mind of judges or commissioners in deciding whether a man was sane would be, was his state of mind such that he was responsible for his actions? A man might have something morbid in the recesses of his brain and still be sane for all practical purposes and amenable to criminal law. A man, on the contrary, who after sentence fell into a state in which he became unconscious of his actions, was justly exempted from punishment, being, in the words of a great authority, 'sufficiently punished by the insanity with which he was visited by Providence.' The only constitutional method of testing whether a man had become insane after his conviction was, in his opinion, trial *by jury*. But whether the fact were established by the decision of a jury or of a commission, Medical men *ought* to appear as experts, and not as judges. The great defect of the present day was that Medical men appeared not as witnesses, but as advocates; if set in motion for the prisoner, their object, disguise it as they might, was really 'to get him off.' The question of sanity, if raised at all, ought to be treated by parties having no interest in the case other than the elucidation of truth; and he thought it might be worth considering whether the Crown ought not to appoint professional gentlemen of high standing who would deliver their opinions officially—of course receiving a proper remuneration."

On the whole, we wish that Sir George Grey had not pressed on his measure in its present state. It has been prepared in a hurry, and owing to the pressure occasioned by an individual case, the like of which it is not probable will soon recur. The subject has now received in Parliament the attention which it deserves, divested of that amount of prejudice and passion with which it was treated out of doors. It is the more necessary to delay the passing of the measure, because it is applicable, in its present form, only to England; and if it is necessary at all, why is it not equally necessary to Ireland and Scotland? The Medical Act, notwithstanding the diversities of local customs and institutions, was made applicable alike to all parts of the kingdom, and surely a measure affecting criminal lunatics must be quite as essential in one part of the British Islands as in another.

Since the above was written, another discussion on the subject has taken place on an amendment being moved to one of the clauses in Sir George Grey's bill. On this last occasion, many of the members of the House of Commons abused the Medical Profession in the old style, but they did not have it quite their own way, and one of them (Mr. Neate) was even bold enough to question the definition of insanity as laid down by the Judges, and stated that three cases of hopeless insanity had been reported to him by Dr. Forbes Winslow, in all of whom there existed a knowledge of right and wrong, and all of whom were, therefore, in the legal sense, responsible for their actions.

SUMMARY OF THE WEEK.

THE PHARMACOPŒIA AND THE PHARMACEUTICAL SOCIETY.

The British Pharmacopœia appears to gain but little favour from any quarter, and its production, after so many years of anxious expectation and such enormous expenditure of money, resembles, in some respects, the birth of the mouse after the parturient agonies of the mountain. Nevertheless, as the volume has received the sanction of the government, it is imperative on all Medical practitioners and pharmaceutists in the British dominions, to make themselves thoroughly acquainted with its contents, however difficult it may be to obey many of the formulæ which it contains. The orator at the Royal College of Physicians has pointed out that some of the novelties introduced are useless, and others injurious, in a Medical point of view; and at a recent meeting of the Pharmaceutical Society, Dr. Redwood attacks the Pharmacopœia from another and a practical aspect. He complains, and not without justice, that the names and the composition of many bodies have been altered without any sufficient cause, thus creating a great amount of confusion to the preparers and dispensers of drugs, and that formulæ have been published which it is impossible to adopt. Thus, for instance, in that *pons asinorum* of the pharmaceutical chemist, the spirit of nitrous ether, the compilers of the Pharmacopœia have proposed a plan for its preparation, which, as they imagine, will ensure the production of a pure article, but it turns out that the nitrite of soda which they direct to be employed in the preparation cannot itself be procured by the processes described, and the consequence is, that the spirit of nitrous ether, prepared in the new way, is *worse* in quality than the former much abused but very popular article!

DR. TURNBULL AND THE CRAWLEY COURT-MARTIAL.

We last week gave currency to a report which appeared in the pages of several of our contemporaries, to the effect that Dr. Turnbull, having been fully acquitted of the charges brought against him, had been dismissed from his regiment and placed on half-pay. It appears, however, tha the latter part of the report is untrue, and Dr. Turnbull has contradicted it himself. He is retained on full pay, and if the condition of the Inniskilling Dragoons be such as some persons have described, perhaps he will feel rather relieved than otherwise at being removed from the regiment, and left at liberty to exchange into another. It has been justly argued that as the Commander-in-chief published his memorandum, embodying a censure on Dr. Turnbull, the minutes of the Court of Inquiry, which fully exonerated that gentleman, ought to be published likewise, and it is very truly represented that the expressions used in the memorandum amount, under the circumstances, to a libel in point of honour, if not in point of law, and ought to be explained or apologised for accordingly. As to Colonel Crawley, if it be true that his expenses to England and back have been defrayed by the Government, and that he has

received full pay and allowances, and quarters, all through the period of his trial, he will have suffered as little in purse as in reputation, and can have no great cause of complaint as to his voyage to England. All his expenses, in fact, were paid, except the legal ones, as courts-martial do ot recognise lawyers.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. PRESCOTT HEWITT gives a Clinical Lecture on "Caries and Necrosis of the Bones of the Skull," founded upon two cases of that disease which occurred in the practice of St. George's Hospital. Mr. Hewitt reviews at some length the causes of these diseases, both accidental and constitutional, and he states that syphilitic caries and necrosis are the commonest of all the diseases of the cranial bones, but they were much more common formerly than at present, the difference being probably due to the more cautious administration of mercury in recent times. With regard to the question whether there are any characteristic signs by which syphilitic disease of the bones of the skull can be recognised, Mr. Hewitt replies in the negative, although many distinguished modern pathologists hold a different opinion. Mr. JAMES R. LANE contributes a paper on "Vesico-Uterine Fistula," founded on a case in which pregnancy occured after closure of the os uteri by operation. The case itself has already been published, so far as its early history is concerned, but the after-consequences are now particularly described. It appears that Mr. Lane performed the operation of closing the os uteri in order to relieve the patient of the incontinence of urine, the fistula existing between the bladder and the canal of the cervix about half an inch above the os. The operation was quite successful, and the patient menstruated by the bladder; but the curious circumstance was, that she became pregnant, although the os uteri was to all appearance closed. The tumour formed by the fœtus was naturally enough mistaken for an accumulation of the menstrual fluid, but the expulsion of a fœtus of about four months explained the real state of the case. The vesico-uterine fistula, however, was now re-established, and the same operation as before was practised with the same success, and no subsequent pregnancy occurred, menstruation being again performed by the bladder. Dr. G. D. GIBB gives a short paper on "Albuminuric Aphonia," by which Dr. Fauvel, of Paris, designates a peculiar œdema of the vestibule of the larynx and vocal cords, preceding or following albuminuria, and more often present without any external manifestation to afford even a suspicion of the existence of Bright's disease. Mr. HENRY THOMPSON communicates a paper on "Lithotrity without Injections," in which he states that he has for some time past practised the operation without preliminary injection of the bladder, and almost without any injection subsequent to the sitting. Mr. Thompson explains his reasons for this new mode of practice.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. GARROD commences his Third Lecture on the "British Pharmacopœia," but we have already given a full abstract of the topics introduced, in our Number of the 10th inst., the notes having been furnished by our own Reporter. Dr. HARLEY continues his Lectures, delivered in University College, on the "Urine and Diseases of the Urinary Organs." In the present lecture he describes the solid inorganic and organic constituents of normal human urine, and their varying amount under different physiological conditions. He shows that even national habits cause a very great diversity in the amount of the solids of the urine, the quantity being greatest in that of the German, less in that of the Englishman, and least in that of the Frenchman. The examples are taken respectively from Lehmann, Becquerel, and Dr. Harley himself, and the difference is accounted for by the fact that the German eats most largely of all kinds of food, the Frenchman eats least of animal food, and the Englishman's diet is of a medium kind. In pregnancy, the excretion of the solids in the urine is diminished in proportion to the nearer approach of delivery, the explanation being that the development of the fœtus withdraws more and more nutritive material from the mother's circulation. Dr. J. W. OGLE communicates some "Cases of Epilepsy, Convulsions, Giddiness, &c., being part of a Series illustrating Affections of the Nervous System of Organic or Inorganic Origin, with Clinical and Pathological Observations." The cases are of a miscellaneous kind, some requiring aperients, others sedatives, and others tonics, according as the symptoms pointed to congestive disease, or exhaustion of the nervous centres. Mr. EDWARD J. WARING, of the Indian Medical Service, contributes a "Notice of the Ægle Marmelos," a plant which furnishes the Bela or Bael of the British Pharmacopœia. This substance, as is well known, is very much esteemed in India in cases of diarrhœa and dysentery, but it has hitherto been but little employed in Great Britain. It is obtained from the above-named tree, belonging to the natural order of Aurantiaceæ, and all parts of it have been used in Indian practice. The fruit, however, is considered to be most serviceable, and appears to owe its properties to tannic acid, a concrete essential oil, a bitter principle, and a vegetable acid.

THE 'BRITISH MEDICAL JOURNAL.'

Mr. BRODHURST continues his Lectures on "Orthopædic Surgery," his present subject being the Curvature of the Spine, and especially the lateral curvature, or scoliosis, which two drawings are given in illustration. The treatment of such cases is preventive and curative, the former being directed to develope the body in youth in a healthy manner, and the latter being of two kinds—namely, constitutional and mechanical. Dr. ROUTH commences a Course of Lectures delivered by him before the Medical Society of London on "Some Points connected with the Pathology and Etiology of Fibrous Tumours of the Uterus." Dr. W. H. O. SANKEY contributes some "Illustrations of the Different Forms of Insanity," his present subject being

hypochondriasis as a form of melancholy. He relates a number of cases which have fallen under his notice, illustrating the delusions which often characterise this kind of insanity. Mr. GARRAWAY contributes a short paper on a case illustrating the "Action of Ergot, and the Resuscitation of Still-born Children." In the case recorded, the ergot appears to have acted beneficially, but the child was still-born, and could not be resuscitated.

Ασκληπιος. Συγγραμμα περιοδικον της εν Αθηναις Ιατρικης Εταιριας. (Asclepios, a Periodical Journal of the Medical Society in Athens.)

We received a number of this periodical last year, and noticed it at the time, and now the number for April and May, 1863, has come into our hands. It may surprise some of our readers to learn that a Medical Society exists in the capital of modern Greece, and that a Medical Journal is regularly published in the modern Greek language, which differs very slightly in construction, and not at all in type from the ancient written tongue. In the present number the proceedings of the Athenian Medical Society of last April are duly recorded, when it appears that a practical discussion took place upon Medical and Surgical topics of interest, including the subjects of tracheotomy, anasarca, bronchitis, pneumonia, and hæmorrhage from the womb, all of which had fallen under the notice of the speakers in their practice. The rest of the number is filled with articles, some original, and others selected, upon topics connected with medicine and the collateral sciences.

REVIEW OF BOOKS.

Notes on Hospitals. By Florence Nightingale. Third Edition. Enlarged and, for the most part, re-written. Pp. 187. London: Longman and Co. 1863.

It is almost a trite observation, that the mortality of diseases and injuries is quite as much dependent upon the arrangements of the hospitals into which the sick and wounded are received, as upon the Medical and Surgical appliances, strictly so called; and Miss Nightingale has conferred inestimable benefits upon the suffering classes, by her generous labours and writings in the cause of hospital improvement. It is quite true that, under good hygienic conditions, the worst diseases will often be improved or cured, and the results of the worst accidents, operations, and injuries will be favourable; while, under the opposite state of things, diseases, in themselves slight, will become serious, operations, apparently trifling, will be complicated with severe secondary results, and even new diseases will be engendered. Still, it appears to us, that in her laudable zeal to promote the object she has so much at heart, Miss Nightingale has somewhat overstated her case, especially in reference to the Metropolitan Hospitals. The apparently monstrous statement that in 24 London hospitals, the mortality is at the rate of nearly 91 per cent. of the cases admitted, while in county and other hospitals the mortality is only about 40 per cent., may be literally true, from the evidence of statistics; but it by no means proves the general insalubrity of the former, or the great superiority of the latter. It is well known that in the London Hospitals only the worst forms of diseases and injuries are admitted, while in the country hospitals the cases are much more miscellaneous; and even statistics have shown that, *cæteris paribus*, namely, by comparing together *the same classes of cases*, the disadvantage is by no means made to appear on the side of the metropolitan establishments.

Again, we do not entirely agree with Miss Nightingale in her returns of contagion and infection, nor can we admit that the mortality in the black hole of Calcutta (page 10), was in any way due to infection; it was, in fact, an instance of suffocation. It is indeed true that in badly constructed hospitals, and in badly arranged camps, and in armies and fleets under certain depressing moral and physical conditions, epidemic and contagious diseases will be generated and propagated to a frightful extent, but this fact does not prove that the same is the case in our London hospitals. The question of the spread of infectious diseases among patients affected with other ailments, and the question whether the former class of maladies should be treated in separate wards, are both of them very difficult problems, and we hardly think that Miss Nightingale is yet in a position to pronounce so decided an opinion as she has done on these very intricate subjects.

But, while thus differing in opinion from this most estimable lady and enlightened sanitarian upon these points, we can notice her book in general with unqualified praise, and recommend it most strongly to all those who may be interested, either from professional necessity or from philanthropic motives, in the construction and management of hospitals. Miss Nightingale has studied the subject, both theoretically and practically, in many parts of the world, and the book is illustrated by numerous diagrams, showing the merits or defects of a great number of existing hospitals. On the subjects of ventilation, cleanliness, moral management, and all other particulars, her remarks are characterised by extensive knowledge and enlightened views, mixed with no little shrewdness, and experience of human nature.

Three Hundred Consultations in Midwifery. By Robert Lee, M.D., F.R.S. Pp. 217. London: Churchill and Sons. 1864.

Dr. Robert Lee is so well known to the Profession as to need no introduction at our hands as an author or a practitioner. As a thoroughly practical man he has probably no superior in the department which he has chosen, while he has shown himself to be an unsparing opponent of certain theories and practices which have lately come into vogue, especially such as ovariotomy, the use of the speculum, the administration of chloroform in labour, the nature of the affections of the os uteri, and other such matters. Whatever may be thought of his views on these subjects, and however much his best friends may deplore the vehemence with which he has often advocated his own opinions, there can be no doubt of his enormous industry and of the success with which he has cultivated the obstetric art. Of the former quality his published works bear ample evidence, and his extensive consulting practice is an equally good test of the latter. The second edition of his 'Clinical Midwifery,' published in 1848, comprised the histories of five hundred and forty-five cases of Difficult, Preternatural, and Complicated Labour, and the volume now before us contains three hundred additional cases of a similar nature, arranged in the order of time in which they occurred, and spreading over a period of fifteen years. The cases are, of course, of a most varied description, and from the chronological order adopted, there is no attempt at classification or arrangement of any kind. Nevertheless, as a record of cases occurring to an obstetrical practitioner, they possess a very great value, especially to the beginner, while the most experienced adepts may learn many useful hints by a perusal of Dr. Lee's pages. His remarks are terse, short, and sensible, not unmarked by that boldness, and some might think, prejudice, which have characterised his career; and if names had been mentioned in connection with his cases, some of the observations might have led him into unpleasant correspondence with his contemporaries. As it is however, the parties whom he has met in consultation are not mentioned by

name, and, therefore, the book may be read with advantage, and without mixing up personal likings or dislikings with the doctrines or the practices which the author advocates or deprecates.

GENERAL CORRESPONDENCE.

MERCURY IN SYPHILIS.

To the Editor of the Medical Circular.

SIR,—Had Dr. Drysdale consulted Mr. Mill's work on 'Logic," with the view of learning, and not merely of quoting its contents, he could never have fallen into the egregious error of supposing that the passage cited by me was intended to prove ought in favour of, or against mercury. As he has failed to see this, I must refer him back to Mr. Mill's book, vol. 1, page 484, where he will find the following explanation.

"Let the subject of inquiry be the conditions of health and disease in the human body; or, (for greater simplicity) the conditions of recovery from a given disease; and, in order to narrow the question still more, let it be limited in the first instance to this one inquiry, is or is not some particular medicament (mercury for instance), a remedy for that disease."

In the passage quoted by me, (see MED. CIRC., Feb. 10th), Dr. Drysdale is at liberty to substitute chlorate of potash or any drug he likes for the word mercury, and the reasoning will be unchanged.

The question under discussion was, did a certain child die from mercurial treatment. That it died from such treatment, I say is incapable of proof, unless you can exclude from the case such death-producing causes, as bad air, bad food, and want of cleanliness.

Curiously enough, Dr. Drysdale states the point of his argument lies in this passage from Mill's "Logic," "and that he often will recover when it (mercury) is not administered, the other favourable influence being sufficiently powerful without it."

I must beg of Dr. Drysdale to explain, for I cannot see what possible bearing this has on the case of a child *who did take mercury*, but *did not recover*.

I must remind Dr. Drysdale that quibbling is not argument, and is not usually resorted to, except in a hopeless case.

I remain, &c.,

Maida Vale. R. S. SISSON, M.D.

MEDICAL SOCIETIES.

HARVEIAN SOCIETY, FEB. 4.

WM. ADAMS, ESQ., PRESIDENT, in the Chair.

Mr. J. ZACHARIAH LAURENCE exhibited two instruments which he had had constructed for the more accurate measurement of data, which it became necessary to determine in certain conditions of the eye.

1. A STRABISMOMETER.

This instrument was designed for the purpose of measuring the exact linear deviations of the eyes in cases of squint. It consisted of an ivory plate, corresponding in shape to the curve and general conformation of the lower eyelid. The middle line of the free border of the plate being marked O, gradations into lines and half lines towards each side (inner and outer respectively), were introduced. The centre of the lower border of the cornea of a normally placed eye, regarding a distinct object in an horizontal, median plane on the level of the eyes, corresponds to O; but in the case of a squinting eye to a gradation to the inner or outer side of O, according as the squint was convergent or divergent respectively. Mr. Laurence incidentally mentioned a convenient method of notation, which he adopted in these cases, designating by *plus* (+) gradations internal to O, and by *minus* (—) those external to O. Thus, a case of convergent strabismus of the right eye of $2\frac{1}{2}'''$ is briefly designated by $+ 2\frac{1}{2}'''$, one of divergent strabismus of $2\frac{1}{2}'''$ by $— 2\frac{1}{2}'''$.

2. A PUPILLOMETER (OR, PERHAPS MORE CORRECTLY, A COREOMETER).

This instrument is intended to measure the size of the pupil. It consists of a metallic plate graduated into lines, half and quarter lines, at one end of which is a fixed, vertical, knife-edged bar, and a second similar moveable bar, which can be separated or approximated to the former by a horizontal screw. In order to obviate the necessity of having two instruments (a right and left handed one), the metallic plate is graduated on both sides, so the horizontal screw is not stopped in its revolutions by coming into contact with the side of the nose. The inventor of the instrument stated that with it, one could easily and rapidly determine, with the greatest accuracy, the diameter of the pupil to a quarter of a line.

Mr. WM. ADAMS read a paper on

"TRANSVERSE FRACTURE OF THE PATELLA," IN ITS ORDINARY FORM AS GENERALLY PRODUCED BY MUSCULAR ACTION.

The author's attention had been first directed to the present subject in 1850, when he was engaged in describing the preparations in St. Thomas's Hospital for a new catalogue, and the series of specimens collected by Sir A. Cooper came especially under his examination.

Amongst these specimens was one described by Sir A. Cooper as an example of ligamentous union, in which the fragments were separated to the distance of five inches (No. 123 Museum Catalogue), and figured by Sir A. Cooper in his 'Treatise on Dislocations and Fractures of the Joints,' (plate 15, fig. 1), but the conclnsion which Mr. Adams came to after examining this specimen was, that no attempt at reparation had ever been made, and that it afforded a good illustration of non-union of transverse fracture of the patella. In this specimen the fragments were connected only by a thin expanded layer of fibrous tissue passing from the periosteal surface of the upper fragment to its connection with the lower fragment. The fractured surface of the upper fragment projected as a square or rectangular surface into the joint, and the connecting layer of fibrous tissue had no relation whatever with this fractured surface. This fact, the author considered, was fatal to the idea of the connecting tissue being an elongated condition of any fibrous connecting tissue structure formed between the fractured surfaces for the purpose of union, and Mr. Adams considered that it consisted only of the fascia and aponeurotic structures naturally passing over the surface of the patella in a thickened condition.

Mr. Adams exhibited this specimen, together with one of true ligamentous union of a transverse fracture of the patella, which he happened to meet with in a subject in the dissecting-room of St. Thomas's, now preserved in the Museum (Nos. 121 and 122 Mus. Cat.), to the Pathological Society in May, 1850, and in the 2nd vol. of the Trans. of this Society, these specimens are described, together with the conditions presented, by thirty-one other specimens of transverse fracture of the patella, preserved in the Museums of London.

The author considered that we must recognise three conditions as possibly resulting after transverse fracture of the patella—viz., 1, True bony union; 2, True ligamentous union; 3, Non-union, or ununited fracture.

In proof of the possibility of obtaining true bony union, specimens in the museums of Guy's and St. Bartholomew's Hospitals were referred to, together with others described by various authors.

With regard to the second method of repair, viz., true ligamentous union, the author observed that he only included in this series the specimens in which a mass of fibrous or ligamentous tissue passed directly between, and connected the fractured surfaces of, the upper and lower fragments. In such cases the separation of the fragments is generally from half an inch to an inch, the fragments being somewhat everted, more especially the lower one, so that the fractured

surfaces are directed, more or less, towards the skin; the gap between the fragments is therefore of a triangular form, the base being towards the skin, and the apex towards the joint. By a gradual elongation of the ligament, after the limb has been brought into use, the separation of the fragments may extend to an inch and a half, and in one specimen shown to the Pathological Society by Mr. Holthouse, this had extended to two inches and a half.

With regard to the third condition, above mentioned as the result of transverse fracture of the patella—viz., complete non-union or ununited fracture; the specimens included in this series are those in which there is an absence of fibrous or ligamentous tissue passing directly between and connecting the fractured surfaces, and in which the fragments of the patella are connected only by a thin, expanded, fibrous, and aponeurotic structure passing from the periosteal surface of one fragment to the periosteal surface of the other, and consisting essentially of the fascia and aponeurosis naturally passing over the joint in a thickened condition.

The relation of this aponeurotic structure to the separated fragments may be modified by its being folded in between, and becoming adherent to, the fractured surfaces, so that it may appear to pass from the centre of one fragment to the centre of the other or even between their articular edges; and this is generally produced by the folding in of the skin and fascia between the fragments; or by the eversion of the lower fragment the aponeurosis may become adherent to its fractured surface, so that it then appears to pass from the periosteal surface of the upper to the articular edge of the lower fragment.

In this condition described as ununited fracture, the separation of the fragments is not necessarily more considerable than in cases of true ligamentous union, and it may be even less, so that the separation is not to be depended upon as indicating the mode of union which must be judged of by the immobility of the fragments and general feeling of firmness, together with the absence of any depression between the fragments.

With respect to the relative frequency of true ligamentous union, and the condition described as ununited fracture, no reliable data exist, but Mr. Adams found that in thirty-one specimens which he examined in the six principal museums in London, fifteen were cases of ununited fracture, twelve were true ligamentous union, and four were obscure from being dried, &c.

In reference to the objects and methods of treatment with the view of obtaining either a true bony or a short ligamentous union, the indications are—1st. To subdue any inflammation which may follow the injury by cold lotions, &c.; 2nd. To approximate the fragments as soon after the injury as possible; and 3rdly. To retain the fragments in close apposition for a period sufficiently long to obtain either a true bony or a short ligamentous union.

After pointing out the causes of the inefficiency of the various appliances in general use, Mr. Adams stated his belief that the only apparatus capable of fulfilling all the indications in the treatment of transverse fracture of the patella was the instrument devised for this purpose by Malgaigne, and described by him in his 'Treatise on Fractures and Dislocations' in the year 1847. It consists essentially of four hooks, two of which are implanted in the superior border of the upper fragment of the patella, penetrating a little way into the tendon of the rectus muscle, and the other two hooks are implanted into the inferior border of the lower fragment, at the insertion of the ligamentous patellæ. The fragments are then drawn into apposition, and the hooks are fastened to each other by means of a screw working in a slide. This instrument has been used extensively in France, with the greatest success; serious inflammation does not appear to have been excited by it in any case, and there is ample testimony to prove that, as a general rule, the hooks can be borne without inconvenience or pain. In May, 1853, M. Malgaigne informed Mr. Adams that he had employed the hooks in eleven cases of transverse fracture of the patella with complete success.

The author stated that his own experience of the hooks had been limited to a single case, in which he applied them at the Great Northern Hospital two years ago. The case was one of ununited fracture of the patella of longstanding, and with wide separation of the fragments. Mr. Adams detached the connecting aponeurotic structure by subcutaneous section, and approximated the fragments by means of the hooks, which were borne for a fortnight without inconvenience, and the case was greatly improved.

In the 'Medical Times and Gazette' of Jan., 23, 1864, Mr. G. E. Pyle, house-surgeon of the Middlesex Hospital, has published the details of eight cases of transverse fracture of the patella, treated by Malgaigne's hooks in that Institution, and the results, as compared with eight other cases treated in the ordinary way, and also published were most satisfactory. In no case did the hooks give rise to local inflammation or injury to the joint.

Mr. CLEVELAND related the case of a healthy-looking lady, aged 50, who fractured both patellæ by slipping and trying to recover herself; the distance between the fragments was from one to two inches. The patient was laid on a mattress, with her shoulders raised and her feet elevated. The limbs were then placed on MacIntyre's splints, and an interval of ten days was allowed to elapse before bandages were applied. An appliance, sold by Weiss, called *Cooper's patella band*, consisting of two circular well-padded leather belts, made to lace one above the other below the knee, and drawn together by leather straps, were applied. In six weeks the splints were removed, and now, three months after the accident, she is able to walk about without any assistance. The lines of fracture are scarcely perceptible in either knee. Dr. Cleveland was inclined to ascribe part of this good result to the ten days rest of the parts before bandaging.

Mr. J. Z. LAURENCE mentioned a case where a gentleman had fractured his femur by muscular action.

Mr. CURGENVEN mentioned a case of double fracture of patella occurring in a stout gentleman, which had been most successfully treated by Mr. Adams, of the London Hospital, by bandages.

Dr. GRIFFITH, Mr. SEDGWICK, and Dr. DRYSDALE related successful cases of the treatment of fractured patella by bandages.

Mr. ALLINGHAM, in a letter to the president, related a case where a woman was seen by him at the Great Northern Hospital, in October last, both of whose patellæ had been fractured 30 years ago by her being thrown out of a cart. For this she lay for many months in St. Bartholomew's Hospital; and, when discharged, she wore an apparatus which anchylosed the knee, except when she sat down, when she drew a trigger. Lately, she had gone about with a common bandage. The distance between fragments was $6\frac{1}{2}''$ on right side, and $5\frac{3}{4}''$ on left. Her mode of progression was peculiar, but still she managed to get about with tolerable rapidity.

Mr. ADAMS, in reply, said, that all who had paid much attention to such cases had found how frequently the results of the ordinary operation were unsatisfactory. He had mentioned Malgaigne's method in 1847, in Dr. Druitt's surgery. This method gave, by far, the best chance of obtaining bony union, and there was no danger by using it of exciting inflammation in the joint and the pain caused by its application was insignificant.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEB. 9TH, 1864.

MR. PARTRIDGE, PRESIDENT.

GEORGE WILLIAM CALLENDER gave

SOME ACCOUNT OF THE AMPUTATIONS PERFORMED AT ST. BARTHOLOMEW'S HOSPITAL FROM THE FIRST OF JANUARY, 1853, TO THE FIRST OF OCTOBER, 1863.

These amputations are so arranged in a series of tables as to show for a number of consecutive years the totals of deaths and recoveries in male and female patients. The

operations comprise all the principal amputations, arranged as primary and secondary, and as amputations for disease. After some general remarks, certain deductions from the several tables are detailed.

Of 93 primary amputations, 78 recovered, and 15 died; thus 16·1 per cent. of all these amputations proved fatal, or 1 in 6·2; and if the age of the fatal cases, which averages 47 years, be taken into consideration, it appears, for children and for adults under 40, that an unfavourable result after these amputations is an exceptional occurrence.

The secondary amputations number 37, and of these 24 recovered and 13 died; so that 35·1 per cent., or 1 in 2·8 of all these operations, prove fatal.

Taking primary and secondary amputations together, 7·1 per cent. of those of the upper extremity, and 32·4 of those of the lower extremity, prove fatal; and 21·5 per cent., 1 in 46, of the total of traumatic amputations.

There are 228 amputations for disease or for malformations: 182 recovered, and 46 died, or 20·1 per cent. Of those performed at the upper extremity, 18·5 per cent died; whilst of those which involved the lower, 20·3 per cent. ended fatally.

It follows that of the total 358 amputations the ratio of mortality are; after all primary amputations, 16·1 per cent.; after all secondary, 35·1; after all amputations for disease, 20·1; after all amputations at the upper extremity, 10·8; after all those at the lower, 22·6; and after all amputations, 20·6 per cent.

Causes of death.—Old people are little able to resist the shock of the more severe amputations, the influence of age being most marked with primary operations. Females do not rally so easily as males after the severe shocks which precede and accompany primary amputations, nor after the depression consequent upon amputation at the thigh. The rate of mortality on the totals of cases is 18·9 per cent. for males, and 21·6 per cent. for females. The totals of deaths and of recoveries, as influenced by the age and sex of the patients, are shown in a separate table.

After primary amputations traumatic complications prove fatal at the rate of 40 per cent., and exhaustion at the rate of 20 per cent. of the total number of deaths.

After secondary amputations exhaustion is the chief cause of death, 38·4 per cent. sinking in this way; 23 per cent die from secondary hæmorrhage.

Of the total of traumatic amputations ending fatally, 28·5 per cent. sink from exhaustion, 25 per cent from traumatic complications, 21·4 per cent. from hæmorrhage, and 7·1 per cent. from pyæmia.

After amputations for disease ending fatally, exhaustion is the cause of death in 28·2 per cent.; pyæmia in 39·1 per cent.; and visceral complications in 15·2 per cent.

Taking the four chief causes of death after all amputations, we obtain the following rates of mortality in the totals of fatal cases:—

Amputations.	Hæmorrhage. Per cent.	Pyæmia. Per cent.	Exhaustion. Per cent.	Visceral Complication. Per cent.
Primary ...	20·0	—	20·0	6·6
Secondary ...	23·0	15·3	38·4	15·3
All traumatic	21·4	7·1	28·5	10·7
For disease...	4·3	39·1	28·2	15·2

Of the total 74 fatal cases, 24·3 per cent. die from exhaustion, 27 per cent. from pyæmia, 12·1 per cent. from hæmorrhage, 16·1 per cent. from visceral complications.

After giving the particulars of the cause of death in each fatal case, and the injury or the disease for which the operation was performed, the days in which 74 cases terminated fatally are shown in a tabular form. From this it appears that deaths from shock, or from other injuries, or from both combined, take place within the first twenty-four hours, and within forty-eight hours the deaths from recurrent hæmorrhage occur. Exhaustion is most fatal about the fourth day; secondary hæmorrhage is a cause of death from the fifth to the twelfth day; pyæmia from the seventh to the twenty-fourth.

Three cases of amputation are referred to, in which death was not accelerated by the operation, the patients dying on the 109th, the 102nd, and 93rd day respectively; and the paper concludes with an account of certain cases, and of certain sequences of fatal cases and recoveries, showing how necessary it is to mass together a considerable number of consecutive operations before we have a chance of arriving at tolerably just conclusions.

Mr. BRYANT, after remarking on the value of Mr. Callender's paper, said that he was surprised to find some startling difference in the results he had obtained, and in those he (Mr. Bryant) had deduced from a similar kind of analysis of the cases at Guy's Hospital. As regards numbers his and Mr. Callender's statistics were pretty much alike, but the rate of mortality was very different—in the former twenty per cent., in the latter twenty-five; when, for injuries, the difference was greater still, the mortality at Guy's being nearly double. In amputation for disease, however, it was the reverse. Mr. Bryant asked if it were possible that a difference of practice at the two hospitals could reconcile these differences? At Guy's, conservative surgery was carried to an extreme degree, and possibly too far. Then, perhaps, at St. Bartholomew's the practice might run a little towards the other extreme. He spoke, however, on this subject with great diffidence. Mr. Bryant then alluded to the very marked difference in the mortality after amputation of the upper extremity, in his and in Mr. Callender's series. Mr. Bryant then asked for the simple results as regards amputation of the thigh for disease of the knee-joint, as he wished to compare the mortality of this operation and that of excision of the knee-joint. The mortality of the latter was about one in five; whilst at Guy's and St. Georges that of amputation of the thigh was one in eight.

Mr. SOLLY suggested that, as regards the discrepancy in the gross results of amputation for traumatic injuries, the difference in severity of the injuries should be taken into account. At the Borough Hospitals there were many severe railway accidents.

Mr. SPENCER WELLS said that the surgeons of St. Bartholomew's and Guy's Hospitals might very justly cite the facts brought before the Society by Mr. Callender and Mr. Bryant, to prove that the mortality after amputations was very much less in these London hospitals than in the large hospitals of Paris and other continental cities. There the mortality ranged from forty to fifty per cent, while here it was twenty to twenty-five per cent. The surgeons of our hospitals might regard this comparison with great satisfaction, but it might still be true that the mortality here was excessive. He (Mr. Wells) believed that it was excessive, and that it ought to be and would be reduced. A mortality of one in four or five after amputations, including those of the forearm and leg, must be very much larger than it would be if hospital patients were placed more nearly in the condition of those who were operated on in private houses. It might be difficult or impossible to prove this by statistics, because any conclusions drawn from the few cases of amputation which any one surgeon could bring forward from his experience in naval or military or private practice would be met by some such curious facts as those just adduced by Mr. Callender. If he (Mr. Wells) or any one else were to say that of ten, or twenty, or thirty amputations, not one had died within six months after operation, the answer would be that such a result was as purely accidental as the fact that all the women who underwent amputation in St. Bartholomew's in one year died, and all in the next year recovered; and it would not be easy to reply to this argument, however firmly a surgeon might be convinced that his success was due to the care which he bestowed upon his patients, and that many of the causes of the excessive mortality in hospital practice might be avoided. A private patient clearly escaped any contagious influence from other patients in the same ward, and arrangement might perhaps be made to give greater protection against contagion to hospital patients. First year's students acting as dressers and dissecting on the same day might explain a portion of the avoidable mortality in hospitals from erysipelas and pyæmia. By attention to such matters as these, and by careful study of all those minor details in the mode of

operating and in after treatment, which, though apparently trivial, might assist in turning the scale one way or the other, it was well known that some important operations had been performed much more successfully in small than in large hospitals; and it was to be expected that similar care would also lead to greater success in all operations. The different sanitary condition of the hospitals of London and Paris was accompanied by a death rate of twenty to twenty-five per cent. in one city, and forty to fifty per cent. in the other. A great deal had been gained already, but a great deal more might be done; and when it is done, he (Mr. Wells) felt certain that the mortality after amputations would fall very far indeed below the present proportion of twenty per cent.

Mr. CALLENDER said that the great discrepancy Mr. Bryant had alluded to was accounted for by the difference in the ages of the patients in his own and in Mr. Bryant's series. Many of the traumatic cases were lads from printing offices in the neighbourhood, and the injuries were less severe than those from railway accidents. Then as regards the great mortality after amputation of the upper extremity, several of the cases were exceptional. Two died of erysipelas, and two were at death's door when the operation was done. He had not made an analysis as to the mortality from amputation above the knee, but would add a note on this point to his paper. In reference to the remarks by Mr. Spencer Wells, he said that, at St. Bartholomew's, great pains had been taken to improve the condition of the wards; and, moreover, a surgical registrar had been appointed, not merely to take notes of the cases of individual patients, but to watch the general health of the patients in the wards, to report upon any epidemics that might appear, and generally to supervise the hygienic arrangements, under the direction of the surgical staff.

In reply to the President, Mr. CALLENDER said that the gentleman appointed was not a student. He had been house-surgeon, and was highly qualified for the registrarship.

The PRESIDENT thought that, from the want of such registration, a vast amount of medical and surgical scientific material was utterly wasted. He should have thought, speaking in reference to Mr. Spencer Wells' suggestion, that dressers were not appointed from first year's students.

Mr. CALLENDER said they were not at St. Bartholomew's Hospital.

Mr. SPENCER WELLS said second and third year's students dissected as well as the first, and he had not heard of any restriction upon dressing by students who were dissecting.

J. W. HULKE, Esq., F.R.C.S., presented a

MEMORANDUM OF A CASE OF STRANGULATED FEMORAL HERNIA, WHERE, ON A FORMER OCCASION, THE NECK HAD BEEN TORN FROM THE BODY OF THE SAC IN THE TAXIS, AND THE EXTRUDING BOWEL HAD FORMED A LARGE POUCH OUTSIDE THE PERITONEUM.

A woman, aged seventy, was admitted into the Middlesex Hospital on Oct. 12th, 1863, with a strangulated femoral hernia of moderate size. The strangulation was relieved by herniotomy, but the bowel could not be fairly put back into the belly. Death occurred about seventeen hours after the operation. At the post-mortem examination, the body of the sac was found *in situ*. The femoral ring opened into a large subperitoneal pouch, which contained eight feet of gut, and communicated by a round aperture, the original neck of the sac, with the peritoneal cavity.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

FEBRUARY 15.

INSANE PRISONERS ACT AMENDMENT BILL.

In the House of Commons, on the order for the second reading of this bill,

Mr. G. HARDY adverted to the case of Townley to show what amendments of the law were, in his opinion, required, and pointed out in what respects he thought the bill did not provide an adequate remedy, especially with reference to prisoners under sentence of death; suggesting, at the same time, certain alterations in a future stage of the bill. He noticed the extraordinary confusion and conflict of opinions in Townley's case.

Mr. MACDONOGH reiterated his argument that the words "it shall be lawful" in the Act the 3rd and 4th of Victoria were not imperative, but permissive, and objected that this Bill was founded upon a wrong principle; that it should be declaratory only of the construction to be put upon the words of the particular Act.

Sir C. O'LOGHLEN did not oppose the second reading of the Bill, which he thought should not be confined to England, and he explained the state of the law in Ireland in this particular, insisting that there should be uniformity in the law in England, Scotland, and Ireland.

Mr. SCOURFIELD thought there was not one of the provisions in the Bill which was objectionable, though some might not go far enough. Every step in the measure, however, seemed to him to be in the right direction.

Mr. W. D. SEYMOUR asked how it was proposed to deal under the Bill with cases like that of Townley.

Mr. HUNT called attention to and reiterated some of the objections urged by Mr. Hardy. He thought the Bill, so far as it went, would not place the law in a satisfactory state.

Lord ENFIELD suggested objections to certain provisions of the Bill.

Mr. M. SMITH, having considered the defects of the law and the provisions of the Bill, had come to the same conclusion as Mr. Hardy. He urged that the question of the supervening insanity of a prisoner should be determined by the old constitutional form of inquiry by a jury.

Remarks were made upon various provisions and details of the Bill and suggestions offered by Mr. Evans, Sir G. Bowyer, Sir F. Goldsmid, and Sir W. Jolliffe.

Sir. F. KELLY, after reviewing the state of the common and statute laws upon this subject, and showing the imperfections of the Act 3rd and 4th Victoria, pointed out what he regarded as defects in the Bill, which provided, he said, no remedy for an important error in that Act. It made no distinction between one kind of unsoundness of mind which exempts an offender from responsibility for his actions, and another kind which leaves him responsible. Referring to the case of Townley he insisted upon the unconstitutional character of the jurisdiction exercised by the Secretary of State.

After some observations by Mr. M'Mahon and Alderman Rose,

Sir G. GREY discussed the suggestions which had been thrown out in the course of the debate (as to some of which, he said, he should not express a decided opinion), especially the main suggestion of Mr. Hardy, that cases of prisoners udder a capital sentence should be dealt with in a separate manner. There was nothing in the Bill, he said, to prevent the capital sentence in a case similar to Townley's being legally carried into execution. He remarked, with reference to that case, that the inquiry after conviction was no revision of the verdict of the jury, but was consequent upon alleged insanity supervening after conviction. Admitting that the law respecting criminal lunatics in Scotland and Ireland was not satisfactory, he stated reasons why it was not expedient to extend the Bill to those parts of the United Kingdom.

The Bill was then read a second time.

LEGAL INTELLIGENCE.

COUNTY COURT, THAME, JANUARY 30TH.

Before J. B. PARRY, Esq.

WALKER *v.* GUARDIANS OF THE THAME UNION.

This was a claim of 3*l.* 10s. for Medical attendance in seven cases of childbirth. The plaintiff said—I reside at

Brill, and am a Medical district officer in the Thame Union. In that capacity I am called on to attend cases of midwifery. I have done so in accordance with instructions issued by the Poor-law Commissioners. I have now been kept out of my claim for three-quarters of a year: my charge is 10s. per case, contract with the board of guardians, and as their Medical officer I am bound to attend cases upon receiving an order to that effect from an overseer. Brill, with a population of 1400 inhabitants, has no resident midwife, and the relieving officer lives at Thame, a distance of seven miles. I was told by the board that I had no claim upon them. If I have no claim upon them, am I bound to attend to the orders of overseers? Mr. Walker read two articles in which it was stated that Medical officers must attend cases of childbirth upon receipt of an order from a guardian, relieving officer, or overseer.

The JUDGE—The question is whether an overseer is a proper person to give an order in cases of midwifery.

The defendant's attorney referred his Honour to the latter part of Article 48, where it stated that orders issued by overseers must be in cases of sudden and urgent necessity.

The JUDGE—What I should term cases of sudden and urgent necessity would be supposing that a woman was taken ill with childbirth on the road or in a field. I should then have no difficulty in coming to a conclusion for the plaintiff. Are these cases so? The question is who is to pay you. I am clearly of opinion that an ordinary case of midwifery is not one of sudden and urgent necessity, and therefore not one for which the guardians would be liable to pay. The board are not in this instance guardians of their own purse, but of the public purse. Judgment will be for defendant. Plaintiff is nonsuited.

After some conversation the overseers were called, and Mr. HOME, in reply to plaintiff, said, as overseer he was applied to for the orders, and he considered they were cases of necessity. Once or twice the births took place in a few minutes after Mr. Walker arrived there. He (the overseer) considered they were all cases requiring immediate assistance; that some of the poor had not means to pay; and in one or two instances the parties for whom the orders were given were really in distressed circumstances.

Mr. WALKER applied that the case might be adjourned to get the advice of counsel.

The JUDGE, however, declined to grant an adjournment, observing that he sat there to act upon the matter to the best of his knowledge, and that judgment would be given for the defendants. If it were not so Brill would soon become a lying-in district; persons would go there in cases of childbirth, to have attendance free. Upon that principle any one by giving notice to the overseer, at the last moment, would be able to get an order, and the expense would be charged to the Union.

[We agree with several of our contemporaries in thinking that this decision is contrary to law, as it certainly is to justice and humanity.—ED. MED. CIRCULAR.]

Births, Marriages, and Deaths.

BIRTHS.

BARNES.—On the 12th inst., at Pembroke place, Liverpool, the wife of J. H. Barnes, M.R.C.S.E., of a son.

BENNETT.—On the 31st ult., at Potter street, Worksop, the wife of E. Bennett, M.R.C.S., of a daughter.

BISHOP.—On the 9th inst., at Tunbridge, the wife of H. Bishop, M.R.C.S.E., of a son.

CORFE.—On the 13th inst., at Nottingham terrace, Regent's-park, the wife of G. Corfe, M.D., of a daughter.

CREWE.—On the 24th of Dec., at Bhaugulpore, Bengal, the wife of A. G. Crewe, Civil Surgeon, of a son.

DIVER.—On the 5th inst., at Yately, the wife of E. Diver, M.D., of a daughter.

HASSE.—On the 11th inst., at Illenau, Grand Duchy of Baden, the wife of J. P. Hasse, M.D., of a son.

MURPHY.—On the 1st inst., at Dingle, Co. Kerry, the wife of P. Murphy, M.D., of a son.

PARSONS.—On the 9th inst., the wife of W. D. Parsons, M.R.C.S.E., of a daughter.

MARRIAGES.

CADGE—QUAIN.—On the 9th inst., at St. Marylebone Church, W. Cadge, F.R.C.S.E., of Norwich, to Mary, daughter of the late John Quain, Esq., of Mallow, Ireland.

CHISHOLM—GARDNER.—On the 4th inst., at St. John's Church, Paddington, E. Chisholm, M.R.C.S.E., late of Calder house, Newtown, Sydney, to Emily, daughter of W. Gardner, Esq., of Dover.

MAYBURY—CRAWSHAY.—On the 16th inst., at St. Matthias's Church, Richmond hill, Augustus Kingston Maybury, M.D., of Richmond, Surrey, to Julia, youngest daughter of the late Richard Crawshay, Esq., of Ottershow park.

MEYHOFFER—ELTON.—On the 8th inst., at Nice, J. J. Meyhoffer, M.D., of Berne, Switzerland, to Mary Anne, daughter of the late E. W. Elton, Esq., of London.

M'NAB—HUMBER.—On the 4th inst., at Preston, R. M'Nab, M.D., Surgeon 53rd Regiment, to Ellenor Esther, daughter of J. Humber, Esq.

SECCOMB—WILCOCKS.—On the 6th inst., at St. James's Devonport, T. Seccomb, M.R.C.S.E., Surgeon H.M's Ship "Cambridge," to Julia, daughter of J. B. Wilcocks, Esq., of Stoke Cottage, near Plymouth.

SMYLY—PLUNKET.—On the 1st inst., at Dublin, P. C. Smyly, M.D., eldest son of the late J. Smyly, F.R.C.S.I., to Selina Maria, daughter of the Hon. J. Plunket, of Sherrington, Bray.

DEATHS.

BRIERLY.—On the 7th ult., at Davenport House, Staleybridge, John Brierly, M.R.C.S.E., aged 55.

BULL.—On the 30th ult., at Cittadella, Joshua Bull, M.D.

CORY.—On the 17th of Dec., at Bridport, suddenly, S. S. Cory, M.R.C.S., one of the Coroners for the County of Dorset, and J.P.

COWCHER.—On the 31st ult., E. Cowcher, M.R.C.S.E., of Abingdon, one of the Coroners for the County of Berks, aged 77.

GARDNER.—On the 27th of Dec., at Toronto, Canada West, C. Gardner, M.D., aged 40.

GRANGER.—On the 4th ult., at Exeter, F. Granger, M.B., Consulting Physician to the Devon and Exeter Hospital, aged 73.

GUNN.—On the 8th inst., at Edinburgh, John Gunn, L.R.C.S.Ed., Surgeon, R.N., Jan. 26th, 1855.

JONES.—On the 3rd inst., W. Vaughan Jones, M.R.C.S.E., of Festiniog, Merionethshire, aged 41.

LAWSON.—On the 11th ult., at Horbury crescent, Notting hill, Joseph A. Lawson, M.D., Deputy Inspector-General of Hospitals Army, aged 57.

O'BRIEN.—On the 2nd of Dec. G. W. O'Brien, M.D., of Bellevue, Ennis.

PARTRIDGE.—On the 6th inst., W. Strowd Partridge, L.SA., of High street, Bordesley, Birmingham, aged 43.

RIND.—On the 17th of Dec., at Sangor, Central India, M. M'N. Rind, Deputy Inspector-General of Hospitals, Sangor Circle, Bengal.

ROSS.—On the 12th inst., at Pembridge crescent, Bayswater, Dr. A. Ross, late of the H.E.I.Co's Service, aged 67.

SHORLAND.—On the 18th of Dec., T. Shorland, L.S.A., of High street, Alderney, Admiralty Surgeon and Agent.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on the 15th inst., the following gentleman, having undergone the necessary examination, was duly admitted a member of the College:—Scholes Butler Birch, M.D. St. Andrew's, Gore Lodge, Upper Kensington Gore.

At the same meeting, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—Henry Brietzcke, Deptford; Charles Cameron, H. M. Bengal Army; William Gill, Truro, Cornwall; Duncan Maclachlan Maclure, 16 Harley street; Arthur George Mickley, Buntingford; Cosby William Morgan, Newcastle, New South Wales; Henry Hitchcock Parry, Allington, Devizes; George Frederick Thomas, Taranaki, New Zealand; Kenrick Henry Bold Williams, Llansaintffraid, Conway.

The following gentlemen were reported by the Examiners to have passed the first part of the Professional Examination:—Samuel Freeman Bagnell, King's College; William Bell, King's College; Frederick John Burge, King's College; Thomas Collier, Guy's Hospital; Benjamin Lamb Powne, St. Bartholomew's; George William Rigden, University College.

DEATH OF DR. ELFINGER.—Dr. Elfinger, so celebrated in Germany as a painter of pathological objects, died suddenly last month in Vienna from an attack of hæmoptysis, having been only an hour before engaged in taking some laryngoscopic views for Dr. Türk, in the Vienna General Hospital. Our readers must be well aware of his powers as a faithful pathological artist, through the plates of skin diseases he has brought out in co-operation with Hebra, several of which have been republished by the New Sydenham Society.

THE PROPOSED SPANISH MEDICAL CONGRESS.—The period for the assembling of this congress at Madrid is fixed for September 24 next. It will be held during six days, the two first being devoted to verbal or written communications, and the others to discussions. Foreigners must speak either in Spanish or French. A written communication must not occupy more than twenty minutes in duration, and a verbal one-half that time. In the discussion, the speakers are to be allowed a quarter of an hour, and must only address the congress once upon the same subject. The following are the questions proposed for discussion:—1. The importance of quarantine and lazarettos. 2. The value of surgery in the treatment of cancer. 3. The causes of pulmonary consumption, and the means of preventing or diminishing its ravages. 4. The criterium of moral liberty in the perpetration of crime. Any one possessed of a diploma in Medicine or Surgery or the accessory sciences may take part in the congress on the subscription of 60 reals (12s. 6d.), for which a copy of the proceedings will be furnished. All communications upon the subject are to be addressed, post free, to Dr. De Lugue, 8 Calle Atochia, Madrid.

INSANE PRISONERS.—Sir George Grey's bill provided that the inquiry by two or more justices into the insanity of a prisoner is to be conducted by visiting justices, "if the prison is one to which visiting justices are appointed." Also, instead of the enactment, that the two justices are to inquire "with the aid of" two Medical men, this bill directs the two justices "to call to their assistance" two Medical men, thus making the justices responsible for the selection of the Medical men. The Medical men are to be persons registered under the Medical Registration Act. On receiving from the justices and the Medical men a certificate that a prisoner is insane, the Secretary of State "may, if he shall think fit," direct that the prisoner be removed to a lunatic asylum. In regard to the very important subject of the release of a prisoner who has been insane, the bill proposes that if two registered Medical men shall "duly certify" to the Secretary of State that the prisoner "is sane," the Secretary of State shall be "authorised" to direct that he be discharged out of custody if his sentence has expired by efflux of time.

AUTHORITY OF MILITARY COMMANDERS OVER GENERAL HOSPITALS IN AMERICA.—The case of Assistant-Surgeon Warren Webster, U.S.A., tried for disobedience and conduct prejudicial to military discipline, embraces the following facts:—General Canby, commanding the city and harbour of New York, ordered General Brown, commanding the post at Fort Schuyler, to arrest and send to Governor's Island a soldier represented to be at that post. The man being not at the post, but in the McDougall General Hospital, General Brown ordered Dr. Webster of the regular service, in charge of hospital, to arrest the soldier and send him as before mentioned. The man was at the time confined to his ward by the results of a severe surgical operation just performed, and could not be removed with safety. The surgeon in charge reported to Gen. Brown that since General Hospitals were under the control of the Surgeon-General he considered it his duty to remove patients only when orders came through the Medical Director; and for this report he was put on trial. Orders heretofore given had been through the Medical Director or the Surgeon-General. The court-martial found Surgeon Webster guilty, and sentenced him to "be confined to the limits of his post for six months, and to be reprimanded in General orders by the general commanding the department." General Dix modified the sentence, confining him to his post for sixty days. This case raises some nice points affecting the position of Surgeons in charge of hospitals.—'American Medical Times.'

SURGEON-GENERAL HAMMOND OF THE U.S. ARMY.—We are glad to learn that the severe injury which this gentleman received by a fall at Nashville, is not likely to produce permanent ill-effects. At first he was deprived of the use of his lower limbs, but the most serious symptom has in some measure disappeared. It is now confidently anticipated that his recovery will finally be complete.—'American Medical Times.'

ARMY MEDICAL DEPARTMENT.—The Director-General of the Army Medical Department, presents his compliments to the Editor of the MEDICAL CIRCULAR, and begs to enclose a list of the candidates who were successful at the competitive Examination in August last, and who have passed through a course at the Army Medical School.

6 Whitehall yard, London,

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, FEB. 24.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Gulstonian Lectures: Dr. Markham, "On the Uses of Bloodletting in Disease;" Junior Medical Society of London, 8 p.m.; Meeting at the Whittington Club, Arundel street, Strand: Mr. J. Warrington Haward, "On the Treatment of Hernia.

THURSDAY, FEB. 25.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Tyndall, "On Experimental Optics," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

FRIDAY, FEB. 26.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Gulstonian Lectures: Dr. Markham, "On the Uses of Bloodletting in Disease;" Royal Institution, 8 p.m.—J. Prestwich, Esq., "On the Quarternary Flint Implements of Abbeville, &c."

SATURDAY, FEB. 27.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, FEB. 29.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAR. 1.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Phthisis and the Stethoscope: or the Physical Signs of Consumption. By Richard Payne Cotton, M.D., &c. Third Edition. London: John Churchill and Son.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

THE ARMY MEDICAL DEPARTMENT.—The list has been received.

A CANDIDATE.—Certainly.

Dr. SISSON'S letter is inserted.

THE HARVEIAN SOCIETY.—The Report has been received.

JOHN LACEY, whose case was reported on page 308 of the CIRCULAR of June 3rd, 1863, appeared before the Medical Council on 10th July following, and having satisfied them that the allegations against him were not true, they ordered his name to be entered upon the 'Medical Register,' which was accordingly done forthwith.

ANTI-HUMBUG.—We are willing to allow the subject to be discussed in our columns, but we must be excused at present from taking one side or other in the controversy.

Dr. M.—The question is entirely a private one, and should be settled by referring it to a mutual friend.

A TRADESMAN.—There is no doubt that the adulteration alluded to is practised to a very considerable extent, but unfortunately the chemical analysis of many organic bodies is beset with great difficulties, and the results are very uncertain.

A STUDENT.—The skin disease in question is now ascertained to be caused by the presence of a cryptogamic plant, of the nature of a fungus.

A DRUGGIST.—Pyroxylin and pyroxylic spirit have no relation to one another, except in name. The first is the scientific name given to gun-cotton, the second is the hydrated oxide of methyle, popularly, but erroneously, called naphtha.

A UNION SURGEON.—We have expressed our opinion, in another part of our Journal, that the judgment was wrong.

Dr. B.—The question having now been settled in the manner originally proposed, it is better to allow the subject to drop.

A SURGEON, *Birmingham.*—We have received the newspaper, and have mentioned the case.

Mr. MCGREEVY, *Lurgan.*—Contribution received, and is under consideration.

HERTS.—We do not agree with the concluding part of the note, and we must decline to insert the communication.

THE MANAGER OF THE ALEXANDRA PARK.—The Report has been received.

Saint Saviour's Union.—District MEDICAL OFFICER.—The Guardians of the above Union hereby give notice, that they will, on Thursday, the 3rd day of March next, at Three o'clock in the afternoon, hold a meeting at the Board Room of the said Union, situate in John street West, Blackfriars road, in the county of Surrey, for the purpose of APPOINTING a duly qualified MEDICAL OFFICER for the St. Saviour's District of the said Union. The salary will be 75*l.* per annum, with extra Medical fees for Midwifery and Surgical Cases, as provided by the Orders of the Poor Law Board.

The gentleman appointed will also have the contract for Vaccination, and will have to reside in the District.

Candidates are requested to send in applications, with Testimonials and particulars of their qualifications, to my office, as above, on or before the 2nd day of March next. Canvassing the Guardians is strictly prohibited.

Dated this 18th day of February, 1864.

JAMES J. BLAKE, Clerk to the Guardians.

Emperor Life and Fire Assurance SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

Norwich Union Fire and Life Offices. NOTICE OF REMOVAL.

The Directors HEREBY GIVE NOTICE, that in consequence of the immediate extension of the London, Chatham, and Dover Railway they have vacated their Offices, No. 6 Crescent, New Bridge street, and REMOVED to their NEW PREMISES, No. 29 FLEET STREET, E.C.

February 4, 1864.

Coxeter's Illustrated Catalogue, much enlarged, price 1s. 6d., including postage.

Mr. Henry Thompson's Dilator for Gradual Distension of Stricture.

COXETER, 23 & 24 Grafton street East, London, W.C.

Vaccination. Liquid Vaccine LYMPH, in purity and source guaranteed, in Capillary Glass Tubes, hermetically sealed, which preserves it for any period, supplied to the Profession by Mr. FAULKNER, M.R.C.S., Operative Chemist, &c., Endell street, Long acre, London, W.C. Three Tubes sent by return of post, with instructions, on receipt of 30 stamps.

Hedges & Butler, Wine Merchants, &c., recommend and GUARANTEE the following WINES;

Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s.	and 30s.	per dozen.
Good Hock	30s.	,, 36s.	,,
Sparkling Epernay Champagne, 36s.,	42s.	,, 48s.	,,
Good Dinner Sherry	24s.	,, 30s.	,,
Port	24s., 30s.	,, 36s.	,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820	at 120s	per dozen.
Vintage 1834	,, 108s.	,,
Vintage 1840	,, 84s.	,,
Vintage 1847	,, 72s.	,,

all of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s.; superior Sherry, 36s., 42s. 48s.; Clarets of choice growths, 36s., 42s., 48s., 60s., 72s., 84s.: Hochheimer, Marcobrunner, Rudesheimer, Steinberg, Liebfraumilch, 60s.; Johannesberger and Steinberger, 72s., 84s., to 120s.; Braunenberger, Grunhausen, and Scharzberg, 48s., to 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontignac, Vermuth, Constantia, Lachrymæ Christi, Imperial Tokay, and other rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; very choice Cognac, vintage 1805 (which gained the first-class gold medal at the Paris Exhibition of 1855), 144s. per dozen. Foreign Liquers of every description. On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,

London, 155 Regent street, W.; and 30 King's road, Brighton.

(ORIGINALLY ESTABLISHED 1667.)

Fine Old Port, Twelve Years in Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clarets, 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints; 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts; 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

Quinine.—The Medical Profession —the LANCET—Dr. Hassall, and others recommend "Waters' Quinine Wine" as an excellent and simple stimulant. Manufactured only by ROBERT WATERS, 2 Martin's lane, Cannon street, London, E.C. Sold by Grocers, Italian Warehouse men, and others, at 30s. a dozen.

Wholesale Agent, E. Lewis & Co., Worceste .

The Medical Circular.

CLINICAL LECTURES.

MIDDLESEX HOSPITAL.

ABSTRACT OF A LECTURE

ON CERTAIN DISPLACEMENTS OF THE UTERUS,

DELIVERED BY

DR. HALL DAVIS,

In the Theatre of the Middlesex Hospital.

Continued from page 132.)

Dr. Wm. Hunter, in his remarks on Mr. Wall's case, observes :—

"After the case was suspected, from the suppression of urine, and then certainly known by the examination with the finger, both in the vagina and rectum, the urine was first completely drawn off by the catheter: then a sufficiently stimulating clyster was thrown up; and after the bowels were well emptied, it was found easy to replace the uterus. In one instance, the uterus of itself recovered its natural position immediately after the above-mentioned evacuations had taken place. In another case, there were several relapses before the uterus grew so large that it could no longer fall back."

Dr. Francis Ramsbotham cites eight cases in which the womb righted itself, the only means adopted for the reduction being the keeping of the bladder from any, even the slightest, degree of distension. In addition to this plan, recommended by Dr. Ramsbotham, Drs. Blundell and Duncan advise that the patient be placed on her elbows and knees for some time each day.

We should strongly enjoin upon our patient to sit as little as possible, and to preserve, as much as she can, the horizontal pronate position.

But the case may assume a more formidable appearance than that we have been just describing, and we may be called upon to bleed from the arm, if there be considerable swelling, irritation, or inflammation; also to foment well the external parts, and to make use of hip-baths before we endeavour to obtain a reduction of the displaced organ.

Some seek to effect reduction by means of the *finger* in the rectum, but with a piece of cane to the end of which a small portion of sponge is attached we are better able to reach the tumour, and can exercise more decided pressure. It has been proposed that the entire of the hand should be passed into the bowel, when the finger or fingers are not sufficient, but this is very questionable treatment, produces excessive pain, and tends rather to evil than to good results.

Dr. Churchill considers that we might be justified in using a pair of hooked forceps for the purpose of seizing the cervix, in order to bring it down, while we are tilting upwards and forwards the fundus uteri.

Dugès introduces a sound into the bladder, and with it depresses the cervix uteri, at the same time that the fundus is elevated into its natural situation.

Dr. Halpin, of Cavan, in Ireland, has practised, and with success, the introducing of a bladder into the vagina and its subsequent inflation, so as literally to force the displaced womb out of its unnatural into its accustomed berth. The following are Mr. Halpin's own words: "It suddenly occurred to me that, with the assistance of the bladder, I should be able to inflate the pelvis and thus raise its contents into the abdomen.

"We acted on this suggestion; I attached a small bladder to the tube of a stomach-pump, with an air-tight piston, and having immersed it for a few moments in warm water to bring it to the heat of the body, I introduced it empty into the vagina, between the fundus of the uterus and the rectum. Retaining it within the vagina by holding my hand firmly across its orifice, it was inflated slowly and steadily. After a time she complained of tension, or bursting, but no pain. We then ceased throwing air into the bladder, allowing what was in already to remain, keeping up, as it did, a steady, equal, well-directed pressure on the tumour. After the expiration of five minutes, we threw more air into the bladder, when the patient exclaimed slowly, 'Oh! now you are forcing something up to my stomach!' I retained the bladder sometime longer in its situation, and then, previous to withdrawing it, permitting the escape of some air, I introduced my finger, and had the satisfaction of finding that the tumour was no longer in the pelvis, and that the os uteri lay within reach of my finger, pointing downwards and backwards. I then, and not till then, removed the apparatus."

M. Favrot advises the passage of an india-rubber bottle into the rectum, and its subsequent injection in the same manner as mentioned by Mr. Halpin; and Dr. Churchill has successfully employed the bottle, passing it, however, not into the rectum, but into the vagina.

Dr. Bond, in the 'American Journal of Medical Sciences' for April, 1849, describes an instrument which he had constructed for restoring the womb when it has been retroverted: there are two branches, both of them being curved, and terminating in a button-shaped extremity, the rectal of which is longer than that intended to pass into the vagina; this latter branch can, however, at pleasure be shortened or lengthened. The object sought to be obtained is pressure on the fundus by the rectal and upon the os uteri by the vaginal branch.

When pyrexia and irritation supervene they must be treated accordingly.

Of cases of early pregnancy, coexistent with the retroversion, Dr. Blundell writes:—"Where the catheter could not be introduced nor the rectum emptied, I should feel myself inclined to consider the propriety of tapping the uterus, which might perhaps be found, on the whole, to be as desirable an operation as tapping the bladder, or dividing the symphysis pubis. I should not like a great trocar and canula, as if I were going to tap for ascites: I should prefer an instrument of very small size, by which I could perform a sort of acupuncturation. A good deal of the liquor Amnii, might be drawn off.

If the uterus were thus evacuated of the liquor Amnii, there would immediately be a considerable reduction of its bulk, and, perhaps, at length an expulsion of the ovum.

The womb might be tapped either from the vagina or the rectum; but vaginal tapping would, I conceive be preferable.

Dr. William Hunter was the original deviser of the plan just mentioned as being strongly advised by Dr. Blundell.

Callisen has even gone so far as to advise gastrotomy, in order to admit the hand to seize directly the uterus and restore it to its wonted situation. But this is, indeed, heroic treatment, and certainly by no means preferable to tapping.

Others have advised the section of the symphysis pubis on the hypothesis that more space would be allowed for the return of the dislocated viscus.

Anteversion is the very reverse of the lesion, which we have been describing, the fundus being thrown forwards while the os looks more directly backwards than in the natural condition of the parts; the entire cervix is made to project unusually backwards.

Owing to the manner in which the fundus lies so as to be easily felt through the bladder, the case has been mistaken for one of calculus, the patient was submitted to an operation for the removal of the supposed stone, death resulted

the post-mortem showed no stone, but revealed the anteversion. (See Capuron : 'Mal. des Femmes.')

Symptoms are not by any means so well marked as in retroversion or retro-flexion, and as a natural consequence the distress is not so great. There may be some irregularity of the menstrual functions, and some amount of leucorrhœa may be present, as well as pains in the perinæum, or uneasiness, not amounting to pain, all over the pelvic region, and a dragging sensation about the loins; constipation, if it occur, will be not the obstinate form attendant upon displacement of the womb backwards, amounting rather to a difficulty in defæcation than to any actual constipation; retention of urine is rare, but may be produced by the pressure exercised upon the neck of the bladder or upon the urethra; ordinarily, however, the symptoms of this anterior displacement are not well marked.

Causes.—The uterus may be top-heavy, and then a blow, a fall, a sudden leap or start may dislocate the organ. The causes of the top-heaviness will be the same as obtain in retroversion and retroflexion, but somewhat altered as to the site of the uterine walls.

Relaxation of the uterine ligaments is a predisposing cause.

Early pregnancy, that is, before the woman has quickened, may effect the displacement by giving to the fundus uteri an unwonted heaviness.

It may happen that on the emptying of the bladder a sudden and forcible expulsive effort is made, and the lesion thus occasioned. This is most likely to obtain in delicate women, in whom the uterine ligaments and supports have become relaxed, or in those in whom the same kind of relaxation exists as a sequence of parturiency.

Accumulations of fæces in the larger intestines or, again, a severe diarrhœa, though two diametric conditions, are assigned as causes.

Dr. West saw a patient, to whom the accident occurred probably by the straining efforts she used in turning a mangle; she was the mother of four children; another case, in which there was hæmorrhage; great epigastric pain supervened; an examination demonstrated the existence of anteversion.

The fundus usually deviates to one or other side; this has been supposed by some to be due to gaseous or fæculent accumulations in the sigmoid flexure of the colon, or in the upper part of the rectum; or to the ligaments and supports on one side being shorter than on the other, or to some irregularity in the original bilateral development of the uterus, one half being more weighty than the other.

Treatment.—A cure may be effected by means of different kinds of pessaries, and by the patient maintaining the horizontal supine posture.

Dr. Simpson and M. Valliex employ stem pessaries; but these are open to objection, owing to the irritation produced in the womb, or to the inflammation excited in it by their presence in its cavity.

Nauche recommends a hollow pessary, so that the neck of the womb may rest in it, and be thus supported.

In some instances the displacement will be reduced by merely filling the bladder at the same time that the rectum be emptied.

In order to restore, not the uterus alone, but also the other parts in this region, to their normal vigour, we should prescribe the frequent use in the day of cold sponging and of cold vaginal injections; and they will be found valuable adjuvants in our treatment, both before and subsequent to our restoring the affected organ to its natural position.

DR. THOMAS E. HEADLAM, of Newcastle-upon-Tyne, who occupied a prominent position in his native town as a physician and a member of the corporation, died on the 18th inst., at the advanced age of eighty six. He was an active member of the local parliament, and a strenuous supporter of the Whig interest. His name is not associated with any medical discoveries or writings; but he was highly respected, and is deeply lamented.

ORIGINAL COMMUNICATIONS.

Clinical Observations ON CHLOROFORM,

WITH SPECIAL REFERENCE TO PUERPERAL CONVULSIONS, AND A NEW DISTINCTION OF THESE CASES.

BY CHARLES KIDD, M.D., M.R.C.S.

While studying recently the general phenomena of chloroform administration in midwifery, more especially the stage of convulsive excitement that usually precedes the stage of deep narcotism, attention has been drawn particularly to a physiological fact of some importance, viz., that black venous blood in muscles, or pressure exerted on the *venæ cavæ*, always increases this condition of chloroform excitement; in a word, that black blood acts as a stimulus to muscles, and most probably such pressure as that of a gravid uterus on the cavæ and other venous vessels in the abdomen in some patients, may be one of the causes, or more correctly, the immediate or chief cause of one of the forms of puerperal convulsions; very possibly that form said to be so much relieved by bleeding from the arm, where this back tide or *remora* of venous blood is taken directly out of the system. Of the fact, physiologically, there is no doubt that such convulsion and black blood in muscles from impediment to respiration, are almost inseparable from chloroform administration. The diaphragm, as one of these muscles (and an important one), is not free from these convulsive actions; the cardiac orifice of the stomach, too, which passes immediately through a foramen of this muscle, and is always, like this muscle, intensely sensitive to such pressure or convulsion (though the pyloric end is not), both re-act, hence the violent vomiting so often under chloroform, or vomiting and hiccup occasionally in ordinary labour cases, where the labour is rather slow, hence, probably, the misery of "sea sickness" from the up and down, dragging of the cardiac orifice or end of the stomach in the foramen of the diaphragm, and hence, probably, the "morning sickness" of pregnancy, the enlarging womb pushing up the stomach. The author submits these as reasons why puerperal convulsions *during* labour or *previous* to it, are always more tedious or troublesome to deal with than the convulsions which sometimes follow labour—the pressure of the gravid uterus conveyed to an impacted state of the bowels or congested liver, will keep up this form of pressure on the larger veins, and thus throw back a quantity of dark blood into the muscles. The analogy of numerous experiments on the lower animals would also indicate that mere black venous blood of itself is sufficient, and that the blood need not be poisoned with the elements of retained urea, carbonate of ammonia, &c., as theoretically supposed. Hyperæmia alone appears as a sufficient predisposing cause of convulsions, and chiefly by causing congestion of the muscles, and not, as usually supposed, of the vessels of the brain. Even albumen in the urine is of no importance whatever!

As to the form of puerperal convulsions which is seen *after* labour, he is anxious to procure the experience of readers whether this is not usually, or more often "reflex," induced (as in epilepsy) by irritation of uterine nerves, reflected back to the medulla oblongata and spinal column; thus, several cases of puerperal convulsions of late, when carefully examined, were cured by chloroform, and found to be caused by the necessary irritating manipulation of passing a hand into the uterus to remove an adherent placenta; here an irritation purely nervous, starts from the nerves of the uterus or vagina, reaches the spinal cord and

medulla oblongata, and is reflected back upon these very centres (whether through their nutrient nerves or otherwise may be a little doubtful, and not very important to decide), hence morbidly increased action and puerperal convulsions, which differ in a most marked degree from the previous variety caused by dark blood in the muscles or albumen in the urine.

Among these curious sympathies or associations of the genital organs in females, with convulsive diseases, as seen in passing a hand into the uterus, the author would further cite several cases of epilepsy or epileptoid affections, like convulsions, decidedly improved, if not cured, by cauterisation or excision of the genito urinary nerves in irritable parts, as the clitoris, which he has seen during the past two years; a corroborative fact, the converse of this, too, has been noted, that in bad vesico-vaginal fistula cases, or recto-vaginal injury in hospitals, where the normal condition or sympathy of the vagina for a time with the ovary, has been disturbed or paralysed, menstruation usually ceases, but the moment the urine, previously trickling through the vagina, is re-directed into its proper channel by an operation, menstruation is set up again with increased facility of flow; tied and bound together thus, so to speak, are the nerves and nervous associations of the vagina or uterus, and its appendages, each acting, as in puerperal convulsions, through the medulla oblongata and spine.

Irritated ovary, associated with constant bleedings and enlargement, simulating fibrous disease of the uterus, with most marked anæmia (the patient appearing as white as paper), the author has known to resist all tonic or steel hospital medicines (which, in fact, made the pain and anæmia worse), but yield in a few days to a removal of the primary cause of the disease, under chloroform, namely, excision of irritable peripheral nerves as just mentioned; these cases were different from strictured or occluded os or cervix, which they were supposed to be; in 313 cases of puerperal convulsions, treated by chloroform chiefly, and given by Sinclair and Johnson alone in their practice, the chloroform had a decidedly good effect in lessening the "impressionableness," so to term it, of the spinal cord, in all these puerperal convulsions are cases of a reflex nature, but one is *not* so sure of the cases where the irritation, so to speak, is mechanical, by a back current of blood or hyperæmia of the muscles.

It is probable that the use of some medicines, such as opium, tends in no indirect manner to predispose the patient to these hyperæmic convulsions in the puerperal state, not necessarily perhaps so much by inducing uræmia, as by causing an obstinate condition of the bowels and sluggishness of the liver. We are not now concerned with the exact function of the bile or the liver, or if calomel acts on the liver (which some are supposed to doubt!) but these cases are perhaps those where 5 or 10 grain doses of calomel have been supposed to do so much good by unloading the bowels, and preventing pressure on the abdominal veins.

Some of the nervous associations of the uterus are singular and unexpected, like the pain at the tip of the right shoulder from liver disease, is a severe neuralgic pain, well known in hospitals as "hysteric knee-joint," and Mr. Hilton ascribes it to a nerve which he has demonstrated, which goes to the ovary, and sends a long unexpected branch through the obturator opening to the knee-joint, and another to its inside! so that even injury of a knee-joint might simulate ovarian derangement, or *vice versâ* these unusual cases of nervous association, to some persons unintelligible, are mentioned to illustrate why passing a hand into a uterus may produce puerperal convulsions.

There can no longer be any doubt as to the exceeding value of chloroform in ordinary midwifery practice—it is a great charity to the agonised patient in many cases, as when properly administered, it need never interfere with the progress of the labour "pains." One hears occasionally of a case of a labour which partly stopped while the patient was taking chloroform, but we forget that a labour may stop midway without any chloroform at all; one hears often, too, of women rendered deeply insensible for hours together through a labour, but this need not be, as we find it scarcely ever necessary in labour to narcotise the great reflex centre, or destroy consciousness; there are several errors afloat in so-called leading journals as to parturition without pain, and dilution of the chloroform so as to prevent its entering the blood, but such fictions cannot deceive scientific observers. Chloroform, by rigid experiment, is found always to enter the blood in inhalation of the vapour, but not at all to be decomposed in the blood under such conditions.

The writer submits whether this great difference between these two varieties of puerperal convulsions, may not reconcile the vast differences of opinion that exist, even amongst the most experienced accoucheurs as to the usefulness of chloroform in puerperal convulsions. In one class of cases, that from congestion, it can scarcely be expected to act so well, as it undoubtedly acts in the instance where the convulsions depend on abnormal nervous reflex action—it should not be forgotten, indeed, that even in the most ordinary "labour," reflex excitability is much increased by the process of evolution of the child in the uterus, especially if the membranes be once ruptured, when the fœtus becomes, as it were, a foreign body to be then thrown off. If this be subsequently continued by passing the hand into the uterus to remove a placenta, convulsions, as we know, are often excited. But the author believes that in none of the cases is the blood poisoned as usually supposed: *dark venous blood alone excites convulsions.*

It has been recently noted in practice of midwifery that chloroform has a tendency to induce a slight form of *inflammation of the lungs*, by direct action as supposed of the chloroform vapour as an irritant on the air-vessels, but I have never seen this inflammation in hundreds of patients who had had chloroform in hospitals administered for various operations, nor in a considerable experience of midwifery patients who had had the same anæsthetic during labour. I am inclined to believe that in one or two patients in Dublin, for instance, where it was seen it was caused by unnecessary deluging the patient's chest with iced cold water, as a restorative from apprehended syncope; bad chloroform, no doubt, acts when taken internally as a violent irritant or narcotico-acrid, and externally blisters the skin; impure acid chloroform may excite the delicate bronchial capillaries also, but mere chloroform has not been observed to do so, except possibly where slight bronchitis already existed, or the patient's chest was deluged with cold water.

Finally, the ultimate practical conclusions to be deduced from direct experiment on animals—viz., that convulsions ensue where mechanical pressure is made on the *venæ cavæ*, as also from the almost invariable concomitant of chloroform administration (where respiration is impeded), that black blood collects in the veins, seems to be:—I. That similar pressure of a mechanical kind on the abdominal veins by a gravid uterus is one of the causes, or, more correctly, the immediate or chief exciting cause, of one form of puerperal convulsions, the true remedy being to empty the uterus and remove the mechanical pressure.

II. That another very marked form of puerperal convulsions is caused by such irritation as that excited by passing a hand into the uterus, and here chloroform administration is eminently beneficial. And, III. That there is probably no real blood-poisoning in these convulsions, as theoretically supposed in books copied from one to the other, the carbonate ammonia or urea leading to coma, &c.; but rather a state of simple hyperæmia or *remora* of black blood into the muscles in one class of cases, possibly with albumen in the urine, the *bete noir* of practitioners but in reality of no moment whatever, and simple reflex irritability of the uterine organs in the other, as now abundantly proved by sundry forms of convulsive diseases so superinduced, but only recently studied, since the introduction of chloroform, and of clearer views on epileptic convulsive and other allied forms of uterine irritation.

UNIVERSITY COLLEGE HOSPITAL.—Charles Dickens, Esq., has consented to preside at the annual dinner in aid of the funds of this hospital on the 12th of April.

CERTAIN AFFECTIONS OF THE FINGERS AND HANDS.

By Dr. G. de Gorrequer Griffith.

Contraction of the fingers may be dependent on mere spasm of the muscles, or a rigid condition of the tendons; on rigidity and contraction of the palmar aponeurosis or the same condition of the thecæ or sheaths of the tendons, or even upon an alteration of the palmar cellular tissue into ligamentous, which afterwards becomes rigid and contracted.

This incurvation of the fingers from contraction of the palmar aponeurosis has been described as being very frequently, perhaps most frequently, met in letter-stampers, or indeed in any persons, who constantly expose the palm of the hand to pressure; even the having to use a round headed cane in walking, and thus throwing the weight of the body upon the hollow of the palm in each act of progression, has been known to originate the affection. The contraction usually begins in the little finger, and thence spreads to the ring and middle fingers: in many instances it will be traceable to no certain cause, while in many others we may be able to recognise the gouty-rheumatic diathesis, or even the previous existence of inflammation of the deformed digit in connection with this peculiar habit.

The integuments over the ridges formed by the tightly-stretched palmar aponeurosis, or whatever other tissue is the cause of the contraction, may or may not be adherent to them.

It was Dupuytren who, by careful dissection of a hand in which this condition existed, first called attention to the true seat of the deformity, and showed it to arise from the tension and diminution in size of the palmar fascia, and of certain fibrous cord-like bands that above were attached to it, but below had spread themselves out upon the fingers. M. Goyrand considers these bands to be hypertrophied portions of the cellular tissue, rather than prolongations of the dense fibrous aponeurosis.

Sometimes a condition of the hand obtains, to which the nomenclature of club-hand would not be inappropriately applied. We make reference to those cases wherein the *flexor* muscles, being in a state of rigid contraction, curve the hand upon the wrist with varying degrees of intensity, or in which the extensors being at fault draw it forcibly backwards. In either case there will often be found a true congenital dislocation of the wrist or some malformation of the carpal extremity of the radius. To this subject Mr. Smith, of Dublin, Cruveilhier, and Voillermier have devoted themselves and described it minutely. The first mentions the presence in one of his cases of an additional semilunar bone in the affected carpus. The treatment is obvious: division of the tendons, if not of all of them, at least of the most tense; but, in truth, little good can be expected, when the bones themselves are participators in the general malformation.

There is a somewhat rare affection known to the Germans by the name of Schreibekrampf, and to us by that of "Writer's Cramp," in which the following symptoms are demonstrated:—Involuntary spasmodic contractions and tremors of the muscles of the fingers, not, however, at all times present, but perhaps only when the hands are engaged in the performance of acts, requiring nice and delicate manipulation; as in the grasping of a pen or pencil, and the endeavouring to use the one or the other; or in the playing upon an instrument. The conditions may be present individually or both simultaneously, when efforts are being made with the fingers and hands, or even when these latter are not employed in any way. Usually we see the index and the middle fingers and the thumb associated in the lesion; very often these only are affected, while in some other instances the entire hand, or the hand and forearm or even muscles in other parts of the body, are implicated. A not very infrequent complication is torticollis or wry neck from this spastic contraction of the sterno-mastoid muscle on one side, combined or not with the same faulty condition of the antero-clavicular margin of the trapezius.

From M. Duchesne the affection has received the name of functional spasm and functional muscular paralysis.

There may or may not be pain coexistent with the contraction, and the spasm or rigidity may become permanent, having been at first present only when the person attempted the use of the fingers, or paralysis may supervene. The etiology is yet involved in some obscurity. M. Duchesne supposes it to be a deviation from the normal functions of the muscles, dependent upon their too frequent or too long continued excitability or exercise, resulting in either the spastic rigidity or the condition of paralysis; and further considers that the disease at first localised many become extended to the spinal cord, so as ultimately to involve it.

The treatment by Faradisation in some instance will be attended with success, while in others it will prove wholly inefficient, and then we must resort to mechanical contrivances for the relief of the overtaxed and exhausted muscles.

We are quite conversant with the facts, that the smaller the object to be held and the greater the amount of labour thrown upon any particular set or sets of muscles, the more weariness and exhaustion will be induced, and the more readily will this malady be excited; while by maintaining a continuance of these excitant causes of the affection aggravation will be the sequence and this in turn will result in a chronic form of the malady, if no treatment be pursued.

Based upon the knowledge of these facts are the objects sought to be obtained by the different appliances put into requisition.

Cazenave mentions the case of a clerk, who, suffering from the disease under consideration, and unable to prosecute his work, devised an instrument by which the stress was taken off the affected muscles and writing performed by means of the muscles of the forearm. The contraction and spasms may be removed by bracing the entire forearm in an elastic or even an unyielding bandage.

Some instruments are fixed between the index and second fingers, so that the entire hand from the wrist can be used and with little, if any, fatigue to the patient.

"This plan has a similar effect to that of the wire and pin combined; by repeated tightenings, the wire gradually effects a passage by ulceration through the veins, which are obliterated by the same process."

The objection urged against the radical cure is, that though the disease be removed, there is in its stead, induced atrophy of the testicle.

M. Mathieu's plan is to fix the pen to the first finger by means of rings, at the same time that the thumb is firmly supported by a semilunar rest, which also keeps it apart from the index finger; by this contrivance, great mobility of the hand and facility of writing are gained at the expense of very little exercise; the muscles of the hand being incorporated with the instrument and remaining almost passive agents.

The instrument constructed by M. Velpeau consists in a fluted ovoid ball, which, to suit the convenience of the patient, may be made of any size; the ball fits into the hollow of the hand and has affixed to its narrow extremity a moveable penholder, which on account of this mobility, can be adjusted to any angle that will enable the writer to use his pen with the greatest ease; the fingers are supported by rings, and are thus relieved of the weariness, which otherwise would result from their long-continued and constant use. The wider the fingers are kept apart by the instrument, the greater is the comfort afforded the sufferer, and of course the longer is the period during which he can pursue his avocation. It is of advantage to change the instrument from time to time, or to vary it in some way or other; nor should we lose sight of the fact, that, not at all times nor in all cases are the same muscles affected.

Messrs. Charriere and Mathieu have variously modified the pen-holder of M. Velpeau.

A cure of this affection may be attempted—and with success—by means of the hypodermic injection of the muriate or acetate of morphia, or the sulphate of atropine.

M. Stromeyer resorted to the acupuncture of the small muscles of the thumb, but the relief being merely temporary he then employed setons, which he introduced through the same muscles; the setons were each morning saturated with the extract of belladonna or with a solution of opium.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. IV.

ARSENIOUS ACID.—A process for the purification of arsenious acid has been introduced into the British Pharmacopœia from that of the Dublin College. It consists in submitting the "arsenious acid of commerce" to re-sublimation. If by "arsenious acid of commerce" we are to understand the common powdered arsenic of the shops, the resublimation is advisable, since this article is sometimes largely adulterated with sulphate of lime or baryta, and may also contain some sulphide of arsenic, which latter, however, will not be got rid of by the Pharmacopœia process. But the vitreous acid, in opaque or semi-transparent masses, described by the London College in 1851, and which is always procurable, is sufficiently pure for all purposes, and needs no further treatment. Either this, then, must be employed in pharmacy, or the powdered arsenic must be sublimed as directed.

Arsenious acid is obtained by roasting arseniferous minerals, chiefly arsenical pyrites, in a current of air. The double sulphide of arsenic and iron is decomposed, metallic arsenic is vaporised and oxidised by the air, and sulphide of iron remains behind. The first product is deposited in the flues or chambers of the furnaces as a dirty grey powder, and is usually contaminated with metallic arsenic, sulphide of arsenic, and some earthy impurities. This is resublimed with a little potash to retain the sulphur, and arsenious acid is then obtained as a transparent colourless glass, which in the course of a short time becomes opaque externally, and gradually so throughout. This opacity has been variously ascribed to a simple molecular change, and to the absorption of water. In contradiction of the latter supposition, Dr. Christison asserts that the glass will keep transparent under water for years.

When resublimed in small quantities according to the directions of the British Pharmacopœia, arsenious acid is obtained in the form of a heavy white powder. Two tests are given for determining its purity. First, it is said to be entirely volatilised by heat, which has been already proved by the sublimation. The second is a volumetric determination by means of a standard solution of iodine, directions for the preparation of which are given in appendix B. A solution is there directed to be prepared which shall contain $\frac{1}{10}$th of an equivalent in grains of iodine in 100 measures. Some iodide of potassium is also ordered merely to promote the solution of the iodine. Four grains of arsenious acid dissolved with eight grains of bicarbonate of soda will decolorise 80·8 measures of the solution of iodine.

The rationale of this process is extremely simple. Iodine is an energetic oxidizer, and arsenious acid, As O_3 has a great disposition to form arsenic acid, As O_5. When, therefore, arsenious acid is brought into contact with iodine in the presence of water and an alkali, it is converted into arsenic acid.

There are two points worthy of notice in this process: In the first place, the iodine solution should be freshly prepared, since by keeping the iodine is liable to decompose water, and form hydriodic acid, by which the strength of the solution would be materially altered. In the next place, the termination of the reaction is inferred when the iodine solution ceases to be decolourised. A plainer indication is afforded by adding a little "mucilage of starch" to the arsenical solution, which gives the well pronounced blue colour as soon as the iodine is in the smallest excess.

For those unused to the practice of volumetric analysis, the directions of the Pharmacopœia of 1851 offer a much simpler method of ascertaining the purity of arsenious acid. In that work it is stated that "if 100 grains of this acid are boiled with hydrochloric acid and sulphuretted hydrogen added when the solution is cool, 124 grains of sulphuret of arsenic are precipitated."

The chemical characters of arsenious acid are very briefly described in the Pharmacopœia. It is said to be "sparingly soluble in water;" but the solubility is much influenced by the circumstances under which it is effected. If a great excess of arsenic is boiled for some time in water, the hot solution will contain about 1 of arsenious acid in 8 or 9 of water; if it be allowed to cool for some hours it will contain about 1 in 20; after three days, about 1 in 40; after a week, about 1 in 50, and in a fortnight, about 1 in 60, which is the normal proportion. But if arsenic is merely shaken with cold water, the solution is exceedingly slow. The solution gives with ammonio-nitrate of silver, a canary-yellow precipitate, insoluble in water, but soluble in ammonia and nitric acid. This test often fails in the hands of inexperienced experimenters, but will always succeed if the ammoniacal nitrate solution be prepared according to the directions of the Pharmacopœia adopted from that of the Edinburgh College. The chief source of failure is the presence of an excess of ammonia, which instantly re-dissolves the precipitate. In preparing the test solution, it is therefore recommended that the ammonia be added cautiously to the nitrate of silver, so as nearly, but not quite, to dissolve the oxide of silver first thrown down.

The foregoing tests will suffice for the recognition and determination of arsenious acid, so far as pharmaceutists are concerned. The toxicological relations of the acid may require notice at a future time. Liquor arsenicalis, for the preparation of which arsenious acid is placed in the Materia Medica, will be noticed in its proper place.

BENZOIC ACID.—This acid is a constituent of several resins, gum-resins and oleo resins—as dragon's-blood, gum benzoin, vanilla, storax, and the balsams of Peru and tolu. It is directed by the Pharmacopœia to be prepared from gum benzoin by sublimation. Elaborate directions are given for putting the benzoin into an iron pot, and covering it with a pasteboard cylinder twice its diameter, which is to collect the benzoic acid when heat is applied to the bottom of the pot. The yield of acid obtained in this way is small (only 4 or 5 per cent.), but it is pure, and, moreover, very fragrant, from the presence of a small quantity of a volatile oil which accompanies it. A larger amount of the acid (from 12 to 18 per cent.) is procured by first digesting and then boiling the benzoin with milk of lime, so forming a soluble benzoate of lime, from which the benzoic acid may be thrown down by the addition of hydrochloric acid. The benzoic acid so obtained may be collected and pressed, and then sublimed to free it from any adhering chloride of calcium; but the product is never so fragrant as that sublimed directly from the benzoin. It may be used, however, for the preparation of benzoate of ammonia.

The physical characters of benzoic acid are well known. It is sparingly soluble in cold water to the extent of about 1 part in 480 of water. It is much more soluble in boiling water, (1 in 24), and freely in alcohol. It is also freely soluble in alkalies and lime, but separates on the addition of hydrochloric acid, unless the solution be very dilute, when the benzoic acid is held in solution by the water.

The test, complete sublimation on the application of heat, will prove the absence of fixed impurities, but would not reveal the presence of benzoate of ammonia, if a manufacturer were disposed to practise that not very profitable adulteration. Benzoic acid melts at about 248° Fah. and begins to sublime at 309°, boiling freely at 462°.

Benzoic acid is employed in the Pharmacopœia for the production of benzoate of ammonia, in speaking of which we shall have to notice the change which the acid undergoes when taken into the system. It is also an ingredient in Tinctura Camphoræ cum Opio, as Paregoric, is now called.

CITRIC ACID.—In the British Pharmacopœia, the formula 3 HO, C_{12} H_5 O_{11} + HO = 201, is ascribed to citric acid. An acid of this composition, however, is never found in commerce, nor is it likely to be obtained by the Pharmacopœia process, unless the solution is boiled down almost to dryness, when only small crystals will be formed.

The ordinary acid of commerce is crystallised with two atoms of water 3 HO, C_{12} H_5 O_{11} + 2 HO = 210, a fact of some importance to remember, when it is wished exactly to neutralise the acid with an alkali.

Citric acid is found in lemon-juice, together with mucilage and other vegetable matters. To separate these, the Pharmacopœia has recourse to an old and very good process, which consists in submitting the juice to fermentation before the acid is precipitated by lime. It is of importance that the fermentation should be complete before the addition of the lime, as the neutralised acid would otherwise also ferment and form acetic and butyric acids. Much of the vegetable matter is decomposed by the fermentation, and the juice is clarified by the subsidence of the yeast. When the fermentation is over the clear juice is run off, boiled, and while hot, is neutralised with chalk. The precipitate is collected and washed with hot water, in which citrate of lime is less soluble than in cold. It is precipitated from a hot solution for the same reason.

After the precipitate has been well washed, it is mixed with distilled water, and decomposed by means of sulphuric acid. The sulphuric acid must be added very gradually, and the mixture kept constantly stirred, or it gets lumpy. The reaction is very simple: sulphate of lime is precipitated, and the citric acid is set free. After the sulphate of lime has deposited, the clear solution is run off, the precipitate is washed, and the washings added to the clear liquor. The whole is then evaporated to the density 1.21, and allowed to stand for twenty-four hours for any sulphate of lime to crystallize out. The liquor, separated from these crystals, is further evaporated, until a pellicle forms, and then set aside for the citric acid to crystallize.

Citric acid is an example of a tribasic acid, that is, an acid requiring three equivalents of a base to form a completely neutral salt. Hence it is stated in the Pharmacopœia, "that sixty-seven grains," (one-third of an equivalent), "are neutralized by 100 measures of the volumetric solution of soda," which contain one equivalent (31 grains) of soda.

It is important to remember the tribasic nature of citric acid when prescribing and calculating the amount of alkaline carbonates to be employed in effervescing mixtures, or to form neutral salts. We append a table of the quantities of the most commonly prescribed carbonates that are necessary to exactly neutralize twenty grains of the acid.

Sesquicarbonate of ammonia	16·86	grains
Bicarbonate of potash	28·56	„
Carbonate of potash	24·85	„
Bicarbonate of soda	24·00	„
Carbonate of soda (crystals)	40·85	„

The above numbers are, of course, calculated for the acid of commerce, the equivalent of which is 210.

The acid is soluble in three-fourths its weight of cold water and in half its weight of hot; and it is also soluble, but not to the same extent, in spirit.

Citric acid, when gradually heated without access of air, yields a variety of products of much interest to the chemist, but not to the Medical practitioner or pharmaceutist. When burned with free access of air, it is completely consumed, which would not be the case if, by carelessness or

design, the crystals of sulphate of lime were not separated. Its aqueous solution is not darkened by sulphuretted hydrogen, showing the absence of metallic impurities. It gives no precipitate when dropped (sparingly) into lime water, but a cloudiness will be produced if the mixture is boiled. No precipitate is produced when the solution is added in excess to a solution of acetate of potash, which distinguishes citric from tartaric acid. Lastly, no precipitate is obtained with chloride of barium, which proves the absence of sulphuric acid.

A neutral citrate of potash has now been introduced into the Pharmacopœia, which will save the trouble of writing prescriptions for the production of this salt *extempore*.

THE MEDICAL PROFESSION AND CERTIFICATES OF LUNACY.

At an extraordinary meeting of the Royal College of Physicians of Edinburgh, held on February 19, 1864, the following resolutions were moved, seconded, and unanimously agreed to:—

"1. That the Royal College of Physicians of Edinburgh recognises it to be its duty, in accordance with its original charter (1681), to promote Medical science, and also to protect the interests of the Medical Profession and of the public; and that, accordingly, the College has endeavoured, on various occasions, to establish a sound relation between the Profession and the public in the matter of certificates in lunacy.

"2. That the duty of signing certificates in lunacy is one at all times painful and disagreeable, and one peculiarly liable to bring the Medical man discharging it into collision with the patient or his friends; and therefore one, of which, were it practicable, the College feels satisfied the Professson would gladly be relieved.

"3. That the duty of signing certificates in lunacy appears, nevertheless, to the College, indispensable as a part of Medical practice; and that both the public interest and the welfare of the insane themselves require that it shall be performed as freely as is consistent with proper securities against abuse.

"4. That the peculiarity of the position of Medical men in signing such certificates is, that they are thereby brought in contact with persons who are not in full possession of their senses, and who, even after their discharge from an asylum, frequently retain a prejudiced or revengeful feeling against those by whom they were placed under treatment.

"5. That the Royal College of Physicians approves of every reasonable security being given to patients and their friends, in regard to confinement in asylums, and therefore was in favour of Section XXXVIII. of the Lunacy Act (Vict. 20 and 21, cap. 71), which provides that, 'If any person shall grant any such certificate or statement as aforesaid without having seen and carefully examined the person to whom it relates, at the time and in the manner specified in such certificate, with a view to ascertain the condition of such person to the best of his knowledge and power, he shall be guilty of an offence, and shall for every such offence be liable in a penalty not exceeding 50*l.*; and if any person shall wilfully and falsely grant any such certificate, to the effect of any person being a lunatic, the person so granting such certificate shall be guilty of an offence, and for every such offence be liable in a penalty not exceeding 300*l.*, or be liable to imprisonment for any period not exceeding twelve months.' Prosecutions for these offences would be undertaken by a public prosecutor, who may be supposed to act without prejudice in the matter.

"6. That the Royal College of Physicians has repeatedly endeavoured, during the progress of recent legislation in lunacy, to secure the introduction into bills before Parliament, of clauses extending to Medical men some protection, unless in cases where they have signed certificates in lunacy without 'probable cause.'

"7. That the Royal College of Physicians is still of opinion that the legislature, which imposes by statute on Medical men the duty of signing certificates in lunacy, is bound to give them some protection in honestly endeavouring to discharge that duty. The College therefore instructs the Council to spare no efforts to secure the introduction of a clause affording some protection, into any measure which may be brought before Parliament during the present Session."

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

FEBRUARY 23.

VACCINATION OF SHEEP.

Sir J. C. JERVOISE asked the Secretary of State for the Home Department whether the experiments in vaccinating sheep were yet concluded; and, if so, when the results would be laid before Parliament.

Mr. LOWE said,—The experiments in vaccinating sheep concluded last Michaelmas, and I am sorry to say that the result is exceedingly unsatisfactory. I am also sorry to say that the report is not yet ready to be laid before Parliament. The framing of that report is in the hands of a gentleman who is not officially connected with the Government, and who, I think, has taken a deal more time than was necessary in its preparation. I am assured, however, that it will be ready by Easter. As I am not able to produce the report, I may state its general effect. The experiments that have been made are of two kinds. One has consisted in vaccinating sheep with lymph taken from the human subject, and this has succeeded in some measure. The sheep took the disease, though in an irregular and abnormal form (laughter), but when we came to test the value of that vaccination, we found that the sheep took the virus either by inoculation or in the natural manner from other sheep, so that vaccination thus accomplished appears to be futile. The next plan was to inoculate cows with matter taken from sheep, in order, if possible, to produce a vaccine disease in cows which would stand in the same relation to sheep as cow-pox does to the human subject. But we entirely failed in producing that disease (laughter), and therefore the result of the experiments was altogether unsatisfactory.

INSANE PRISONERS' ACT AMENDMENT BILL.

Sir G. GREY moved that the report on this Bill be agreed to.

Mr. HUNT said that when the Bill was in Committee he had stated that "Dr. Forbes Winslow had based his opinion of Townley's insanity chiefly on his extraordinary perverted moral sense." It had been represented to him that this was not a correct statement of Dr. F. Winslow's theory of the case, which was that there was great moral obliquity in Townley, and with this a mental aberration; and, viewing these conjoint conditions, Dr. Forbes Winslow came to the conclusion that he was not of sound intellect. He (Mr. Hunt) did not see much variance between this correction and what he had himself stated, but he was anxious not, in any degree, to misrepresent Dr. Forbes Winslow to the House. He protested against moral obliquity being taken into consideration at all in estimating the sanity or insanity of a prisoner. (Hear, hear.)

The report was then agreed to.

FEBRUARY 24.

The Insane Prisoners' Act Amendment Bill was read a third time and passed.

POOR LAWS.

The following members were nominated to form the Committee on the Poor Laws:—Sir J. Acton, Mr. Bazley, Mr. Bouverie, Sir G. Bowyer, Mr. Caird, Lord R. Cecil, Lord Fermoy, Lord E. Howard, Sir W. Jolliffe, Mr. Locke, Mr. Lowe, Mr. Lyall, Mr. Kekewich, Mr. Neate, Colonel Pennant, Mr. Alderman Sidney, Mr. Tollemache, Mr. Walpole, and Mr. Villiers.

THE MEDICAL CIRCULAR.

WEDNESDAY, MARCH 2, 1864.

GRATUITOUS MEDICAL SERVICES.

The subject of gratuitous Medical services has often been discussed, but it is impossible that the topic should be exhausted while the manifold evils engendered by the present system are in operation. The solution of the question really rests with the Profession itself, for if Medical men would combine together to discourage the present state of matters, the public would be compelled to adopt more equitable views as to the remuneration of Medical labour. But while we afford our services gratuitously and indiscriminately, the recipients of our generosity estimate them at the value we ourselves set upon them, which is nothing at all. That which is easily obtained is lightly esteemed, and labours which are gratuitously performed are considered worthless.

It is probably in the large towns and cities where the system acts most injuriously upon the Medical Profession. In the country districts, the pittance, small as it is, which is doled out by the Poor-law Guardians, is supplemented by the annual payments made in most localities by the members of clubs, and thus, independently of private connexions, a Medical practitioner may eke out a tolerable income. In fact, in these rural regions, the system of gratuitous Medical services can scarcely be said to exist, for the lowest classes fall under the operation of the Poor-law, the class just above these obtain Medical relief by means of their clubs, and those who are tolerably well to do in the world, of course remunerate their Medical attendants.

But in the great centres of population and industry, where poverty is necessarily wide-spread, the benevolence of individuals and communities has furnished for the destitute and the diseased, the means of obtaining the best Medical and Surgical advice by means of the establishment of hospitals and dispensaries, against which, as long as they exercise their legitimate functions, no objection whatever can be raised. But it is a very different thing when the stream of charity is diverted from the channel in which it was intended to flow, and is poured out in lavish abundance before a class of society who are not at all entitled to partake of the benefits it confers. The indiscriminate administration of Medical relief at many of our large hospitals and dispensaries, is calculated only to pauperise the Medical Profession, and to lower the value of Medical and Surgical labours in the eyes of the populace. Nor is this all: for the enormous number of patients who avail themselves of the boon thus offered, and the comparatively small staff by whom the benefits are distributed, necessarily lead to careless habits of prescribing and administering medicines, and thereby bring Medicine itself into general disrepute. The labours of the assistant-physicians and assistant surgeons at our large hospitals are perfectly herculean, and they are undertaken only in the hope that the labourers may one day reach to the superior posts; while the results must be unsatisfactory to the patients from the little care bestowed upon individual cases. The private Medical practitioners in the neighbourhood of these great institutions are seriously injured by this abuse of charity, and the profits which they might naturally anticipate from attendance on the sick, are ruthlessly snatched from their grasp.

But not only is the out-patients' room of a large hospital filled with a motley crowd, many of which ought to be attended by the Poor-law surgeons, and many who are quite able to pay for Medical advice, but well-to-do tradesmen and others avail themselves of the advantages offered by the interior of the hospitals, and thus cheat the charity in the first place, and the Medical Profession in the second. We have heard of persons in what are called the middle ranks of life, and even persons possessing considerable property, who have from mere sordid motives availed themselves of the food, shelter, medicines, and appliances obtainable in the wards of our great hospitals, and have thus alienated from the pockets of the general practitioner a portion of his legitimate income. We are quite aware that in some hospitals, private wards exist for the accommodation of persons who, being alone in our great cities, repair to these institutions for the benefit of Medical advice and good nursing, and who pay a certain definite sum for the advantages thus conferred upon them, and to such cases our remarks do not apply; but surely it is a monstrous perversion of charity for people who are able to pay their butcher and baker, and perchance their publican and their gin-shop keeper, to apply for and to accept Medical attendance and medicines as if they were paupers, and thus to defraud some struggling member of our Profession of his emoluments.

The dispensaries, again, as they are at present too generally conducted, exhibit merely the abuse of Medical charity, doing but little good to the sick, doing nothing for the Medical staff, and hardly anything for the advancement of Medical Science. They were no doubt originally intended to meet the wants of a class of persons, who were above the grade of paupers, but below the paying part of the community; and this class is a pretty well defined one, consisting of servants, persons receiving small wages, small shopkeepers, and numerous artisans. We do not allege that many such persons are not fully entitled to the benefits which a dispensary can bestow, but the fact is, that those for whom the dispensaries were designed, are thrust out of the way by the pauper class on the one hand, and by those who can afford to pay on the other. Hence the waiting-room at a dispensary presents an incongruous assemblage of wretched creatures, who require food and raiment rather than medicines, mingled with persons whose attire and demeanour prove that they are quite able to pay for medicine as well as the other necessaries of life. By the one group, the Poor-law surgeon diminishes his visiting list; by the other, the private practitioner suffers an appreciable loss of emolument. The

dispensary physician or surgeon goes through his duties in a merely perfunctory manner, as in ninety-nine cases out of a hundred he gets nothing for his services, and the recipients of his kindness perhaps secretly despise him for rendering it.

The remedy for this state of things is, as we commenced by remarking, in our own hands, and we are bound to discourage, by every means in our power, the present system of gratuitous Medical relief. The present dearth of candidates for the Medical Department of the Army, and the consequent concessions, few as they at present are, made by that Department, prove that combination is essential towards gaining a desirable object, or suppressing or remedying an abuse, and, in like manner, if the members of our Profession would steadily set their faces against the acceptance of gratuitous appointments, the latter would no longer be offered, and it would at last be admitted, in fact as well as in theory, that "the labourer is worthy of his hire."

SUMMARY OF THE WEEK.

MEDICAL EDUCATION.

The subject of Medical Education, and the improvements of which the present system is susceptible, are at present beginning very justly to occupy the attention of the Profession. The observations made by Mr. Syme on this topic, and the extravagant views which he has propounded in a recently published pamphlet, have been fully commented upon by ourselves, but the theme is too important in all its bearings not to require much further discussion. What may have been Mr. Syme's own motives in ventilating the question, whether for the purpose of damaging some of his own colleagues, or decrying the English and Irish Schools of Medicine we do not pretend to determine, but we are at any rate gratified to find that our own opinions as to the absurdity of his views are pretty generally received, even in the city and in the university where they were first promulgated. In our further remarks upon this important subject, we shall lose sight of Mr. Syme, and examine it in its broad bearings upon the intellectual and scientific training of the Profession, and consequently upon the welfare of the community. It unfortunately happens that the lips of those who are most competent to give their opinions are sealed; for the teachers, on the one hand, are naturally unwilling to make disclosures which may affect their own pupils, and the examiners, on the other hand, are bound in honour not to reveal the shortcomings of those who present themselves as candidates for professional diplomas or licenses. In the absence, therefore, of all correct knowledge on the subject, it is the custom to believe that all students are diligent searchers after professional knowledge, and unsuccessful in the attainment of that object; that most teachers are careless and inefficient; that all licensing bodies are extravagant in their demands upon the student's time; and that most examiners are unfair in their mode of conducting examinations. The natural waywardness and fickleness of youth are hardly ever alluded to; the difficulties experienced by the most zealous teachers in engaging the attention or encouraging the zeal of their pupils are very rarely touched upon, if at all; and the puzzling problem often presented to examiners as to the real or fictitious character of the pretensions of candidates, is seldom alluded to. In fine, all the defects of the present system are attributed to the teachers, the examiners, and the licensing bodies, and none to the students themselves; while it might with far more truth be urged that, inasmuch as every one is, in fact, the architect of his own fortune and reputation, the evils of any system might be overcome by individual energy and perseverance. It is true that in some schemes of Medical education the students are overworked, but in very many cases the fault lies in exactly the opposite direction.

THE ARMY MEDICAL DEPARTMENT.

We by no means agree with some of our contemporaries in their wholesale denunciations of the Army Medical Department, and we entirely disapprove of that unfair spirit of exclusive nationality which can point to the number of Irish successful candidates as a proof of the inferiority of the present Medical Officers as a class. Indeed, without wishing to make any unfair comparisons, we consider the Irish School of Medicine to be in the highest state of efficiency, and that its alumni are, therefore, qualified to spread the lustre of their *alma mater* throughout the world. In former days, the success of the Scotch in a similar manner was pointed at with something like envy and detraction, but for our own parts we look upon the natives of every part of the British Islands as one united brotherhood, inheriting the zeal and energy of the Anglo-Saxon race, from which they all have their common origin, and qualified to carry the glory of British arms and British science to every part of the globe. We consider it, therefore, no discredit to the Army that the number of its Medical Officers should be largely recruited from the natives of the Emerald Isle, but we certainly regret that the competition for the vacant appointments has not been greater than it actually has been. Much of this disinclination is undoubtedly to be attributed to the vehement attacks made upon the Medical Department by some of the Medical Journals, though probably many other reasons, both of a public and a personal nature, have contributed to the result. It ought to be the object of the chief Military authorities to attract the best-educated class of students to the Medical Department, and the late deeply lamented Lord Herbert and the late Mr. Alexander, the chief of the Medical Department, laboured earnestly to that end; and it is very much to be regretted that the present Director-General appears to have pursued a retrograde course, the effect of which has been to create distrust and dissatisfaction among the Medical Officers. Under the circumstances of the case, and in order to supply the existing vacancies, some of the restrictions relating to candidates have been removed, and all persons, legally qualified to practise, and under thirty years of age, are admissible as candidates for the service, and another

examination will be held during the present month for the purpose of determining the successful competitors.

MR. GRIFFIN AND THE POOR-LAW MEDICAL SERVICE.

While the Army Medical Service is languishing for want of candidates, the Poor-law Medical officers continue to fulfil their ill-remunerated duties, and when any one resigns his appointment there are plenty of aspirants to fill his place. It is not very easy to explain the preference thus entertained and acted upon for the sway of the Poor-law local Guardians over that of the commanding officers of regiments. With all their faults, these latter are for the most part gentlemen, and the former are for the most part not so. Perhaps the strong tie of home, even with many attendant discomforts and annoyances, outweighs the love of enterprise which characterises a soldier's life, but otherwise it strikes us that the tyranny of the local guardians is even worse than the tyranny of the Army. We wonder, however, that the same tactics which are now being so successfully tried in the case of the Army, are not practised with the Poor-law Board. If the wretched pittances offered by the Guardians were contemptuously rejected by the Profession, and our brethren would combine together in the determination not to apply for offices unattended with suitable remuneration, there cannot be a doubt that the salaries would be arranged on a more equitable scale. In the meantime, it is only right to press upon the attention of the Legislature the hardships now endured by the Poor-law Medical officers, and it will be perceived, by reference to another part of our columns, that our indefatigable friend, Mr. Griffin, is again at work, vigorously doing battle in a good cause. We regret to find that he recives but inadequate support from his fellow-sufferers of the Poor-law service, but we hope that his present appeal will not be made in vain.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. REDWOOD, of the Pharmaceutical Society, contributes his First Lecture on the "British Pharmacopœia." He contrasts the present Pharmacopœia with the last London Pharmacopœia, pointing out the substances which have been omitted, those which have been introduced, and those which have changed their names. The lecture consists, for the most part, of a pretty sharp criticism of the new work, and it shows that many of the processes detailed are unsuitable for the purpose for which they are intended, and that many of the drugs have not, and cannot have the composition which is assigned to them. Thus, in the preparation of hydrochloric acid, the compilers of the Pharmacopœia have accidentally omitted to direct the application of heat; the sulphuric acid described (HO SO_3) is not suited for general use, and is not the acid of sp. gr. 1·846; the carbonate of potash is an inconvenient product; the spirit of nitrous ether cannot be obtained by the process recommended, and the same remark applies to collodium.

Mr. PRESCOTT HEWITT concludes his Clinical Lecture on "Caries and Necrosis of the Bones of the Skull," and describes a number of cases illustrating these affections. In some instances, serious consecutive symptoms have attended caries of the cranial bones, as inflammation of the membranes of the brain, softening of the brain, hernia cerebri and fatal hæmorrhage from some artery, or sinus, or vein, between the skull and the brain. As to the treatment of these affections, the plan in the present day is, for the most part, to let them alone, and not to attempt to destroy the diseased bone, as was formerly done, but in a few instances the cautious use of the trephine may be necessary. Dr. MURCHISON offers some "Observations on Gastro-Colic Fistula," an affection to which he has previously directed the attention of the Profession. He relates the particulars of two cases of the kind, one of which occurred in his own practice, confirming the views he has already expressed. He considers that a careful study of the cases already on record leads to the conclusion that the concurrence of lienteria and fæcal vomiting, following on the symptoms of cancer, or of simple ulcer of the stomach, renders the diagnosis of gastro-colic fistula almost certain.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. GARROD continues his lectures, delivered at the College of Physicians, on the "British Pharmacopœia." We have already given an abstract of the subjects introduced by Dr. Garrod, in our number of the 10th of February. In reference to the use of manganese in medicine, the following are the experimental proofs of the dubious efficacy of this metal:

"Some few years since, the *Sulphate of Manganese* was proposed as a purgative, and was considered to be useful as a cholagogue. In doses, of from an eighth to a quarter of an ounce, it purges somewhat like the sulphate of magnesia, and bilious actions are often the result; but I am not certain whether it influences the biliary organs more than other cathartics; it can scarcely be said to be used for this purpose at the present day.

"Lately, however, first in France and afterwards in this country, some of the salts of manganese, more especially the carbonate, have been introduced as remedial agents; and it has been argued that the blood corpuscle contains manganese as well as iron, and that a variety of anæmia may exist, dependent not upon any deficiency of the ferruginous compounds, but from the want of manganese; and that when such is the case, the exhibition of the salts of this metal proves curative, even when iron has been previously administered without advantage. About five years since I had an opportunity of trying the action of manganese salts in several cases of well-marked anæmia, accompanied with amenorrhœa, and the mode in which the observations were conducted was as follows:—

"After admission into the hospital, the patients were placed for a week or two upon a generous diet, without medicine, and the influence of this treatment noted. This precaution was necessary, especially in hospital patients, as anæmia may be kept up, if not produced, by bad air, hard work, and insufficient food. If no marked amelioration ensued, the manganese was administered to some in the form of the crystallised sulphate in doses of about five grains. To others a mixture was exhibited, made as Mistura Ferri, or Griffiths' Mixture, with the substitution of sulphate of manganese in place of sulphate of iron; and to a third set, the carbonate of manganese was ordered in the form of powder. In no single case could the hæmatinic powers of manganese be discovered, although the use of

the preparations was continued for some weeks; but in every instance where iron salts were afterwards administered, speedy recovery ensued.

"It is a somewhat remarkable and suspicious circumstance, that when manganese was first proposed as a remedy in anæmia it was given alone; but after a time, double salts of manganese and iron were substituted. These are, doubtless, of value, if only from the iron contained in them. I have no experience of the use of the manganese salts in other forms of disease, and, with regard to their power in restoring the condition of the blood in anæmia, can only say that as yet it has not fallen to my lot to find any case that has been cured by them; and I think I have had sufficient experience in their use to justify my feeling some considerable doubt of their hæmatinic properties."

The following clinical evidence is given as to the value of glycerine used internally.

"Glycerine has been proposed and frequently given as a substitute for cod-liver oil. Even as far back as 1848, when this principle was little known, I made many trials of its value, employing it in cases where I should otherwise have ordered cod-liver oil; the results of these observations may be thus summed up:—although in phthisis it not unfrequently allayed the irritation of the cough, probably in the same manner as syrups and mucilaginous fluids would do, yet it exerted no marked influence over the progress of the tubercular disease, and in no way could it be looked upon as a substitute for cod-liver oil.

"Within the last few years I have not only verified the general truth of this statement, but have likewise been able to make some definite clinical observations upon its action. A patient was selected with a small amount of tubercular deposition, one in whom the activity of the disease appeared to be arrested, but who had not regained flesh; his weight was accurately determined, and he was then placed on cod-liver oil; a steady increase of weight ensued, averaging a pound each four days; after a short time the use of the oil was discontinued, and with this there was a check to increase of weight. Glycerine in the same doses was next given, but with no further increase of weight during a week or so. Cod-liver oil was afterwards again administered, and the same result followed as on the first occasion.

"Observations of a similar kind upon several patients have convinced me that glycerine possesses none of the therapeutic properties for which cod-liver oil is so highly prized—no power, in fact, of arresting waste in the system. Glycerine may be made use of for the purpose of sweetening articles of diet when sugar is objectionable, for example, in diabetes."

Mr. JOHN WOOD continues his paper on "Rupture," and describes some truss-pads devised by himself for the treatment of oblique and direct hernia. He remarks, however, that trusses seldom effect a cure, and he has, therefore, invented and practised a surgical operation which has been successfully introduced with this object. Mr. F. A. BULLEY describes a case of "Rupture of the Ligamentum Patellæ occurring some time after a Fracture of the Bone." Mr. Bulley believes that no case exactly similar has ever been recorded by Surgical writers.

THE 'MEDICAL MIRROR,' FEBRUARY, 1864.

The present number of this new journal contains several original communications of considerable interest. The first is by MR. HENRY SMITH of King's College Hospital, on some "Cases of Tracheotomy, with Observations on its Employment in Diphtheria." Mr. Smith has published some former papers on the same subject, but of late years the operation has become comparatively much more frequent, and in consequence of its earlier performance, much more successful. Mr. Smith relates the particulars of several successful cases, and proposes to continue the series. DR. T. HILLIER offers some "Clinical Remarks on Cerebral Diseases in Children," and shows the difficulty of distinguishing tubercular from other diseases of the brain and its membranes. In one of the cases supposed to be connected with tubercular disease, no tubercles were discovered after death, and in another, which Dr. Hillier believes to have been an instance of tubercle in the brain, the patient recovered under the use of cod-liver oil and iodide of iron. MR. HENRY POWER relates some "Cases of Irido-Choroiditis treated by Division of the Ciliary Muscle, with Remarks on the Relative Value of this Operation and Iridectomy." Mr. Power gives the preference to the division of the ciliary muscle, which, he thinks, affords the necessary amount of relief without the dangers attendant on the injury to the iris caused by iridectomy. DR. CHARLES DRYSDALE communicates a paper on the "Evidence against the Internal Use of Mercury in Syphilis and other Diseases." The arguments adduced by Dr. Drysdale have been frequently noticed in our columns, and a similar remark may be made on the next paper which is entitled "Suggestions Respecting the Best Method of Establishing and Conducting a Village Hospital." The rest of the journal is made up of a Review of Books, and a Retrospect of British and Foreign Medical Journals, together with the news of the past month.

THE 'SOCIAL SCIENCE REVIEW.' Edited by B. W. RICHARDSON, M.A., M.D. February, 1864.

DR. RICHARDSON continues his paper on the "Diseases of Overworked Men," and he now treats of "Broken Heart," not of course in the literal signification of that term, but in reference to the fatal diseases, in which the heart is more or less affected in consequence of undue exertion and disappointed hopes. In an article entitled Journeying through the Air, the writer proves, perhaps rather unnecessarily, that a man cannot fly, but he shows that a parachute may in some measure be guided in its course downwards. MR. J. N. RADCLIFFE, who is a Medical man, and was attached to the staff of Omer Pascha, in the Crimean war, contributes the substance of a lecture lately delivered by him, entitled "Under Canvas, or the Real and Ideal of a Volunteer's Life," in which he gives some graphic descriptions of the memorable transactions in the Crimea, and comments on the great waste of human life produced in time of war, not by the hands of the enemy, but by preventible causes. Under the title of "Capital Murder," the subject of capital punishment is ably discussed, and the practice vigorously denounced as being inoperative in its results, and as inconsistent with the doctrines of Christianity. DR. HUNT'S book on "The Negro's Place in Nature" is the subject of a review, the reviewer disagreeing with the opinions advanced by the author. Among the miscellaneous intelligence is an interesting case in which a man, who was a prisoner at Brisbane, and who appeared to be labouring under religious delusion, refused food for forty days, but recovered after that time, and in the Correspondence column there is a very temperate and well-written letter on the subject of the

"Social Evil," the writer showing that little good is to be expected from legislation on the subject, but much from the inculcation of sound moral doctrines into the minds of the young of both sexes. On the whole, this Journal seems to thrive and to improve under the auspices of its accomplished Editor.

THE 'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

Aneurism of the Wrist; Ligature of the Brachial Artery.—Malignant Anthrax cured by Cauterisation.—Acute Orchitis; Injections of Tincture of Iodine—Nasal Polypus.

We recently published a case of hæmorrhage in the palm of the hand, in which Mr. Duprez, a Belgian military surgeon, resorted with success to ligature of the radial and ulnar arteries at the wrist, and we stated at the time that, under similar circumstances, Mr. Jarjavay had deemed it safer to secure at once the brachial artery. In general, we believe that the plan adopted by Mr. Duprez is the best, but the surgeon must not lose sight of the fact that the ligature of the arteries at the wrist may be insufficient and that it may be necessary to take up the brachial artery. A case in point recently occurred in the wards of Professor Jobert at the Hotel Dieu.

In this instance it was not primary hæmorrhage, but traumatic aneurism of the ulnar, consequent on a wound of the artery with a fragment of glass, which called for surgical interposition. Mr. Jobert kindly permitted us to examine his patient, a wine merchant's servant, aged twenty-four, who, in the discharge of his duties, cut his arm with a broken bottle. At first the hæmorrhage seems to have been insignificant, but in the course of a few days, a small fluctuant and throbbing tumour made its appearance in the wounded part, presenting all the characteristics of traumatic aneurism. The man was admitted into hospital on the 24th of September, 1863, and for a month pressure was applied perseveringly, but without any benefit. On the 4th, 6th, 11th, and 13th of November, Mr. Jobert performed coagulating injections with the sesquichloride of iron, at 30°, areom., but as hæmorrhage again occurred on the 20th of the month, the Professor secured the radial artery, an operation which did not succeed in intercepting the circulation in the tumour. On the 22nd he applied a ligature with the same ill-success over the ulnar artery, and hæmorrhage recurring with increased frequency, Mr. Jobert was at last obliged to take up the brachial artery. This operation effected the desired result, and the patient is now on the eve of being discharged from the wards.

This case is not destitute of practical interest, and shows that even performed by the most dexterous hands, pressure and coagulating injections may fail in justifying the expectations legitimately founded on their occasional success. We learn, in addition, that the numerous anastomotic branches which establish the communication between the radial and ulnar arteries, and more particularly the preternatural development of the inter-osseous branch may suffice to cause a return of the blood through the inferior part of the injured blood-vessel even after the two main branches have been secured with a ligature.

A costermonger, aged fifty-three, is at present undergoing treatment in Mr. Jobert's wards for malignant anthrax. We take this opportunity of referring our readers to a lecture delivered by the Professor, on the benignant form of the disease. At this period, 1858, he explicitly stated that, in his opinion, even the mildest manifestations of the affection were connected with general disturbance of the system. "If the distinctive character of carbuncle be attentively watched," said he, "it will always be observed to have a tendency to spread in the cellular tissue, and to extend towards deep-seated organs. With regard to the general condition of the patient, the blood will invariably be found to have undergone remarkable modifications in its principal constituents, fibrin and corpuscles, consequent upon the deleterious influence of physical or mental distress, insufficient diet, great fatigue, or unwholesome food. A tree withers because the soil is poor; the human textures likewise become diseased when the nutrimental fluids are adulterated; a peculiar noxious atmospherical influence also predisposes the skin to become the seat, not of genuine inflammation, but of a special mode of inflammatory action, such as erysipelas, zona, boils or carbuncles, or, under different circumstances, numerous abscesses are observed without any putrid infection being clearly ascertained to exist."

Mr. Jobert's remarks on benignant carbuncle, apply with even greater force to the pathology of malignant anthrax, which according to Mr. Bourgeois, of Etampes, differs from *charbon*, or malignant pustule, merely by the fact that it is preceded by a pecular feverish excitement, of which the carbuncle would seem to be a critical manifestation, whereas the general symptoms are secondary in malignant pustule. The two diseases may, however, be discriminated by other signs which it is not our purpose to dwell on at present, but we merely alluded to pustula maligna because the local treatment of both affections should be conducted on the same principles. In malignant anthrax debilitating causes are concerned in the production of the disease, and Mr. Jobert opines that residence in a damp habitation greatly promotes its development. He further remarks that animals fed in marshy pastures are more liable to carbuncle than those which graze on dry hills, and in this respect the pathogenic influence is the same on the human subject.

A partial illustration of this view may be derived from the history of the patient at present lying in the wards of the Hotel Dieu. The man was in the enjoyment of perfect health when the disease set in; his diet was nutritious, and he had undergone no unusual fatigue, but he resided in a damp apartment situated on the ground-floor. After a few days discomfort, he experienced pain in the right lumbar region, and after his admission into the wards, a tumour was discovered lying at the side of the vertebral column, resting on a broad, ill-circumscribed, and dusky coloured basis, and black at its centre, from which escaped a serous liquid. The intense pain and the feverishness usually concomitant with benignant carbuncle were not present. The disease was not in this case the result of the inflammation of the cellular tissue included in the fibrous areolæ of the derm, as a protection to the capillaries and nerves which run from the inferior to the superior surface of the latter; malignant anthrax occupies the cellular structures situated beneath the skin, and is an affection of a putrid nature, which runs a peculiar course, and requires something beyond the cruciform incision appropriate in cases of common carbuncle.

Incision would here almost infallibly be followed by hæmorrhage, which, however trifling in amount, might, on account of the low state of the system, give rise to considerable aggravation of the symptoms. Mr. Jobert, therefore, does not resort, under the circumstances, to the use of the knife. In the case under consideration, he transfixed the tumour on two successive days with troches of chloride of zinc. This operation was instituted on the 6th, and repeated on the 7th of December. The eschar was detached on the 14th, and from this date healthy granulation set in, and under the influence of tonics and generous diet, a complete cure soon followed, without the loss of a single drop of blood.

We have more than once alluded to the good effects of the iodine injection in acute orchitis. We again revert to this innocuous and efficient method of treatment, because it has now received the sanction of experience, and not only appears to promote the cure, but promptly relieves the pain.

This circumstance was peculiarly conspicuous in the case of a man, aged thirty-five, who was admitted into Mr. Jobert's wards on the 30th of November, for the treatment of orchitis which had supervened three days after the disappearance of a gonorrhœal discharge. The right testis was affected; Mr. Jobert inserted the trochar obliquely

into the tunica vaginalis, a few drops of fluid escaped, and the operator injected a small quantity of tincture of iodine. All pain promptly ceased, a warm bath and two saline aperients were prescribed, and the man is now retained in hospital but for the treatment of the gonorrhœa which has returned.

To relieve the sufferings of the patient is assuredly an important result; but the chief merit of the method consists in the prevention of the protracted induration of the epidydimis observable in cases treated on a different plan, and which interferes with the healthy performance of the functions of the organ.

We may add to the above particulars of Mr. Jobert's practice, supplied by Mr. T. Lucas Championnière, a prescription of the same professor in the case of a girl affected with nasal polypus.

1. To sniff each morning a pinch of the following powder:—

℞ Pulv. Tragacanthæ, ʒs.;
Aluminus pulv. gr. v.;
Zinci sulphatis, gr. iij.
M.

2. To inhale twice a day elder flower water.
3. To take every morning two table spoonsful of—

℞ Vini cinchonæ, ʒviij.;
Ferri sesquicarbonatis, ʒss.

Mr. Jobert opines that recently developed polypi may thus be destroyed in lymphatic subjects without operation. But even after the latter has been performed, the same remedies, both local and internal, will be found useful in preventing a relapse.

Strophulus, or Tooth-Rash. Pruriginous Strophulus.

No disease is more common or less known than strophulus, of which Mr. Hardy describes two varieties, the simple and the pruriginous form.

Simple strophulus is frequent in children at the period of teething, and affects more especially the face; the eruption consists of red or whitish papulæ, slightly acuminated, and sometimes complicated by the presence of erythema. This is an unimportant complaint, which requires interference only when it is attended with sufficient local irritation, to oblige the infant to scratch the affected part, which induces oozing of a serous fluid, and the formation of yellowish scabs. In this case, Mr. Hardy prescribes diluents, baths, and starch, or lycopodium powder externally. If necessary laxatives may also be exhibited.

Pruriginous strophulus, which in Mr. Bazin's opinion is one of the manifestations of scrofula, is more interesting to the pathologist, and Mr. Hardy conceives it to be distinct in its nature from common tooth-rash, and often mistaken for prurigo and scabies.

The eruption is not confined to the face, but extends to the entire body, occupying more frequently the arms, where the papules, whether red or colourless, occasion an irritation which increases in the evening, and deprives the patient of his natural rest. Mr. Hardy lays much stress on what he views as the pathognomonic character of pruriginous strophulus, viz., the simultaneous presence of the peculiar lichen, together with that of pimples tipped with black, which belong to the order prurigo. Between the latter eruption and pruriginous strophulus the discrimination is easy; but even experienced practitioners have mistaken at first sight the latter for scabies. In both affections the same complications, prurigo and ecthyma, are met with; and in addition, the local irritation is as great in one as in the other, and gives rise to violent scratching. One circumstance, however, establishes the difference, or at least supplies strong presumptive evidence in favour of strophulus, namely, the existence of papulæ on the face. In itch this seldom occurs, but in strophulus the rash is very generally observed on this part of the skin. Scabies, it is true, is not unfrequently accompanied by other eruptions, but they are to be found on the abdomen or the inner surface of the thighs (prurigo), or on the nates (ecthyma). These signs, confirmed by the discovery of the sulci of the acarus, will remove all doubt as to the true nature of the case.

Mr. Tranquebalme, a pupil of Mr. Hardy, records in his thesis upwards of sixty cases, which show that strophulus seldom appears after adolescence. The professor himself opines that it is a disease caused by poverty of blood, but he does not, like Mr. Bazin, connect it with the scrofulous diathesis.

According to Mr. Hardy, strophulus is not a contagious affection.

The gravity of the disease consists in its tendency to relapse if the patient does not alter the hygienic conditions which give rise to it. The adulterated blood must be reconstituted, and the deleterious influences which unfavourably modified its component parts must be removed. It is therefore necessary to recommend change of residence, country air, and healthy exercise. If these, the most efficient measures, cannot be complied with, chalybeates, bark, and cod-liver oil, should be prescribed; the local treatment should consist in alkaline or sulphurous baths, and as a sedative of the very distressing local irritation, the part affected should be dusted with the following powder, which Mr. Hardy also employs in zona:

℞ Pulveris amyli, ʒiij.;
Zinci oxydi, ʒj. M.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

SIR,—I shall feel obliged for space for the annexed letter, which will inform the Poor-law Medical Officers that the Select Committee on Poor Relief have been re-appointed, and now I trust we shall have such resolutions passed as will induce Parliament to amend the laws relating to the Medical relief of the poor. Since last July I have only received the following subscriptions:—W. Smith, Bromsgrove, 5s.; C. C. Claremont, St. Pancras, 10s. 6d.; W. H. Pilkington, Blackburn, 1*l.*; Medical Officers, Rotherham, 1*l.* I need scarcely say that, having already expended over 20*l.* more than I have received, it cannot be expected of me to take any very active measures unless the Poor-law Medical Officers will come forward in the same liberal manner which they did some three or four years since. The Select Committee must, I feel sure, recommend something, but a mere recommendation will do nothing, unless we place ourselves in a position to compel its being carried out. You are probably aware that a milk and water superannuation bill has been put in circulation amongst the guardians by the Poor-law Board, and although it is only a permissive and not a compulsory measure, the guardians have in many unions objected to it, and so they will to any Bill that may be sent them; therefore, if the Poor-law Board desire to shelve a measure they have only to send it to the guardians for their opinion, and the affair is at once settled. The registrars throughout the kingdom have lately been in correspondence, and are endeavouring to obtain one shilling for each vaccination registration instead of the threepence now paid.

I wish them success, but I think when their measure comes forward we ought to get a clause inserted that our 1s. 6d. for vaccination should be increased, but unless we have a fund in hand of at least 100*l.* we can do nothing.

I am, &c., RICHARD GRIFFIN.

12 Royal Terrace, Weymouth,
23rd February, 1864.

12 Royal Terrace. Weymouth,
22nd February, 1864.

SIR,—I have the honour to forward to you by railway, evidence on the Medical relief of the poor, supported by an extensive series of tables which I respectively beg you will lay before the Select Committee on Poor Relief, which I perceive by the newspapers has been re-appointed. The evidence which I now submit to the notice of the committee, will, I feel confident, convince them that the evidence laid by me before them in 1861, is substantially correct, and that the evidence of Mr. Cane, in April, 1862,

in respect thereof is most incorrect, and tends to conclusions which, if uncontradicted, must mislead the committee and prevent them coming to a right decision on the question. I will give you an instance of the errors committed by Mr. Cane, who says "in 1858 there were 3,307 Medical Officers, and in 1861, 3,479," whereas at this moment there are not more than 3,102, or thereabouts, Mr. Cane having confounded the Medical districts and appointments, with officers. Mr. Cane says (3887) "in 1840 the Medical relief was 151,781*l.*, and in 1861, 238,222*l.*," (3,839). "It has been constantly and largely increasing up to last year," but he omits to inform the committee that since 1840 the area and population of the places brought into account has largely increased, and that in reality the main increase in the payment arises from the formation of new unions and the addition of extra parochial places to the old unions, parishes, and incorporations. Mr. Cane has thought fit to impugn my figures, but I can assure the committee they are in the main correct. A few places, no doubt, are erroneously spelt, Retford for instance, which Mr. Cane has most unfairly commented on, although he must have known the place referred to was Thetford, for had I meant Retford, I should have called it by its right name, East Retford, and not have dropped part of the name as Mr. Cane has done.

These quotations will prove how little his evidence is to be relied on; I, therefore, respectfully trust the Select Committee will admit my evidence in refutation of that of Mr. Cane's, not only in justice to myself, but to the large body of Medical Officers I have the honour to represent, and I may add, in justice to the poor, for I feel confident that, if the views advocated by me be fairly carried out, much good will accrue to the poor, and ultimate benefit to the ratepayers. There is one point I wish should be brought before the committee, which is the establishment of dispensaries in all populous places, and that the drugs should be found by the Poor-law Board, and in thinly-populated places, where dispensaries could not be established, an allowance, say 2s. per case, should be paid to the Medical Officers for drugs. In payment, I would advise that the money now voted by parliament for half the salaries, should be applied to this purpose; the guardians being compelled to pay a sum not less than 2s. per case in towns as salary, with mileage in country places.

I am, &., RICHARD GRIFFIN.

The Right Hon. C. P. Villiers, M P., Chairman
Select Committee Poor Relief.

MERCURY IN SYPHILIS.

To the Editor of the Medical Circular.

Sir,—As I have observed by the MEDICAL CIRCULAR, that a paper has been read lately at the Harveian Society, by Dr. Charles Drysdale, entitled "Evidence against the Internal use of Mercury in Syphilis, and other Diseases;" and as the subject is one of most vital importance, not only to the Medical Profession, but to the public generally, I trust you will be kind enough to allow me, through the medium of your most useful and impartial Journal, to make a few remarks regarding it, more especially as I am opposed to the views and opinions of Dr. Drysdale, as set forth in his paper; and although Dr. Drysdale may have been able to occupy the attention of the Harveian Society for two evenings with the reading of this paper, and that fifteen gentlemen had spoken upon it, during the debate, as the Doctor has informed us, still that is no reason that the public or the Profession should be led away by it. For what can the public think now, or what can the Profession say for itself, if Dr. Drysdale's paper is to be tolerated by a single member? But for Dr. Drysdale to stand up, and tell the whole Profession that all the Medical practice of both the past and present centuries was, not only useless and nugatory, but actually homicidal in its results, is to say the least of it, rather a strong statement. But since Dr. Drysdale has taken upon himself to condemn the use of mercury in every kind of disease, what kind of substitute does he propose to introduce in its stead? Is it possible, Sir, that he has nothing to give us, but some farrago or ideal goddess of his, called "Hygiene," and some sort of external application, and Epsom salts. This is the sum total, of all that we can find in Dr. Drysdale's paper.

Now, it has been asked, what is the natural history of syphilis if left to itself without any treatment? Yet, I should think it far more consistent, under present circumstances, to ask first, what is the natural history, or the real effects of mercury on the animal or human system, when it has been taken during health, or when the system is labouring under disease? But while Dr. Drysdale and Dr. Graily Hewitt, Dr. Ballard, and also Dr. Hughes Bennett, have all informed us that mercury is not only useless, but actually injurious when administered in cases of acute hydrocephalus, puerperal peritonitis, and certain other acute and inflammatory diseases, still they have not, one of them, as yet, endeavoured to inform us why or how it is that mercury acts in this manner in almost all such cases? Now, far be it from me to say, that mercury, under the form of both calomel and blue-pill, is not a most dangerous drug to tamper with, or that it has not been often grossly abused in the hands of the ignorant; still we must all own and acknowledge that it is a useful remedy in many cases. But as mercury is known to act very differently on different constitutions, it ought therefore to be used with very great caution in some diseases, and most particularly so when the person is known to be the least tainted with the scrofulous diathesis. But the chief reason, in my humble opinion, why mercury acts so injuriously in acute hydrocephalus and other inflammatory diseases, is because it always acts as a kind of stimulant in the first instance, and must, therefore, only tend to increase and heighten the violent fever that is already going on;—yes, and may drive or force on this acute disease to a suppurative or, perhaps, fatal termination, and that more particularly when such extremely delicate organs as the membranes of the brain are the parts engaged. But I am surprised that Dr. Drysdale should begin now to tell us that mercury is of no use whatever in any disease, and boldly assert all this, by merely quoting and referring us to a whole catalogue of foreign and unknown names, and to the opinions of other Medical men, without having shown us that he has ever made any experiment of his own, so as to be able to prove his case is rather too much.

Yes, to a whole host of names, English, Irish, German, French, and even of Medical gentlemen in America he refers us,—not to speak of the names of Dr. Hughes Bennett and Mr. Allingham—but why Dr. Drysdale does quote to us so often the name of Dr. Hughes Bennett is more than I can understand. But the last and greatest cut of all is, when Dr. Drysdale takes on himself to advise all your great London Medical men to go back to school again, either to Mr. Lane, or some other experienced gentleman like him, to see if he can now unteach or expunge from their minds in any way the erroneous and homicidal doctrine, which they all seem to have so largely imbibed from the teachings of the late Mr. John Hunter, and other mercurial gentlemen since his day. So, is it possible then that we can find nothing of any use under the sun to cure any sore or disease whatever, as far, at least, as Dr. Drysdale would try to make us believe, unless it be the charms of the undefined and wonderful goddess called "Hygiene," with some external applications and Epsom salts.

Such is the end and aim of Dr. Drysdale's learned and voluminous paper. Such the value, and such the whole amount of all the accurate and exact statistics with which he has occupied the time and attention of the Harveian Society.

I am, &c., N. MCGREEVY, L.R.C.S.E.
Lurgan, Feb. 18, 1864. and L.S.A., &c.

ALLOWANCE OF FORAGE TO ARMY MEDICAL OFFICERS.—By a Warrant lately issued from the War Office, all Medical officers above the rank of Assistant-Surgeon will be henceforth entitled to horse forage, or an equivalent allowance, according to relative rank. An Assistant-Surgeon will be allowed forage for a horse if his duty oblige him to keep one. This is a restoration of one of the clauses of the Medical Warrant of 1858.

LEGAL INTELLIGENCE.

VICE-CHANCELLORS' COURT. FEB. 25.

(Before Vice-Chancellor SIR W. P. WOOD.)

EX PARTE THE GOVERNORS OF ST. THOMAS'S HOSPITAL.

This case comes before the Court by adjournment from chambers, for the purpose of obtaining the sanction of the Court to a conditional contract for the purchase by the governors of St. Thomas's Hospital from the Metropolitan Board of Works of certain lands on the river side at Stangate (abutting on the south end of Westminster-bridge) as a site for the new hospital. The present proceedings arise out of the necessity of providing a new site for St. Thomas's Hospital, the site of the original hospital, near London-bridge, having been taken by the Charing-cross Railway at a sum fixed by arbitration at 296,000*l.*, and now invested in 317,409*l.* 11s. 7d. Bank Annuities. By an order of this Court made in May, 1862, the governors of the hospital were authorized to apply to Parliament for an Act for the purpose of enabling them to sell to the Charing-cross Railway Company the fee-simple of the late hospital, and to build and re-establish a new hospital, and to provide for the temporary accommodation in the meantime for the patients thereof, and for other purposes connected with the administration of the charity, &c. The draught of the Bill for this Act was approved by the Vice-Chancellor, and the Act, (the short title of which is "the St. Thomas's Hospital Act, 1862") received the Royal assent in August, 1862. This Act enabled (section 2) the governors "to purchase by agreement any lands which may be approved by the Court of Chancery on a summary application at the chambers of one of the judges of that court, of which application the Attorney-General shall have notice, for a new site for the said hospital, or of buildings to be used for any of the same purposes as the present hospital, or which may be convenient to be held, with any such site, not exceeding in the whole 50 acres." The governors were alse authorized by the Act to provide temporary accommodation for the patients. This temporary accommodation had, with the sanction of this Court, been provided in the Surrey-gardens. Various sites were proposed to the governors for their new hospital during the course of last year, and, as it will be remembered, the question was from time to time discussed in our columns by the advocates of the different schemes, which included a removal to the Surrey-hills, far away from the metropolis. The proposed sites became at length practically reduced by elimination to four:—1. The Stangate site, between Lambeth Palace and Westminster-bridge, immediately fronting the river, comprising about 8½ acres; 2. The site of Bethlehem Hospital in St. George's fields, comprising 11 acres; 3. The Surrey gardens, of about 14½ acres; 4. A tract of ground, partially built upon, at the back of Newington Church. Considerable negotiations took place between February and July last in reference to the purchase of Bethlehem Hospital, the terms proposed by the governors of that institution being that the governors of St. Thomas's Hospital should either provide for them a new Bedlam equal in every respect to the present, or else pay them 200,000*l.* for the purchase of the site of the present building. These terms were not accepted by the governors of St. Thomas's Hospital, and the negotiation went off. In the meantime the governors were offered the site at Stangate for 95,000*l.* by the Metropolitan Board of Works. The Medical officers of the hospital reported strongly in favour of this situation as a site for the new hospital, and on the 19th of November, 1863, the governors entered into a conditional contract with the Metropolitan Board of Works for the purchase. A summons was taken out in chambers for the purpose of obtaining the Vice-Chancellor's sanction (as required by the Act of 1862) to this contract, and the question now came before the Court by adjournment.

The arguments were continued on Saturday, and at their conclusion the Vice-Chancellor in the course of a long and elaborate judgment, said that it was important to bear in mind that the question was not as to selling the old hospital, but as to the application of the purchase-money in providing a new site. The form and scope of the Act of 1782 was clearly to vest in the governing body the power and control which up to that time had been assumed by them. The acting governors were invested with powers over the real estate of the charity, and the corporation could neither dispose of the property adverse to the views of the governors, nor even without their consent apply for an Act of Parliament to authorise such disposal. With respect to the Act of 1862, the corporation, if they had been so minded, might then have raised their present contention, and objected to the sale of the real estates for which it was proposed to obtain Parliamentary authority. Not having done so, they must be taken to have ratified the sale as a dealing with the property by the governing body, authorised by the Act of 1782, in the best possible way. The sale which had been thus ratified and sanctioned as a proper sale under the Act of 1782 had been effected, and the money was ready to be laid out in the purchase of a fresh site. He was clearly of opinion, therefore, that the corporation had not established their claim to be the body in which alone the power of choosing a new site was vested, and that, on this ground, he ought not to interfere with the acting governors, and withhold his sanction to the site chosen by them. The remaining question then was whether with all the evidence that had been adduced in favour of the Surrey Gardens he ought to hesitate in confirming the arrangement made by the governors. The real question was between the Surrey Gardens and Stangate, for the much larger price asked for Bethlehem, without any corresponding advantages, put that site out of consideration. The Act of 1862 gave a very wide discretion as to situation. In fact, the choice was clearly not thereby confined to the metropolis proper. At the same time it was intended that all persons interested should have the right of raising objections to the proposed site, and of being heard in the matter. No one, therefore, could complain of the corporation appearing upon the present application in their corporate capacity. The Legislature, though it gave the governors a wide scope within which to make their choice, restricted that choice by requiring that any site which the governors might select for the erection of a new hospital should be subject to the approval of the Court of Chancery. But the Court was not thereby vested with an arbitrary power of rejecting any site that the governors might submit for its approval, and taking upon itself to choose a fresh site. Unless it could be shown that the governors were influenced by improper motives in making their selection, the Court ought not to withhold its sanction. No such improper motives had been shown or even suggested, nor could he come to the conclusion that the governors had not carefully and after much deliberation decided upon the Stangate site. With the unanimous consent of the Grand Committee and the unanimous consent of their medical officers they had come to the conclusion that Stangate would be a proper situation for the new hospital. It was not, therefore, the function of the court to interfere with a choice thus deliberately and unanimously made, when no improper motive or influence could be shown to have prevailed. His Honour then proceeded to consider the evidence and the objections raised to Stangate, and came to the conclusion that the objections raised were not sufficient to show that that site ought not to be sanctioned. The Milbank Penitentiary, immediately opposite to the bone nuisance, and on the banks of the Thames, showed by its healthy state the results that might be obtained in such a situation by good management. The death-rate proved that Stangate was rather more healthy than other parts of the metropolis. The situation was very accessible, and would have the large river area in front, which could never be built over. Some disadvantages, no doubt, there must be in any situation in the metropolis itself, but those disadvantages were by no means prominent at Stangate. The objection to the river situation was also answered by the success of the Hôtel Dieu on the Banks of the Seine, one of the largest hospitals in Europe. It appeared upon the evidence that, although a new model hospital had been recently established in Paris

with a much larger area around it, the Hôtel Dieu had still retained its rank and success. No doubt, as to size, cheapness, proximity to the original hospital, and more immediate occupation, there was evidence in favour of the Surrey Gardens; but unless persuaded that the Stangate site was absolutely improper, and that there were overwhelming reasons for preferring the Surrey gardens, he ought not to disturb the deliberate choice of the governors. He was not so persuaded, and the choice of the Stangate site would therefore be sanctioned by the Court.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 11th ult.:—Henry Osborn Fawcett Butcher, Ware, Herts.; Jabez Bunting Jackson, Leicester; William Burt Shorto, Charing cross hospital.

The following gentleman on the same day passed his first examination:—Frederick John Burge, King's College hospital.

A certificate to practise was received on the 18th ult., by the gentleman whose name is subjoined:—Edward Carpenter, St. Thomas's hospital.

The following gentlemen also on the same day passed their first examination:—William Bell, King's College; Edmund Farrington Boult, King's College; Griffith Griffith, University College; Alex. Clement Rayner, Charing cross hospital; George William Rigden, University College; Francis Henry Wickham Taylor, St. Thomas's hospital; M. S. W. Wilson, King's College.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their first professional examinations during the recent sittings of the Examiners:—William Lawton Eames, Cork; James Hogg, Edinburgh; Joseph Jackson, Cumberland; Thomas Macdonald, Ross-shire; John N. O'Keeffe, co. Kerry; James Simpson, Cumberland; Thomas Simpson, Yorkshire.

The following gentlemen passed their final examinations, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—James Hinds, Notts; Patrick Callan Horan, co. Cavan; Joseph Lindsay Kingston, co. Cork; Latham Blacker M'Culloch, Drogheda.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examinations during the recent sittings of the Examiners:—Robert Anderson, Haddingtonshire; James Ingram, Orkney.

The following gentlemen passed their final examinations and obtained the diploma of the College:—Robert Pearson Dunbar, Perthshire; James Godfrey, Glasgow; Heinrich Frederik Lawatz Melladew, London; John Middleton, Glasgow; Frederick Montizambert, Quebec; William John Taggart, Antrim.

THE ROYAL POLYTECHNIC INSTITUTION.—The report of the indefatigable manager of the Royal Polytechnic Institution, Professor Pepper, just presented to the shareholders, shows that the receipts for the past year were 13,000*l.* against the receipts of the Exhibition year, which were only 10,000*l.* The directors have paid the highest compliments to the Professor for his exertions on behalf of this institution, and, under the patronage of the Prince of Wales, they augur a prosperous future. We regret that the proposition of one of the shareholders to present Mr. Pepper with a gratuity of 1,000*l.* was not carried. The prosperity of the institution is so completely identified with his services, that not to acknowledge them in a handsome manner can only be regarded as a false economy.

CONSUMPTION OF VICHY WATER.—The consumption of this alkaline water has assumed in France, and especially in Paris, gigantic proportions. In 1863, there were despatched from Vichy 1,460,000 bottles; and 180,000 baths were administered. Paris alone received 900,000 bottles. Since the 18th January, the public has been allowed free access to these as to the other Medical waters in France, without the intervention of Medical Inspectors of Mineral Waters heretofore necessary.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAR. 2. — *Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Croonian Lectures: Dr. Basham, "On Dropsy: its Significance as a Symptom in Renal, Cardiac, and Hepatic Diseases;" Obstetrical Society of London, 8 p.m.—"Cases of Ovariotomy," by Dr. Tyler Smith; and Papers by Mr. Squire and others.

THURSDAY, MAR. 3. — *Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Marshall, "On Animal Life," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia;" Chemical Society, 8 p.m.—Professor Abel, "On the Non-Metallic Impurities of Refined Copper:" Harveian Society, 8 p.m.—Mr. Weeden Cooke, "On the Tumours affecting the Female Breast."

FRIDAY, MAR. 4.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Lumleian Lectures: Dr. Barclay, "Fallacies in the Application of the Inductive Method of Reasoning to the Science of Medicine;', Royal Institution, 8 p.m.—Professor Stokes, "On the Discrimination of Organic Bodies."

SATURDAY, MAR. 5.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, MAR. 7.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAR. 8.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On Paralysis, Neuralgia, and other Affections of the Nervous System, and their Successful Treatment by Galvanisation and Faradisation. By J. Althaus, M.D., &c. Third Edition. London: Trübner and Co., 60 Paternoster row, E.C.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

Mr. GRIFFIN'S letter has been received, and is inserted.

THE HARVEIAN SOCIETY.—The notice has been received.

THE ROYAL INSTITUTION.—The paper has been received.

PHARMACOPOLA.—The radical, as it is called, of benzoic acid and of the oil of bitter almonds, is the same—namely, the hypothetical substance, benzule. Benzoic acid may be obtained by exposing oil of bitter almonds for a long period to atmospheric air, by which oxidation is effected.

X. Y., *Manchester.*—A deed of apprenticeship is not absolutely necessary.

A NORTHERN.—The whole population of Scotland is about the same as that of the English Metropolis alone.

Mr. PEPPERCORN.—The letter has been received, and will appear next week.

Mr. W. B. MURRAY.—The Report has been received, but is unavoidably postponed till next week.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By Robert Hunter Semple, M.D.,
Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 80.)

The *cause* of the sounds of the heart is a subject still involved in considerable obscurity, not so much because there are no phenomena to account for them, as because so many concurrent circumstances attend the sounds that it is not easy to determine which are the most efficient in their production. It is the most difficult problem to account for the *first* sound, owing to the reason just mentioned; to explain the *second* is more easy, because the attendant circumstances are fewer in number.

The order of succession in which the functions of the heart take place is as follows:—The cavities having received from the venæ cavæ and the pulmonary veins the necessary supply of blood, the auricles suddenly contract, and their contraction is immediately followed by the contraction of the ventricles, and the apex of the heart is tilted forwards against the walls of the chest. At the same moment, the auriculo-ventricular valves are closed in order to prevent the regurgitation of blood into the auricles, and the current is, therefore, driven towards the aorta and pulmonary artery, the semilunar valves at the origin of these vessels being raised and thrown back against the arterial walls. During these operations the first sound of the heart is produced.

Immediately after the contraction of the ventricles, follows their relaxation and dilatation, and the semilunar valves of the aorta and the pulmonary artery suddenly close, and prevent the regurgitation of blood into the right and left ventricles, and at this period the second sound of the heart is heard.

Before the ventricles are quite empty, the blood from the system and from the lungs is filling the auricles, and flowing in by the systemic and pulmonary veins, and passes through the mitral and tricuspid valves. Almost all this takes place during the period of silence which follows the second sound of the heart, and at the end of this period of silence the contraction of the auricles takes place.

From a consideration of these facts, the cause of the sounds has been sought in some of the actions which occur, or it has been attributed to their joint operation, and some theories have been rejected as being inconsistent with the known sequence of cardiac functions. Thus Laennec attributed the first sound to the contraction of the ventricles, and the second to the contraction of the auricles, but as the contraction of the auricles is proved to be coincident with *the period of silence*, and to take place immediately *before* and not *after* the first sound, it is impossible that Laennec's explanation can be the true one.

Some of the causes of the sounds are traceable to the heart itself, some to the passage of the blood, some to the relations existing between the heart and surrounding parts, and the following analysis abbreviated from the last edition of Barth and Roger's 'Traité Pratique d'Auscultation,' will exhibit the variety of opinions which have been entertained on this subject.

Corrigan attributed the first sound to the impulse of the blood against the walls of the ventricles during the diastole, and the second sound to the reciprocal impulse of the internal surface of the opposite walls of the ventricles during the systole. The objection to this theory is that there is no proof that the ventricles are ever completely emptied of blood. Hope, in 1831, attributed the first sound to the collision of the molecules of the blood during the systole, and the second to the same kind of collision during the diastole, but in 1839 he came much nearer to the true explanation by referring the first sound to the tension of the valves, the sound of muscular extension, and the rotatory sound during the systole, and the second sound to the closure of the aortic valves during the diastole. Majendie explained the first sound by the impulse of the apex of the heart against the chest at the moment of the systole; and the second by the impulse of the anterior surface at the heart during the diastole. Bouillaud attributed the first sound to the sudden elevation and impulse of the auriculo ventricular valves, and sudden depression of the semilunar valves during the systole, and the second to the elevation of the semilunar valves and the meeting of their opposite surfaces, and sudden depression of the auriculo-ventricular valves during the diastole. Skoda, whose notions on this and other auscultatory phenomena are eccentric, although highly ingenious, supposes that the first and second sounds of the heart are produced simultaneously in both ventricles and in the aorta and pulmonary artery, both of them in each of these four points at the same time. He attributes the sounds to various causes, as the impulse of the blood against the valves, the impulse of the apex of the heart against the walls of the chest, the impulse of the blood against the walls of the aorta and pulmonary artery, the retrograde impulse of the arterial blood against the semilunar valves, all these causes acting together, although the sounds are heard consecutively. Dr. C. J. B. Williams attributes the first sound to the muscular contraction of the ventricles during the systole, and the second to the retrograde impulse of the arterial currents against the semilunar valves during the diastole. The Committee of Dublin, which met for the determination of this question in 1835, under the presidency of Dr. Macartney, confirmed the views of Dr. Williams, and referred the first sound to the muscular contraction and the friction of the blood against the walls of the ventricles during the systole; and the second to the tension of the semilunar valves and the retrograde impulse of the arterial columns during the diastole. As the Dublin committee did not consider all the questions proposed to be definitely settled, a committe was formed in London, which confirmed the previous results. This committee found that the first sound was due to the sudden muscular tension of the ventricles during the systole and the impulse of the heart against the chest; and the second to the sudden closure of the semilunar valves by the arterial columns.

It is now generally admitted that the first sound is compound in its nature, being produced by a number of causes. The circumstances which accompany this sound are the muscular contraction of the ventricles, the impulse of the heart against the thorax, the sudden elevation of the semilunar valves against the walls of the arteries, the sudden tension of the mitral and tricuspid valves, the collision of the blood against the valves, the reciprocal influence of their corresponding surfaces, the molecular collision of the blood compressed and propelled towards the orifices, and the friction of the blood against the walls of the ventricles.

The efficient causes of the first sound seem to be—1. The muscular contraction of the ventricles; for the sound may be perceived, although less distinctly, when the heart has been removed from the body, and emptied of its blood, as was proved by the London committee. 2. The impulse of the apex of the heart against the chest; for when the parietes of the chest, against which the apex usually beats, were removed, the sound was very much diminished in intensity, although not extinguished. 3. The tension of the auriculo-ventricular valves; inferred to be a cause of the sound from their analogy with the semilunar valves, although their closure is not nearly so sudden as that of the latter. 4. The impulse given by the blood to the lower surface of the semilunar valves and to the base of the arterial columns

of the aorta and pulmonary artery; a view supported by experiments made upon tubes out of the body, and by comparing the intensity of the sound at the base of the heart where it was loudest, and over the region of the auriculo-ventricular valves where it was inaudible.

The principal phenomena which accompany the second sound are the dilatation of the ventricles and the collision of the blood which flows into their cavities, the sudden depression of the auriculo-ventricular valves, the sudden tension of the semilunar valves, and the retrograde impulse on their upper surfaces of the columns of blood thrown into the aorta and the pulmonary artery. It is now generally admitted that the cause of the second sound is the sudden closure of the semilunar valves of the aorta and pulmonary artery, for in the experiments made upon the lower animals, it was found that when the valve was held back against the side of the artery, by a curved needle, the sound was entirely absent.

(To be continued.)

HOSPITAL REPORTS.

ABSTRACT OF A CASE IN WHICH AMAUROSIS SUPERVENED ON EIGHT SUCCESSIVE PARTURIENT PERIODS.

This case occurred in the practice of Dr. Eastlake, Physician to the British Lying-in Hospital and some time since was read by him before the London Obstetrical Society. It is as follows:—

The patient was thirty-four years of age, married, the wife of a painter, and the mother of nine children, with all of whom she had accomplished her full time; there had been no miscarriages, and all the labours were ascertained to have been natural; nor was there with each any loss of blood greater than usual; nay more, at the last the hæmorrhage was peculiarly slight.

The first accouchement was unattended by any untoward symptom, and convalescence was speedy; however, two or three days after the birth of her second child, she became suddenly and completely blind, as well as partially unconscious; when the consciousness was regained, the amaurosis still continued.

These conditions have now occurred after all her last eight labours, and on an average the defective vision persisted for three to five weeks.

The following was the state in which Dr. Eastlake found her on the occasion of his first visit, she having been then delivered three days:—Pulse rather weak, but no marked pallor in face, nor much general debility; intellect clear, though it had been aberrant on the previous day. There had been no ergot given at the time of her labour, nor was there suppression of the milk or of the lochia; no exhausting discharge had existed; indeed, all the functions were duly exercised except that of vision, which was so far in abeyance as to hinder even the perception of light.

The ophthalmoscope showed only contraction of the retinal arteries; no strabismus existed, nor could any deviation from the normal condition of the eye-ball be detected.

The treatment pursued was in accordance with the woman's general condition, liberal diet, bark, and mineral acids being allowed and administered, and with most felicitous results.

Dr. Eastlake remarked that none of the ordinary causes of this affection were demonstrable in the present instance, and that the lesion was most probably in direct relation with, and dependent upon, the puerperal condition. The case is replete with interest, inasmuch as it is unique. The author of the paper mentions that Beer reported in 1817 an instance of a patient in whom amaurosis took place at the commencement of pregnancy, but who was perfectly free from it after parturiency. Nausea or uncontrollable vomiting are sometimes found to be co-existent with this affection.

Dr. Eastlake quotes a case of Dr. Ramsbotham, which has been published in the 'Medical Times and Gazette,' as bearing upon the subject under consideration:—"The earlier months had passed over very well, but about six weeks before, the patient had begun to lose the sight of both eyes simultaneously, and continued to get worse by degrees until Dr. Ramsbotham's visit, when she was so completely blind that she could only just point out the situation of the window. She had not suffered any pain in the head, nor any unusual drowsiness; the recollection was perfect, and she was quite sensible; the pupils were much dilated, the right more so than the left; the pulse was quick and small.

"She was cupped, leeched, blistered, and slightly salivated without relief, and continued getting worse, until she could not distinguish the brightest sunshine. On the 23rd day she began to feel a tingling and numbness in the right arm and leg without any loss of power."

Apoplexy or convulsions were apprehended as likely to attack the patient at the time of her labour, so that after consultation with Dr. Blundell it was deemed advisable to continue the mercury, and to extract more blood by the application of leeches to the temples.

"The patient went into labour at mid-day of the 28th, and was delivered on the next day by craniotomy, owing to the pelvis being below the average; the child was putrid; no convulsions occurred, and as far as the labour was concerned, she went on exceedingly well, but the blindness, numbness, and tingling remained without diminution for ten days, after which time she began gradually to amend, so that in a month she could distinguish objects, and in six weeks she told me the hour of my watch, and on the 24th of August she went out of town very weak, but had completely recovered her sight. She had one child afterwards, without any return of the symptoms."

This case of Dr. Eastlake is of immense interest, especially to those who devote themselves to the study of the diseases of women.

The author of the paper refers to a form of amaurosis, commencing with the early stage of pregnancy, disappearing after parturition, and connected with nausea and uncontrollable vomiting, which has been described by Beer, who carefully teaches that it should be distinguished from amaurosis occurring in the latter months of gestation, and which is due to violent and continued congestion of the head, at the same time that the bowels are loaded with fæculent accumulations, constipation having been present for some time.

This affection of the vision is, we think, but one of the multiform varieties of paralysis, to which women are obnoxious during gestation, or after labour has been completed.

Dr. Dewees, in his work on 'Midwifery,' records two cases of convulsions, in which temporary blindness supervened.

Dr. Abercrombie says, when writing on 'Diseases of the Brain:'—"The whole phenomena of palsy do indeed bear evidence that certain cases of it depend upon a cause, which is of a temporary nature, and capable of being very speedily and entirely removed. In certain cases of palsy, we occasionally see the affection continue without any improvement for many weeks or months, and then, from some change which entirely eludes our observation, take a turn for the better, and entirely disappear."

Dr. Fleetwood Churchill, in his chapter on 'Paralysis Occurring during Gestation and in Childbed,' gives the following summary of inferences deduced by him after the examination of various author's works:—First, that hemiplegia, paraplegia, or partial paralysis, may occur previous to, during, or some time after labour; secondly, that by some, the paralysis in paraplegia, especially, is attributed

to pressure upon the muscles or nerves in prolonged labour; but this is also denied, as the same disease follows easy labour, or occurs after the lapse of some days; thirdly, paralysis may terminate convulsions or accompany them; fourthly, paralysis may be the consequence of organic disease, or of effusion into or upon the brain or spinal marrow; fifthly, paralysis may result from reflex action; sixthly, the palsy may depend upon temporary causes, and among such causes albuminuria may be included; seventh, hemiplegia may run on into apoplexy, or it may pass off in a few weeks, or sometimes more slowly. Paraplegia may leave a temporary or more permanent lameness: the local palsies—amaurosis, deafness, &c.—generally last but a moderate time; eighth, a nervous or hysterical paralysis may occur occasionally in the unimpregnated state, or during pregnancy, but it seldom continues after delivery."

We quote a case of amaurosis given by Dr. Lever, in the fifth volume of the 'Guy's Hospital Reports:'—"The patient, æt. thirty-one, had quickened with her fifth child, and being engaged in some plain needle-work, suddenly felt a peculiar sensation in the eye-balls, and found on opening the lids, that she could merely see the outline of objects, their centre being perfectly dark; the pupils large, contracted sluggishly upon the stimulus of light; the eyeballs seemed to have lost, in a measure, their mobility, and to be inordinately fixed; the eyelids altogether or nearly covered the globes, for if they were not protected, she complained of dryness and smarting in them. A week after delivery, an amendment was perceived, and the patient continued steadily to progress, till after the lapse of a few months the sight was perfectly restored."

Another case occurred in the practice of the same gentleman, and is likewise mentioned in the 'Reports:'—"The lady was about thirty years of age, highly sensitive, nearly eight months pregnant, and was suffering from perfect amaurosis in one eye; in the other, the loss of vision was not so complete.

"She had had two fits." Dr. Lever, by her appearance and her evidence, was induced to suspect the presence of albumen in the urine. On the application of the usual tests, this condition was found to exist. As the vision became more and more impaired, the operation for the induction of premature labour was resorted to, and the child was expelled still-born. Recovery quickly supervened.

In Dr. Crosse's 'Cases in Midwifery,' the following occurs:—"Mrs. C., her first pregnancy; under difficulties and depressed spirits; under thirty years of age; labour began with a convulsion; eyesight and sensibility lost; pupils greatly dilated; 'os' was much dilated; delivery effected by forceps.

"Bleeding and blistering being fully practised, the convulsion ceased; eyesight quite lost for several days, at length returned, and there was perfect recovery."

"I have no doubt," writes Dr. Churchill, in his new work on 'Diseases of Women,' page 917, "as Dr. Romberg has observed, that in a number of cases, especially those which occur during gestation, the palsy is due to a reflex action from some organ or structure in a morbid condition, and in which the nervous system seems to be merely the channel of transmission, offering no central disorganisation. In such cases the exciting cause may possibly be some injury or morbid condition of the generative organs, or, perhaps, merely a transient excitement, such as that of pregnancy. It is possible, also, that some of the instances occurring during gestation ought rather to be classed under the head of hysterical paralysis, as described by Drs. Laycock and Romberg, but it is not always easy to make the distinction."

These forms of paralysis or of the other nervous lesions, to which we have above made reference, are sometimes found coexistent with an anæmic condition of the system generally, and are occasioned either by the immediate blood deterioration acting injuriously on the great nervous centres, or on the entire nervous economy, or by the too highly-exalted excitability and sensibility of the nerves themselves.

"In the palsy of pregnant and puerperal women, whether partial or complete, whether local or general, we find that albuminuria may be a marked symptom; and if the observations are yet too few to draw any very positive conclusions, it is probably because our attention has not been drawn to the subject. And when, in addition, we find, as Dr. Lever states, that as the albumen diminishes the paralysis subsides, we can hardly doubt that there is some important connection between them."

There is no necessity for supposing the existence in these lesions under our consideration of that condition of the kidney to which we apply the term Morbus Brightii, since the presence of the albumen in such instances is "depending upon a cause which is of a temporary nature, and capable of being speedily and entirely removed."

To these remarks we append, inasmuch as they bear upon the subject, certain inferences of Dr. Leyfort, and which have been published by him in the 'Edinburgh Monthly Journal,' of February, 1854; they are these:—"First, albuminuria is not an essential accompaniment of normal, healthy pregnancy; second, the theory ascribing albuminuria to the pressure of the enlarged uterus on the renal vessels is inadmissible; third, when anasarca from Bright's disease occurs during pregnancy, the patients are seldom attacked by eclampsia; fourth, the albuminuria in cases of eclampsia *is occasioned by the interruption of the functions of the respiration and circulation by the attack;* fifth, in such cases the albuminuria terminates with the attack; sixth, albuminuria is not present in all cases of eclampsia; seventh, albumen is found in large quantities in the urine of epileptics immediately after an attack, but not invariably after every seizure or in every case of the disease; eight, provided there be no Bright's disease, this albuminuria among the epileptics ceases soon after the convulsions, and only returns after the next attack."

University Intelligence.—Cambridge, February 22, 1864. An examination for four minor scholarships will be held in Downing College on Monday, May 30 next, and the two following days, and will begin at 9 a.m. on Monday. The examination will be chiefly in classics and elementary mathematics, but some weight will be given to proficiency in French and German. Two additional papers will be set, one on moral philosophy in connection with the principles of Jurisprudence, the other on the elements of the natural sciences in connection with Medicine; and in awarding two of these scholarships considerable importance will be attached to any special proficiency in the legal or in the Medical subject. Foundation scholars will, by the same examination, be elected from among the undergraduates of the College. Persons who have not been entered at any College in the University, or who have not resided one entire term in any such College, are eligible to these minor scholarships, which will be of the value of 40*l.* per annum, and tenable for two years, or until their holders are elected to foundation scholarships. No one elected minor scholar will receive any emoluments until he has commenced residence as a student of the College. Satisfactory testimonials as to their moral character must be sent to the master by all candidates for these minor scholarships, on or before Wednesday, May 25.

Army Medical Department.—Owing to the scarcity of medical officers in the Indian army, the Army Medical Department is about to hold another competitive examination for assistant-surgeoncies in the royal army on the 21st of March. The age within which candidates may be admitted is extended to thirty years. We feel bound to add that the Indian medical department has stronger grounds of dissatisfaction than the home service; and that the want of officers is only the necessary consequence of the extreme discontent and sense of injury under which the medical officers smart. The Indian papers are full of their unredressed grievances. It will be remembered that the promised Indian Medical Warrant was at the last moment withdrawn; and that the Indian medical officers, between the long debated scheme of amalgamation and a separate Warrant, have been made the playthings of men in office.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. V.

GALLIC ACID.—This acid is found in small quantities in various parts of a great number of plants. It is present in the flowers of arnica, in the seeds of sabadilla, in the leaves of tea and uva ursi, and in the roots of ipecacuanha and rhubarb. But it is found most abundantly, together with another acid, tannic or gallo-tannin, in nut-galls. The amount of gallic acid which exists ready formed in the gall-nut in proportion to the gallo-tannin is, however, but small, and the object of the process given in the British Pharmacopœia is the formation of gallic acid from the former substance.

Gallo-tannic acid belongs to a class of conjugated bodies termed *glucosides*; these bodies are easily broken up under the influence of dilute acids or natural ferments assimilating water, and yielding glucose as one of the products of the change. The Pharmacopœia adopts the fermentation process. Galls in coarse powder are directed to be made into a thick paste with water, and this paste, kept moist by occasional additions of water, is left exposed to the air at a temperature from 60° to 70° F., for a period of six weeks. The changes which take place during this time are somewhat complicated. In general, it is said that oxygen is absorbed from the air, carbonic acid is given off, and gallic acid formed. The actual changes, however, are not quite so simple. Some ellagic acid is always produced, together with alcohol, and most probably other bodies. The ferment which sets up these changes is a nitrogenized body contained in the galls termed *pectase*.

At the end of six weeks, when the fermentation is supposed to be completed, the paste is boiled with water for twenty minutes, and strained through calico while hot. On cooling, the liquor deposits the gallic acid in minute crystals, and any undecomposed tannin is left in the mother liquid. These crystals are to be pressed, and then purified by re-dissolving them in a small quantity of boiling water, from which the acid now deposits in the form of the minute acicular crystals, usually of a pale fawn colour, well known to all who employ the acid.

The above is the process most generally followed in procuring gallic acid, but some modifications have been proposed. It has been recommended to make use of some beer yeast to promote the fermentation, but this ferment is said by Robiquet to have the opposite effect of retarding the process.

A fermentation process, more or less resembling that of the Pharmacopœia, is, we believe, always employed in producing gallic acid commercially; but, as we have said, it can also be obtained by breaking up the gallo-tannic acid by means of a dilute mineral acid. For this purpose the powdered galls have only to be boiled for a short time with dilute sulphuric or hydrochloric acid, whereby the gallo-tannin is resolved into gallic acid and glucose.

$$C_{54}H_{22}O_{34} + 8HO = 3C_{14}H_6O_{10} + C_{12}H_{12}O_{12}$$

Gallo-tannin. Gallic Acid. Glucose.

According to Dr. Stenhouse, when a properly diluted acid is employed, nearly the whole of the tannic acid may be obtained in the form of gallic acid. The crystals are deposited from the strained liquor on cooling as in the former process, and may be purified by re-dissolving them in boiling water as before.

Gallic acid is soluble in 100 parts of cold water, and in three parts of boiling water, and freely soluble in alcohol and ether. Its solution gives no precipitate with a solution of gelatine, which would detect the presence of any tannic acid, from which gallic acid is also distinguished by occasioning no precipitate with the vegetable alkaloids. It is tribasic, and crystallises with two atoms of water; the formula given in the Pharmacopœia is $3HO, C_{14}H_5O_7 + 2HO$. Not one of its salts is employed in Medicine. If carefully heated to 210° or 215° Cent. it gives a sublimate of pyro-gallic acid, meta-gallic acid being left as a residue. When burned with free access of air, gallic acid leaves no residue.

Pyro-gallic acid is largely used in photography as a reducing agent, and in gas analysis to absorb oxygen; it has not yet, however, been employed in Medicine.

ACIDUM HYDROCHLORICUM is a solution of hydrochloric acid gas in water. The solution directed by the British Pharmacopœia is to have the specific gravity 1·7, and will, therefore, contain about 34 per cent. of the gaseous acid. It is a little stronger than the acid of the London Pharmacopœia, which had the density 1·6.

The process given in the British Pharmacopœia would be unexceptionable, but for an unfortunate omission, which has provoked a good deal of criticism. The directions are as follows:—"Take of chloride of sodium, dried, three pounds; sulphuric acid, forty-four fluid ounces; water, thirty-six fluid ounces; distilled water, fifty fluid ounces. Dilute the sulphuric acid with thirty-two ounces of the water, and when the mixture has cooled, pour it upon the chloride of sodium, previously introduced into a flask, having the capacity of at least one gallon. Connect the flask by corks, and a bent glass-tube with a three-necked bottle, furnished with a safety-tube, and containing the remaining four ounces of the water; and from this, conduct the gas into a second bottle, containing the distilled water, by means of a bent tube, dipping about half an inch below its surface; and let the process be continued until the product measures sixty-eight fluid ounces." In the foregoing directions it has been forgotten to state that heat must be applied to the mixture of chloride of sodium and diluted sulphuric acid, without which, little or no hydrochloric acid gas will be evolved. Towards the end of the process,

indeed, it will be necessary to raise the heat almost to the boiling point.

The above proportion represent two equivalents of sulphuric acid, and one equivalent of chloride of sodium, so the changes which take place in the process will be represented by the following equation :—

$$Na\,Cl + 2\,SO_3 + 2\,HO = H\,Cl + Na\,O, H\,O, 2\,SO_3.$$

The commercial acid is usually made by heating one equivalent of chloride of sodium and one equivalent of sulphuric acid ; but with these proportions a much higher temperature is required, and the operation is conducted in cast-iron cylinders. Several impurities are ordinarily found in the commercial acid, some of which may also be present in that prepared according to the Pharmacopœia process. To these we shall presently allude.

Hydrochloric acid gas is a compound of one equivalent of hydrogen (1), and one equivalent of chlorine (35·5). By cold and pressure it may be condensed into a colourless fluid. On escaping into the air it fumes on account of absorbing water. Water dissolves nearly an equal weight or about 500 times its volume of the gas, and this saturated solution has the density 1·20. When pure, the solutions of the gas are perfectly colourless.

By operating with pure chloride of sodium, and pure sulphuric acid, a perfectly pure hydrochloric acid will be procured by the Pharmacopœia process ; but as such an acid will probably remain an extremely scarce article, we proceed to point out the impurities commonly found in the commercial acid. The most important is arsenic ; this may be derived both from the chloride of sodium and the sulphuric acid employed, but most probably from the latter. The object of the three-necked bottle with a small quantity of water, directed by the Pharmacopœia, is to detain any chloride of arsenic which may pass over ; and in order that this may be perfectly accomplished, the tube conveying the gas should be made to dip under the water, and the bottle itself should be well cooled.

Arsenic, if present, would be detected on boiling the acid, diluted with an equal volume of water, with a strip of bright copper foil — Reinsch's well-known test. The chloride of arsenic is thereby decomposed, and a steel grey coating, which consists of an alloy of arsenicum and copper, is deposited on the surface of the metal. When a piece of foil so coated is heated in a test tube, the arsenicum is volatilized, and combining with oxygen from the air, is deposited on the sides of the tube in the form of sparkling octohedral crystals of arsenious acid.

When diluted with four times its volume of distilled water, hydrochloric acid gives no precipitate with chloride of barium, proving the absence of any sulphuric acid. When similarly diluted, it gives no precipitate with sulphuretted hydrogen. This further proves the absence of arsenic which would give an orange precipitate of tersulphide of arsenic, and also of nitric and sulphurous acids, both of which would occasion the separation of sulphur.

Commercial hydrochloric acid and pure acid which has been long kept exposed to the light, is coloured yellow by chlorine, which will bleach a solution of indigo. A similar colour is frequently due to organic matter, and sometimes to peroxide of iron ; the latter will be precipitated when the acid is supersaturated with ammonia.

Hydrochloric acid does not combine with metals, or with metallic oxides. When it attacks metals, the hydrogen of the acid is set free ; and when acting on a metallic oxide, the oxygen of the metal combines with the hydrogen of the acid to form water, a simple compound of chlorine and metal resulting in each instance.

ARMY REPORTS.

No. 1.

STATISTICAL, SANITARY, AND MEDICAL REPORTS FOR THE YEAR 1861.

ISSUED BY THE ARMY MEDICAL DEPARTMENT, OCTOBER, 1863. Pp. 552.

Report on the Gun-shot and Sabre Wounds of Invalids sent to Fort Pitt during the Years 1860 *and* 1861. By Thomas Longmore, Esq., Deputy-Inspector General, and Professor of Military Surgery to the Army Medical School. Pp. 30.

A wholesome dread of blue-books has deterred us for some weeks from opening the ponderous blue volume, with its varied type, tables, and contents ; and we confess that even now we would have deferred it till a more convenient season, had not the pamphlet of Mr. Longmore passed into our hands. This pamphlet we have read with such interest as to induce us to cast our eye over the larger work, and, with little trouble, we have seen the vast amount of information collected in these Reports, and the valuable deductions which yearly may be drawn from their contents, not only for the good of Medical science, but also for the increase of our statistical information, which in future wars will render the Director-General an indispensable and important aid to the authorities at the War Office. As our busy readers may have no time to turn over the bulky volume, we shall briefly give an idea of its contents.

It is certain that Dr. Andrew Smith felt, at the outbreak of the Crimean war, that he had not a single document in his office to help him to statistical conclusions. If these reports be carefully and faithfully worked during war, as they now are in time of peace, there is no reason why they should not show the total deaths from disease, the total deaths from wounds, and the per centage of each to the total strength of the army, and also a most important item hitherto not noticed, namely, the probable period that the Army will be deprived of the services of men in hospital from diseases and non-fatal wounds, and consequently the reports will indicate the number of men which will be required at the expiration of a certain fixed period to fill up the gaps of an army in the field. So that, given the strength of an army, and the probable duration of a certain war, an approximate calculation may be made by the Minister at War of the number of recruits required to sustain the army constantly at its necessary numerical strength. From inattention, on the part of military rulers, to these inevitable inquiries, wars have ended when they should have gone on, and governments saved when they should have yielded or have been destroyed, by the total wasting away of armies. Of the former we have a notable instance in the French Army during the late Crimean war ; of the latter many instances both in ancient and modern wars.

The value of these reports would be much increased if tables of the treatment adopted in cases both of wounds and diseases were appended, especially zymotic diseases, for they are the real enfeeblers and destroyers of armies,

not shot, shell, and the bayonet. We learn, from a table in Dr. Fraser's 'Treatise,' that in the Crimean War 16,298 men perished by disease, chiefly of the zymotic class, and only 1,918 from wounds. The same disproportion was observed in the French army, in which 57,741 perished from disease and only 3,981 from wounds.

In illustration of the subjects dealt on in the statistical report of 1861 of 'Troops serving in the United Kingdom,' we give "enthetic" diseases at page 11.

"The admissions on account of venereal diseases continue very high, exceeding in number one-third of the strength. There has been a slight increase in the proportion in the seaport towns, camps, and at London and Windsor; and a decrease in all the other groups of stations, but particularly at Dublin, the dockyards, and arsenals, and the remaining stations." The admissions into hospital from this class of disease have amounted to 354 per 1,000 of the strength. The number constantly in hospital has been with them 23·45 per 1,000, and the average duration of the cases 24·19 days, in other words 31,476 men out of a grand total of 88,955 men have been admitted into hospital for a disease capable of mitigation by police interference. The inefficiency thereby caused has, therefore, been equal to the loss of the services of every soldier at home for 8·56 days, being a trifle under the amount in the preceding year. 1·85 per 1,000 of the strength is lost annually to the country by invaliding from this cause alone. To show the permanency of this evil, we shall take a few figures from the report of 1859. The annual ratio of men admitted to hospital for syphilis and gonorrhœa was in the infantry regiments 399·4 per 1,000; Dragoon Guards 402; Royal Artillery 571; Military Train 580. Thus, the average would be 422 in every 1,000 men serving on home stations. Referring to Mr. Acton's papers, we find in the garrison at Brussels, only 11 men out of 3,500; while at Windsor 64 out of 600 Fusilier Guards were in hospital for this disease. This* subject must sooner or later be met boldly, and if decided steps can be taken, no maudlin sentiments should be allowed to stop the necessary means to improve and continue the health and efficiency of the British army. We cannot carry out all the means for prevention and cure adopted in foreign countries, and truly there is not much inducement to make similar attempts, seeing the utter failure of the strict segregation system adopted at Hamburg, where nevertheless syphilis is found in plenty; but let us at least do all we can by offering a ready means of entering hospitals to all infected women, and promulgate as much as we can a knowledge of the baneful effects of this disease. If a registry of prostitutes were kept, a concealment of labouring under the disease might be made a misdemeanour; but what are we to make of all the hidden and unregistered cases of disease in our Babylon?

Connected with this subject are two most interesting papers by Drs. Milroy and Aitken, p. 423 and 432, and although we are disinclined to accept, as proved, the connection between syphilis and pulmonary disease, which these gentlemen would infer, yet we take their papers as valuable, from drawing attention to this most important subject. For instance at page 435, Dr. Aitken says,—"For reasons already stated, phthisis must be regarded in many cases as the product of syphilis, and I would fully endorse the statement of Dr. Balfour, from what I have seen in the post-mortem rooms, seems," he says, "that a great cause of pulmonary disease among the guards is the amount of syphilis."

We are ready to admit that the depressing effects of the syphilitic taint will, like any other depressing disease, favour the deposit of tubercle, and very often the circumstances under which syphilis is contracted—viz., habits of intemperance, undue exposure to cold and inclement weather, &c., are of themselves sufficient to light up the tubercular diathesis, without concluding that the one disease supplements the other; or that there is any more connection between the two diseases than that the local irritation caused by syphilitic infiltration will hurry on the deposit of tubercle. If this connection be conceded, how are we to explain the innumerable cases of phthisis occurring in persons of all ages and ranks who have never had syphilis, or where no hereditary taint even can be traced or suspected? In those melancholy cases of children born loaded with a syphilitic taint, the presence of tubercle is only incidental and not the rule.

The observations by M. Grassi quoted at p. 428, "that in the advanced stages of syphilis the blood globule is converted into albumen," proves nothing in point, because albumen constitutes a very small proportion of the component parts of tubercle, and he leaves unexplained the source of the various other component parts of tubercle; besides, if this were the true explanation we should detect tubercle in the blood, which, as yet, has only been suspected but not proved, in a very few cases, although one case is given by Alison in which "tubercle was seen in the decolorised lymph in the right ventricle of the heart, adhering to the lining membrane."

Dr. Parkes does not appear to share in the opinions of his colleagues, for at page 310 he says "The enquiries which have appeared to trace the large amount of phthisis prevailing in the army to the inhalation of a vitiated atmosphere, may perhaps eventually be carried a step farther, and may show that the pulmonary effect is not owing to gaseous impurity, but to the mechanical effect of the manifold particles of different kinds which float about in the air of ill-ventilated rooms."

Mr. Hutchinson, an authority of no small importance in this special field distinctly states in aphorism 57, page 218, in his syphilitic diseases, "There is no reason to suppose that heredito-syphilis in the least predisposes to phthisis, or to the tubercular forms of scrofula." He might have added also "acquired syphilis."

(To be continued.)

Life; Its Nature, Varieties, and Phenomena. By Leo H. Grindon, Lecturer on Botany at the Royal School of Medicine, Manchester. Third Edition, pp. 401. London: F. Pitman.

The fact that this book has reached its third edition sufficiently proves that it has been acceptable to the public. It is by no means a Medical or physiological treatise, but embraces a great number of subjects both in the domains of science and those of literature, which render it instructive and amusing to all classes of the community. From this circumstance, we are precluded from entering at large into a consideration of the manifold subjects of which it treats, and of the arguments which the author employs in supporting his views. A book in which the theories of life in animals and plants are discussed in connexion with the past and future eternity, and in which the nature of the human mind and soul is elaborately examined, is evidently one which cannot be despatched without a lengthened analysis such as our limits do not allow us to make. We must therefore, confine ourselves to observing that the pages of Mr. Grindon's treatise exhibit throughout abundant traces of various learning, and a mind keenly alive to all that is beautiful in nature; while the whole tone of the work is a deeply religious one, harmonising the works of the creation with the doctrines of revelation. The principles advocated are not those of an ascetic, but of one who advises mankind to enjoy with moderation the bountiful gifts which are presented for their use, and the perusal of the book is calculated to inspire humble sentiments of gratitude for the blessings we at present enjoy, and well-founded aspirations for the future destiny of the human race.

---

* Since the above was written, the authorities have taken an initiative step; an order has been issued from the War Department, strictly forbidding soldiers entering certain streets chiefly inhabited by prostitutes in Woolwich, and sentries are to be placed at each end of such streets night and day to enforce obedience. A letter also has been issued by Lord Hartington to the local civil authorities, offering that at least ten affected females may be sent to and kept in the Lock Hospital at the expense of the Admiralty.

GENERAL CORRESPONDENCE.

THE BRITISH PHARMACOPŒIA.

To the Editor of the Medical Circular.

When in the happy days of my "teens," I was serving my master after the manner of a faithful obedient apprentice, I was more than once in "hot water," from the following circumstance. My excellent preceptor held the appointment of apothecary to one of our largest metropolitan hospitals, and although we had a well arranged "Pharmacopœia Nosocomü," yet, to my sorrow, the staff would not adhere to its formulæ. One of these extrinsic favourites was "Pilula Colocynthidis cum Hyosciamo," the manufacture of which devolved on me, and to shorten labour I was wont to make up a goodly mass of the above compound, and roll out any quantity into pills, as they were required. But we had a body of men selected by the Executive from the Medical practitioners on the committee, known as (at least so-called) "The Annoyance Jury," or "Visiting Justices," not of peace, for they always brought war, but really "Visiting Apothecaries." Their duty consisted in prying into every department of the drug and dispensary establishment, and often did they lay hold of my Col. cum hyos. mass and exhibit it to my master as useless. In truth, it was always getting mouldy, and appeared not only to spoil itself, but the activity of the Colocynth extract also, if kept in bulk; yet such is the love of a formula from the Scotch capital, that this most objectionable mass is now ordered to be kept by the British Pharmacopœia; and the man who buys the same, will soon learn, by practical and pecuniary experience, the folly of such a step, if he heeds not this

I am, &c., VOICE FROM THE DRUG ROOM.

THE DIET HOSPITAL FOR THE POOR.

To the Editor of the Medical Circular.

The Diet Hospital! what can that be? we have heard of a hospital somewhere on the continent where none but dietetic remedies are allowed for any disease, but surely no one has had the temerity to try such an experiment in drug-taking England. Yes: a glance at the latest Report tells us that this Institution is intended to "*supplement* the benevolent labours of those, who, while they *give* Medical attendance and medicine, can but *recommend* suitable nourishment, which is often the most important means of cure and the most difficult to obtain.'

Can it be, then, that this Hospital is intended to supply that great desideratum for which the dispensary doctor often sighs in vain? Yes: that is its object.

"Here day by day a meal is spread,
The sick are gathered round;
By Christian kindness hither led
To feast on Mercy's ground."

And a good meal it is, too; consisting of roast meat, bread, vegetables, and porter, direct from the brewer's. The room formerly a shop and parlour) in which this useful and interesting work is carried on is only 21 feet long by about 15 broad, and is situated in a street where most of the houses are let out in tenements to the poor. The large front-window is shaded by a white blind, on which is printed in large letters "Invalids' Dinner-Table or Diet Hospital." A small tablet on the outside gives the further information, that it is an institution for feeding the Sick Poor; that the dinner houris 12.30, and the price of dinner-tickets, 6d. each. Benevolent persons buy these tickets, and give them to poor persons recovering from illness, or suffering from chronic disease. The recipients have to pay ½d. each if they sit at table, 2d. if they have their dinners home. This difference in favour of *table guests* is made partly because their presence insures that the dinners are really eaten by themselves, instead of being shared by other members of their families, and partly because it gives them an opportunity of hearing what may do them good. The additional charge is so far successful that the larger number of invalids dine at the room. Though the allowance is a liberal one, the plates are generally cleared; and then the good old man, whose duty it is to assist the cook in cutting up and weighing out the food, reads a few verses of scripture, and offers prayer; but, as he is under orders to dismiss the people at half-past one, this does not occupy long.

The diners include men, women, and children, some of the latter being very young. Those who have watched the effects of judicious diet, in even the worst forms of infantile disease, will not be surprised to hear that some of the most successful cases have been those of children. It is pleasing, too, to observe the kind feeling which their presence at table often elicits from older invalids, and to hear the hearty laugh which their amusing ways will sometimes send all round the table.

Towards the close of the winter and early in the spring the number of patients often exceeds 100 in the week, though the room is so small that if more than five and twenty dine there at one time, they can hardly be said to be *accommodated.*

The clean appearance of those present makes us think it must surely be a good thing for the poor spiritless invalid, who sits day after day over his smoky fire, putting off to the last moment the fatiguing and chilly operation of washing, to have a motive for making himself decent, and getting a little change of scene, to say nothing of the more substantial benefit of a good wholesome dinner.

In conclusion, we advise all your readers to look in at 66 Earl street, Lisson grove, some morning at half-past twelve, and see for themselves the Diet Hospital at work, which in point of fact is not an hospital at all, but as its less pretentious name informs us, a "*dinner-table*," around which such of the neighbouring sick poor as can obtain tickets gladly assemble every day.

If a little further advice can be tolerated, we would say leave a handsome donation with the Matron, or send one to the Lady Superintendent, and you will deserve the thanks, not only of the afflicted poor, but of all your professional brethren who labour amongst them.

I am, &c., AMICITIA.

[We willingly insert this communication from a lady correspondent, and at the same time express our best wishes for the success of the institution, which, as we know from personal experience, is already effecting a great amount of good, especially among the out-patients of hospitals and dispensaries, who are often as much, or more in need of diet than of medicines.—[ED. MEDICAL CIRCULAR.]

SWEATING IN DROPSY.

To the Editor of the Medical Circular.

SIR,—I have often thought it singular that with the numerous hot-air, or Turkish baths, now scattered through this country, and more or less patronised by the public and our profession, the effects of *copious sudation*, prescribed with judgment, should not be tried in our hospitals or elsewhere, in cases of anasarca or general dropsy, which purgatives, diuretics, &e., too often fail in efficiently relieving.

Not very long since, I had under my care a lady of about sixty-two years of age, whose legs, higher than the knees, had been affected for months past with great œdema (said to be dropsy), and accompanied by a very irritable eruption, of impetiginous nature, for which numerous remedies had been tried in one of the midland counties without much benefit.

She now took at my request, "a simple hot-air bath," long enough to induce free perspiration, from which she derived such immediate benefit and comfort, that it was repeated after two days, so as to occasion more copious and longer sudation.

Suffice it to say, that after a third bath, not only was the eruption dissipated, but her legs and ankles completely restored to the natural size, and her general health, spirits, and comfort, surprisingly improved.

I could discover in her case no symptoms of diseased heart or kidneys, but her habit of life had long been sedentary and inactive.

Are there not many cases of intractable anasarca, &c., in which this simple means of getting rid of the superfluous fluid might be safely tried with advantage, relieving the poor patient of miserable suffering, and perhaps occasionally effecting a cure? I am, &c.,

FRAS. PEPPERCORNE, M.R.C.S.E.

THE MEDICAL CIRCULAR.

WEDNESDAY, MARCH 9, 1864.

MEDICAL EDUCATION.

The subject of Medical Education must be one of the deepest interest to us all, whether as individuals or as a community. The status of each one of us in the Profession has been obtained in a great measure by the education we received while still in a state of pupilage, and the future interests of our successors will materially depend upon the use they make of their time during their career as students. The choice of a good school, the instruction and example of a good teacher, the judicious employment of time, the perusal of useful books, the influence of good associations, all these circumstances may lay the foundation for an honourable, useful, and prosperous career; while, on the other hand, an injudicious choice in any of the above particulars, and even a single false step, may ruin the brightest prospects, may arrest our career on the very threshold of Professional life, or may drive us from the Profession altogether.

While thus asserting that the future of each of us is in a great measure dependent upon the mode in which our early professional training has been conducted, it is needless to remark that it is still more dependent upon our own individual exertions. The old adage "one man may lead a horse to a well, but a hundred cannot make him drink," is perfectly applicable to Medical study, for a youth may be surrounded with every advantage in the way of well-arranged hospital wards, diligent teachers, eloquent lecturers, and abundant books, and yet he may be unable or unwilling to avail himself of their use; and on the other hand, another youth may, by dint of courage and perseverance, overcome every obstacle which may be presented to him by poverty and privation, and by the absence of the advantages just enumerated, and yet become an ornament to his Profession and to the human race. But schemes of education are intended for the many and not for the few, and it is no disparagement to the best system, to assert that it has been found useless or inapplicable in individual cases, or that certain isolated instances have occurred where persons have made their way in the world without any education at all.

In reference more especially to the Medical Profession, there can be no doubt that the amount of literary and scientific information necessary for its successful pursuit has enormously increased of late years; nay, more, we do not hesitate to assert that a great portion of the current and recent Medical literature is either useless or unavailable to the student, and he requires to have some guide at hand to tell him not only what to seek, but what to avoid. Not only is this the case with much of the floating irrelevant science or pseudo-science of the present day, but many facts and theories accepted in former times have become obsolete by the advance of knowledge, and therefore worthless except to those who study the history of Medicine in an antiquarian spirit.

To tell a youth, therefore, who designs to enter the Medical Profession, that he must rely on himself and distrust those who occupy the position of acknowledged teachers, may be good advice enough in a certain sense—namely, to encourage in him habits of self-reliance and a salutary scepticism as to Medical dogmas; but if it is meant that he is to pursue his studies as his own fancy may dictate, choose the parts of the established curriculum which he prefers, and neglect all the rest, attend what lectures he pleases, and absent himself from others, and amidst a host of books, some of them of enormous dimensions, pick out for himself those he thinks most inviting:—then all we can say is, that he who follows such advice will, in nine hundred and ninety-nine cases out of a thousand, either become an incompetent practitioner in the long run, or rapidly give up the Profession in disgust as a hopeless pursuit.

For many years it has been the fashion to decry what is called the system of apprenticeship; and, undoubtedly, if the relationship between master and apprentice is merely a trading compact, money being exacted on one side and mechanical services rendered on the other, the sooner it is abolished the better. But if the master is a conscientious man, willing and able to impart information, even upon minor points connected with medicine and surgery, and the pupil is docile and industrious, and if, moreover, this preliminary pupilage lasts only for one or two years, then we cannot, on any reasonable ground, see what objection exists to the system. Nay, more, we consider that such a relationship between master and pupil is positively advantageous, and that the present neglect of the opportunities afforded by provincial hospitals, infirmaries, and workhouses, to young Medical pupils, is already producing most disastrous consequences to the rising generation of students.

If, indeed, it be urged that boys should be kept somewhat longer at school for the purpose of pursuing abstract or scientific studies, then it is necessary that their period of Medical study should be prolonged in proportion, and no objection can be urged against such a system, except the following, which, although altogether a pecuniary one, is of very great importance. It must be recollected that the great mass of Medical students must be qualified for practice at twenty-one years of age, at which time they are able to earn their living. Hence, if a boy is to be kept at school learning classics and mathematics until he is eighteen, it is evident that he will require to pursue his Medical studies after he is one and twenty, unless indeed the ingenuity of the present age should discover some royal road to Medical knowledge, which may obviate the usual laborious steps by which that knowledge is attained.

Here, however, we must protest against the notion entertained by some well-meaning people, that the education must be alike for all. It is quite true that the fundamental principles of medicine and surgery are the same, and that a knowledge of anatomy is as essential to a Medical practitioner as an acquaintance with the alphabet. But shall it

be said that a knowledge of anatomy *alone*, even if it be a thorough knowledge, is sufficient for a Medical practitioner of the present day? and yet we fear that not a few candidates rest their claims to admission into practice merely upon a superficial knowledge of this one subject; and what is more, they sometimes succeed in their attempt. But something in addition is certainly required, even to secure a minimum of qualification, and the object of the authorities has been lately to determine how far the minimum should descend. Botany, in very many cases, has been swept away, Physiology has been reduced to two lectures a week, Materia Medica has been contracted into a three months' course, Midwifery has met the same fate, Chemistry is generally neglected, and now the question is, how much is left?

The fact is, as all who are in the least degree acquainted with human nature will admit, that the majority of students will content themselves with the minimum of study, and one of the chief objects of a student's inquiry is, what the minimum is that will enable him to pass. It is equally true that most students, having attained the object of qualifying themselves for the Profession, will pay but little subsequent attention to scientific pursuits, and many have no time to do so, even if they were so inclined.

Such, however, is not the case with all. There are many ambitious spirits who are not satisfied with merely fulfilling their prescribed duties, but who have lofty aims and devote themselves to more severe study. We contend that this latter class deserve higher honours than the former, and that the attempt to amalgamate them all together, is both unfair and unwise; unfair, because he who has worked the hardest ought to reap the greatest reward; and unwise, because it discourages the pursuit of science, which it ought to be the aim of those in authority to promote to the utmost of their power.

SUMMARY OF THE WEEK.

MEDICAL ETHICS AT GREENWICH.

We entirely agree with the 'Lancet,' that the best mode of settling differences among Medical men is by a Court-Medical, instead of by the cumbrous and costly machinery of the law; but at the same time it is only fair to expect that such a Court-Medical should be properly constituted, and that both parties in a dispute should consent to abide by the decision. From information which has reached us, we hardly think that all the rules of fair dealing have been observed in a case which lately occurred at Greenwich, involving some matters of difference between Dr. Purvis and Dr. Moon. It appears that Dr. Purvis, having some cause of complaint against Dr. Moon, called a meeting by a circular marked "strictly private," at which Dr. Moon was requested to attend, but did not do so, owing, it is stated, to his doubt as to the competency of the tribunal, and to his imperfect knowledge of the charges on which he was to be arraigned. It seems that at this "strictly private" meeting a reporter was present, and after the charges made by Dr. Purvis against Dr. Moon, which were three in number, had been heard and discussed, Dr. Purvis withdrew two of them, and the third, which was to the effect that Dr. Moon had written an incorrect certificate, was explained and apologised for by the friends sent to represent the latter gentleman. The result was that Dr. Moon was exculpated from the charge of unprofessional conduct towards Dr. Purvis, and the meeting was satisfied with the explanation. Here the matter might surely have dropped, and Dr. Purvis and Dr. Moon might have shaken hands and forgotten the transaction; but it appears that the 'Lancet' not only published the particulars of this "strictly private" meeting, but actually misrepresented the result, announcing it as condemnatory of Dr. Moon, whereas it was just the reverse. Not only was this done, but we are informed that a garbled report of the meeting, professing to be extracted from the columns of the 'Lancet,' was printed and distributed through the town of Greenwich. This is the version of the affair that we have received, and the 'South London Journal,' in a very temperate and well-written leading article, throws grave doubts on the competency of a Court-Medical to deal with questions affecting professional men, as long as the court is composed in the manner we have described, and its transactions are conducted with such unbecoming irregularity. Dr. Finch, of Blackheath, has written a letter in the same journal, giving what he conceives to be the true version of the whole transaction, and stating that the results of the meeting were exculpatory of Dr. Moon. As we ourselves know but little of any of the parties concerned, but believe them all to be respectable men, we merely make the above remarks in a spirit of justice and fair dealing, hoping that they may help to effect a reconciliation between the belligerents in the late unpleasant misunderstanding.

THE DIET OF PRISONERS.

We have alluded on a previous occasion in terms of remonstrance, to the absurdity of over-feeding prisoners, and thus rendering their condition more desirable than that of the honest and hard-working labourer, and we commented upon a representation made some time since by the Middlesex magistrates to Sir George Grey on this subject. The opinion appears lately to have been gaining ground, that crime is rather encouraged than repressed by the present mode of treating criminals, the excellent diet they receive being a material element among their other comforts. The topic has again been prominently adverted to in a discussion which took place on Friday evening last, in the House of Commons, on the occasion of the second reading of the Penal Servitude Acts' Amendment Bill, many of the members protesting against the excessive dietary allowed to prisoners. Sir George Grey, we are glad to perceive, has directed his attention to the subject, and he stated that a committee had been appointed, comprising three medical men, to inquire and report upon the diet of prisoners, with a view to the alteration of the present system. The object in future would be to allow prisoners only so much food as to preserve them in health. We hope that this view

of the Home Secretary will be fully carried out in practice, and that no morbid sympathy with criminals will induce a perseverance in a course which renders the position of a convict preferable to that of a poor, but honest man.

THE COUP DE GRACE TO SARRACENIA PURPUREA.

We have never failed to denounce the absurdity of vaunting the wonderful powers of a supposed remedy, long before it has been put to the test of experience, and we have still more emphatically condemned the practice of publishing wonderful cures in the columns of the lay journals, inasmuch as such announcements are calculated to raise false hopes and to disseminate error, even if they are not inserted for a mere trading purpose. The last number which has reached us of the 'American Medical Times,' contains a short paper, showing the worthlessness of Sarracenia in Small-pox, and the Editor thus sums up his opinion of the merits of that drug:—

"SARRACENIA PURPUREA IN SMALL-POX.—The Sarracenia has finally been submitted to a trial, which would seem to prove conclusively that it has no specific virtues in small-pox. The cases related by Dr. Levings in another column, where the article was obtained from Major Lane himself, are too accurate to allow a doubt of the fairness of the trial. It is time the Profession put an end to the pretensions of those persons who are endeavouring to palm upon the community a remedy of no value."

THE MEDICAL PROFESSION AND THE PRIZE RING.

For the benefit of any of our readers who may be patrons of the noble art of boxing, we extract the following from the advertising columns of the 'Lancet;' but before we found that it appeared in the pages of our contemporary, we were not aware that the proceedings of prize-fighters had any interest for the members of our Profession. However, we live and learn, and here is the advertisement. For our own part, we did not know that our printing-office was in such close contiguity to the "Academy" referred to, and we are, of course, grateful for the information:—

"SPARRING.—Young Drew (of the P.R.) has opened an Academy for the 'Noble Art,' at Mr. Ashley's, 'White Hart,' Little Windmill street, Haymarket. Hours of attendance from ten till four in the day, and from eight till ten in the evening. Gloves, dumb-bells, &c., found."

The 'Dublin Medical Press' remarks that—"This unworthy touting for the patronage of the P.R. is beneath any respectable journal, let alone that which claims to direct the course of Medical opinion in England."

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

MR. I. BAKER BROWN continues his "Clinical Lectures on some of the Diseases of Women, Remediable by Operation," and his present subject is "Vesico-Vaginal, and Urethro-Vaginal Fistula," the operations for the cure of which are described with the aid of illustrative diagrams. The lesions in question arise, for the most part, from protracted labour, but they arise also occasionally from lithotrity, and from the use of the old wooden pessary. Mr. Brown attributes the present successful treatment of vesico-vaginal fistula to the employment of silver-wire sutures, as recommended by Dr. Marion Sims, of New York, in place of the ordinary twine or silk sutures. The operation is simple enough in theory, consisting solely in paring the edges of the fistulous opening, and bringing them together by the sutures; but in practice, great nicety and considerable time are required. The operation of taking out the sutures is much more difficult than putting them in, and unless every part of the wire is removed, the patient may be exposed to great inconvenience. Inspector A. J. SEMMES, of the Confederate States Army, contributes some "Reports of Cases of Gun-shot Wounds, in the General Military Hospital of Camp Winder, near Richmond, Virginia," and the report is accompanied by some remarks by MR. LONGMORE, of Netley. Mr. W. DUNNETT SPANTON contributes a short paper on the "Use of Collodion as an Application in Cases of Hernia Cerebri." The usual treatment of this affection consists in the application of pads of lint soaked in lime-water, combined with pressure, and if necessary, shaving off the granulations as they spring up. Mr. Alexander Shaw is said to be the first surgeon who employed collodion instead of the ordinary application, and Mr. Spanton employed the same substance in the case he now relates, which was that of a boy whose skull was fractured by the kick of a horse, requiring the depressed bone to be elevated. After a short time, however, the brain protruded, and was treated by the application of collodion with eventual success.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. GARROD continues his "Lectures on the British Pharmacopœia," introducing a variety of subjects, most of which have already been reported or discussed in our pages. Among the more important substances described are scammony resin, podophyllin, the preparations of iodine and of mercury, the alcoholic and ethereal preparations, including the spiritus ætheris, the spiritus chloroformi, and the spiritus ætheris nitrosi. With regard to the latter compound, ordered to be prepared by distilling the nitrite of soda with rectified spirit and sulphuric acid, Dr. Garrod speaks of the new process with commendation, but it is now proved that, however good the plan may be in theory, it is useless in practice, because the nitrite of soda cannot be obtained by the method described. Rectified pyroxylic spirit is the wood or methylic alcohol recommended by some authorities as being useful in phthisis, but its efficacy is very doubtful, and its introduction into the Pharmacopœia is unaccountable. Dr. GEORGE HARLEY continues his "Lectures on the Urine, and Diseases of the Urinary Organs." The amount of urinary solids excreted is sometimes increased, sometimes diminished in disease, the latter being the most usual occurrence, and the same abnormal conditions are induced by medicines; opium, iron, conia, hyoscyamus, and Indian hemp, reducing the quantity, and digitalis, atropine, colchicum, and alcoholic drinks increasing it. Dr. W. O. PRIESTLEY gives a notice of an "Instrument for Dilating the Canal of the Cervix

Uteri," the advantages it possesses being its small size and the facility with which it may be made to assume any required curve. Dr. DAVID H. STIRLING communicates a paper on "Digitalis in Cardiac Disease," and details three cases in which that drug was administered with good effect. The results seem to prove that digitalis has the power of regulating the action of the heart when its functions are disturbed, but none of the cases indicated any structural disease of the organ. Dr. Stirling has employed digitalis in some cases of mitral regurgitation, but without good effects. In cases of weak and irritable heart, digitalis appears to act as a tonic, especially when used in combination with iron.

THE 'DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE.'
NO. LXXIII. FEBRUARY, 1864.

Mr. PORTER commences the number with some "Contributions to Operative Surgery," and relates the particulars of two cases, one being an excision of a portion of the ulna, the other an amputation through the condyles of the femur, and he also calls attention to the importance of excising a small portion of the windpipe in the operation of tracheotomy. He adduces several reasons showing his grounds for preferring this proceeding to opening the trachea by a slit-like incision. Dr. HERMANN WEBER offers some "Notes on the Climate of the Swiss Alps, and on some of their Health Resorts and Spas." Dr. Weber enters into the consideration of a number of physiological problems connected with the influence of high altitudes on the human system, and he examines the physical characters of the Alpine regions in their effects upon health, but he admits that our knowledge on these subjects is at present very imperfect. It is proved, however, that cases of disturbed digestion are very much improved by residence on the Swiss mountains. Dr. R. MCDONNELL makes some "Observations on the Treatment of Certain Forms of Epilepsy," and advocates the use in such cases of the bromide of potassium, which he has prescribed with some success. DR. ALFRED M'CLINTOCK relates a "Case of 'Missed Labour,'" by which term he indicates a peculiar condition presented by some women in whom the period of labour passes over, and the decomposing fœtus remains in the uterus. This is a very rare occurrence, but some well-authenticated cases are recorded, and Dr. M'Clintock's case is a very interesting one of the kind. The patient died after many portions of the fœtus had been artificially removed. Dr. H. R. DE RICCI contributes a paper entitled "Iridectomy and Division of the Ciliary Muscle Compared," and although the cases he records are not exactly from his own practice, he writes in favour of Iridectomy as useful in certain conditions. Mr. G. R. SYMES gives a paper on "Amputation at the Ankle-joint, according to the Method of Professor Syme," and illustrates his remarks by the details of two cases in which this operation was performed. Dr. T. W. BELCHER gives a "Description of a Bed intended to be used in Protracted Fever Cases," and which he thinks would be particularly useful in bed-sores, and in typhoid fever where it is necessary to use the bed-pan with as little disturbance as possible. Mr. MAURICE H. COLLIS contributes an article on the "Treatment of Anthrax by Pressure," illustrated by some successful cases, and Mr. THOMAS POWELL gives a paper on the "Forceps in Craniotomy," the object of the writer being to show that, after the perforation of the head is accomplished, the use of the forceps is preferable to that of other instruments in completing the extraction of the fœtus.

THE 'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

Treatment of Hysteria.

The remedies recommended in the treatment of hysteria are almost invariably derived from the class of antispasmodics. Indeed, authors have too long been struck in the history of this disease, with the most prominent symptoms only, and have not taken the trouble of tracing the nervous disturbances to their true cause, nor of inquiring into the manifold morbid conditions which govern their manifestation. Hence the resources of medicine have been applied but to the relief of the paroxysms, and no serious effort has been made to avert their return.

In order to establish the treatment of hysteria on rational grounds, Mr. Beau opines that the fact should never be loft sight of, that the patient is not only afflicted with a nervous temperament, which is a predisposition to undue reflex action, but must also have suffered previously from obstinate dyspepsia; the causes of the latter condition may vary, but its consequence is anæmia, which aggravates the intensity of the nervous symptoms, and adds to their obstinacy.

The mental causes which induce dyspepsia are the same as those which lead to hysteria. The uterus, on the other hand, is a centre from which impressions radiate, and any disturbance of its function may give rise to dyspepsia, and thus indirectly produce hysteria. We recorded on a previous occasion two instances in point, in which the removal of the uterine disease effectually cured the hysteria.

In addition to mental, cerebral, or uterine causes, Mr. Beau believes in the influence of gastric disturbance, whether it be the result of the presence of worms, indigestion, or of a saburral condition of the primæ viæ. In a patient lying in the professor's wards, we were enabled to detect the simultaneous existence of all these causes. Hysterical fits were induced by the most futile annoyances, and the paroxysms invariably reappeared with the catamenia, or after the ingestion of certain articles of food. Thus, a descending action influences the stomach of hysterical subjects, the brain is affected by an ascennding action, and the womb by direct or gastric influence.

The mere fact of the presence of dyspepsia indicates a watery condition of the blood, and anæmia, of all circumstances the most favourable to the development of nervous symptoms. Hysteria, therefore, is seldom observed in vigorous subjects, *sanguis moderator nervorum*. If a strong woman, by exception, becomes affected with the disease, it is but after having first suffered from dyspepsia and consequent anæmia. When the latter supervenes, gastric dyspnœa makes its appearance, rises to the throat, and induces reflex action, which is promptly followed by nervous paroxysms.

These preliminary remarks clearly point out the most appropriate course of treatment in hysteria. It is obvious that the causes must be removed, and in the first place discovered.

If it is impracticable to remove at once the causes of mental distress, which may have induced the malady, it will be proper to endeavour to divert the patients thought into new channels, by amusement, change of scene, and regular and persevering occupation. Some women are liable to nervous paroxysms only when time lies idly on their hands. We are acquainted with one lady who cured herself by severe bodily exertion, and by direct personal superintendence of the management of her house, which

her position and means rendered it unnecessary for her to attend to. Another patient has been greatly benefitted by gymnastic exercise. He was a thoroughly dyspeptic subject, and regular muscular exertion has improved his digestion, and the tone of his system. A month ago he expressed his regret that he had not sufficient firmness to commit suicide, but is now full of hope, and attached to life. In this instance, hydropathy entirely failed in effecting a cure, and yet it is a method of treatment which may often be prescribed with fair prospects of success.

With regard to the womb, it is always necessary to ascertain its condition, and to relieve any local symptom which may be present, as in the two cases above referred to.

The state of the stomach likewise requires attention. Loss of appetite, a foul tongue, &c., will indicate the propriety of an emetic, and if worms be present, anthelmintics should be resorted to.

The nervous symptoms and paroxysms must not be neglected, and for these valerian baths are, in Mr. Beau's opinion, the most efficient remedies.

The diet is of peculiar importance, and should not be systematically laid down, but be appropriated to the taste and digestive aptitude of each patient. The object is to administer food which may be properly assimilated, and every means of attaining this object is justifiable. No practitioner entertains, in this respect, more conciliating and more liberal views than Mr. Beau.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEB. 23RD, 1864.

MR. PARTRIDGE, PRESIDENT.

As soon as the Honorary Secretary had read the minutes of the preceding meeting of the Society,

Mr. HULKE rose and said that he wished to enter his protest against a proceeding which had taken place at the last meeting. His paper had then been read out of the order which had been announced in the journals and elsewhere, and without any notification of the intention to do so having been made to him. He had no personal feeling in the matter, but as a principle it was bad to read a paper in the absence of the author when it could be avoided. Had he been informed that his paper would be read he might have illustrated it by diagrams; and he thought some law should be in force on the point, and that it was the duty of the secretary to acquaint authors when their papers would be read.

MR. BIRKETT explained that the paper was read to suit the time of the Society. He was not aware that there were any illustrations to it; and his notice to an author was not obligatory, but merely one of courtesy.

The PRESIDENT remarked that the custom of the Society was to read the papers in the order announced; but the secretary could not, of course, determine how long the paper might take to read, or how far the discussion upon it might extend. Under these circumstances, it might occasionally be necessary to substitute a short for a long paper.

After a few more observations the subject dropped.

GEORGE NAYLER, Esq., made some remarks.

ON ALOPECIA.

Alopecia circumscripta, or areata, is a disease little noticed by any author except Cazenave, who confounded it with vitiligo of the scalp. It is far more frequent in the female than in the male, the relative proportion being that of seven to four between the two sexes; and it is chiefly observed about the period of puberty. It is a non-contagious disease, and may be represented by almost any number of circular bald patches on the scalp; very protracted in its progress, and tedious to heal. Alopecia is often associated with headache, especially in the female, or with some disorder of the catamenia; and in children, with ascarides or some gastric irritation. No pain or any previous symptom indicates the disease, which is generally unperceived for some time by the patient. The patch is of ivory smoothness, and ends in a circumference of sound unbroken hair.

When recovery takes place, the new hair is finer and softer than the old, and in some instances perfectly white. (The author had recently seen a patch in a lad of eighteen years where the new hair was quite white.) A microscopical examination shows the hair-bulb to be reduced to a fine point, or the bulb to be slender, and sometimes ending in brush-like filaments. In the stages of recovery, the bulb by degrees assumes its normal shape and size; but the hair itself for a long time retains its fineness and lighter colour.

Alopecia is regarded by most French writers as a parasitic disease, as by Bazen, Harding, and others; but no instance of a parasite has been found by Mr. Startin or the author. Mr. Hutchinson once detected it; but this may have been a case of T. tonsurans or Pit. versicolor of the scalp.

The prognosis is favourable, particularly when the disease is recent and the patient of early age or below puberty.

The treatment consists in attention to the general health, and in giving steel. The local treatment is of much importance. The surface affected should be painted from time to time with some blistering fluid, and in the intervals with some form of mercury or sulphur, either as an ointment or a lotion, or a lotion of the tinctura lyttæ. In protracted cases, mercury and arsenic in *small* doses may be given internally.

In general alopecia the prognosis is less favourable, and when the disease is of long standing no good result can be expected. This form of alopecia differs from alopecia areata only in involving a greater extent of surface.

WM. SCOVELL SAVORY, Esq., read a paper

ON THE ABSORPTION OF DEAD BONE.

Can dead bone be absorbed? This question still awaits a satisfactory answer. For while careful and accurate experiments have furnished only negative results, there are unquestionable facts which compel us to admit the possibility of the occurrence. One all important consideration seems to have been hitherto neglected in the inquiry—the influence of pressure in determining the result. Thus, in the experiments which have been performed on the subject, and which have naturally led to the conclusion that dead bone may be kept amidst living tissues for weeks or months without losing the merest fraction of its weight—in these experiments the dead bone was kept in simple contact only with living parts. It appears that no considerable pressure was maintained. Whereas when ivory pegs are driven into bone, extreme pressure is of course produced. In order to test this view, some experiments were performed which are related in the paper. It appeared to the author that the only explanation which can be offered of the results of these several experiments is, that the absorption of dead bone, when in contact with living bone, is determined by the *pressure* to which it is subjected.

The PRESIDENT said the communication was interesting in connexion with the experiments of Mr. Gulliver. The state of the fragments in cases of ununited fracture had been noticed before; but it had not been attributed to the cause which was explained in Mr. Savory's paper.

MR. HILTON said the profession ought to feel obliged to Mr. Savory for having adduced by well-considered and well-arranged experiments such conclusive evidence of the absorption of dead bone by the surrounding living tissues—a fact not usually admitted by surgeons. He (Mr. Hilton) had several times noticed, on looking at two ivory pegs which had been employed in the same case of ununited fracture, and apparently under the same conditions, that the surface of one of them was partially absorbed, whilst the other did not manifest any loss of substance—a difference hitherto inexplicable, but now elucidated by the author's paper, as depending upon the variable pressure to which they had been subjected. An interesting point, however, presented itself for consideration, to which the author had not made any reference—viz., What was the amount and duration of pressure required to induce this absorption? for dead bone was often seen buried within granulations which were undoubtedly capable of exerting much pressure without the slightest appearance of any absorption having occurred.

For instance, in the case of an amputation through the femur, the same end of the bone may come away necrotic after several months' subjection to the pressure of muscles, fascia, granulations, bandaging, and strapping, yet the track of the teeth of the saw used at the amputation would be seen as cleanly cut and as sharply defined as on the day of the original operation. The same kind of facts was quite as discernible in cases of compound fracture of a long bone, where the fractured end of bone, although surrounded deeply by granulations and new bone during several months, would present the sharp, well-defined edge of the fracture as evidently as on the day of the accident, uninfluenced by the pressure of any of the surrounding living tissues. Mr. Hilton had removed from the leg several portions of a comminuted compound fracture of the tibia eight years after the accident and seven years after the closure of the external wound, and upon two of them the well-defined edge of the original fracture was obvious and markedly different from the serrated edge observable where the piece of bone had been separated from the living bone by the slow process of absorption. Mr. Hilton would suggest to the author the inquiry as to how or by what combination of minute events does pressure contribute towards absorption of the dead bone, because the pressure in his (Mr. Savory's) experiments was made equally on both the living and dead bone. No doubt such an investigation could not be placed in better hands than those of the author of the paper.

Mr. Partridge inquired whether the absorption of the pegs was greater in the shaft of the bone or in the medullary canal?

Mr. Savory said absorption was greater in the shaft portion than in the medullary canal.

Mr. Coote said that Mr. Savory's experiments were very interesting in confirming the view entertained by many surgeons that, in the removal of dead bone, the action of the absorbents was possible in the material that had perished. He had himself witnessed the corrosion of the surface of ivory pegs introduced into living bone for the purpose of promoting union in a non-united fracture. The possibility of the fact, which had been doubted, was important; but, after the experiments thus detailed, could not be denied. He (Mr. Coote) thought that perhaps pressure alone was not sufficient to explain the phenomena of removal. He had witnessed the separation of large portions of bone, which he believed to be dead, on which no pressure could have been exerted. But the fact remained the same; and the value of Mr. Savory's observations must be undisputed. He (Mr. Coote) concluded with some remarks on the relative size of sequestra and the bony cavities which contained them.

Mr. Brooke said that he doubted whether the process by which the surface of the pegs was eroded could truly be designated a process of absorption. He thought it probably analogous to the process of disintegration, by which the surface of a sequestrum is acted on by the highly-vascular granulating surface with which it is in contact. That disintegration, and not absorption, is going on in cases of necrosis, may generally be rendered evident by the appearance of the *débris* of bone-tissues in the pus discharged from the cloaca.

Mr. Wood asked the author whether, in each of the experiments detailed, the condition of the medullary membrane in contact with the peg had been observed, as regarded the presence of granulations of other absorbing structure. In many of the cases in which the pegs had been loosely inserted, extensive suppuration, and in some instances death, had followed. Could the action set up in these cases have been that of a process destructive to the absorbing, or vital powers of the bone and medullary membrane operated on, this would of course prevent the occurrence in these experiments of any absorption of the foreign or dead bone. He presumed that in all the experiments pegs made of the same dried bone had been used, and that there was in no case introduction of putrid matter. In most of the pegs shown in the box handed round which exhibited any evidence of roughening, this extended equally through the parts embedded in the bone of the animal, although only the part traversing the compact tissue of the cylinder of bone had been subject to pressure. The intermediate portion had been in contact with the medullary substance. In the specimen from which the drawing was taken the peg seemed even more attenuated in the cavity of the bone than where in contact with its walls.

Mr. Solly remarked that, while agreeing with all the former speakers in the great value of Mr. Savory's paper, he did not think that it subverted all the old opinions that dead bone could not be absorbed except under pressure: for instance, in necrosis of the parietal bones—a good case of which he had in his mind's eye, where the bone died, became black, lost its sensibility, and was then separated from the living bone because it was dead. The sequestrum which was thus cast off was perforated in all directions, as though worm-eaten, and absorbed in patches. Was not this an instance of dead bone being absorbed without pressure? Had not every surgeon in the room seen such cases?

Mr. Savory, in reply, said he had considered it best in the paper simply to demonstrate the fact that the absorption of dead bone is determined by the pressure to which it is subjected. In working at the matter, of course, he had thought of the nature of the influence thus exercised, but he did not consider any opinion which he might have formed on the subject worth expressing. The question was not in relation to the absorption of bone, whether living or dead, but to the effect of pressure on the absorption of dead bone. With respect to the case Mr. Solly mentioned, it was not enough to show that dead portions of bone bore evidence of having been partially absorbed: it must be shown that such absorption occurred after the death of the bone, and thus independently of all pressure. Mr. Savory defended the use of the word "absorption." He had not employed the term without foreseeing the objection that might be urged against it; and so he had been careful to relate how, in some of the experiments, the wounds at once closed, and completely healed without any discharge or other means by which disintegrated fragments of bone might have escaped. Moreover, if the preparations were examined it would be seen that, in some of them, the portions of dead bone which had been removed could not have escaped, for the holes were tightly plugged by the pegs which had been driven in. With reference to the destination of the bone which disappears in disease, Mr. Savory thought that the evidence advanced to prove that this is always disintegrated and cast out was unsatisfactory and inconclusive. Of course, in some forms of ulceration of bone, as in phagedenic ulcers of soft parts, disintegrating fragments might perish and escape; but in other less destructive forms of ulceration bone might disappear through absorption. Much had been made of the fact that the discharge from carious bone contains an unusual abundance of phosphate of lime, this being supposed to represent the dissolved osseous tissue. But while, on the one hand, this would prove too much, the proportion of bone which disappears not being equal to the quantity of phosphate of lime discharged, on the other hand, a better, a more philosophical explanation of the fact might be given. As in health each part assimilates to itself from the blood its own proper constituents, so in abnormal forms of nutrition, it was reasonable to believe that the material furnished by different structures would present characters of composition more or less corresponding with those of the tissue whence it proceeded. Be this as it might, however, in some at least of the experiments described there was no means by which the portion of bone which had disappeared could have escaped externally.

JUNIOR MEDICAL SOCIETY OF LONDON, Feb. 17.

Mr. J. Warrington Haward read a paper on

THE TREATMENT OF HERNIA.

The author considered first the treatment of strangulated hernia, and showed, by statistics and argument, the evils of forcible or prolonged taxis. He next alluded to the auxiliaries to the taxis; deprecating the use of tobacco, purgatives, and

bleeding; recommending ice to the tumour in some cases, but advocating the inhalation of chloroform as by far the most valuable measure.

He strongly insisted upon an early operation, having proved the mortality to be in exact proportion to the time of strangulation, and the amount of taxis used.

He then entered on the question of opening the sac; and examined the arguments for and against this proceeding, proving by statistics, and an analysis of the cases that had occurred at St. George's and other Hospitals, that the mortality is less, and the advantages much greater, in the operation in which the sac is opened, than in that in which this structure is not incised The treatment recommended after the operation was that of keeping the bowel at rest by opiates. Having spoken of irreducible hernia, the reducible variety was then treated of, and the operations for the radical cure, known respectively as Wützer's and Wood's, were explained. The author entered in detail into the latter, which, in his opinion, is by far the most satisfactory that has yet been devised, and one worthy of a trial in appropriate cases.

An interesting discussion ensued, in which Messrs. Freeman, Gill, Smith, Ransford, Edgelow, Bell, &c., took part.

Births, Marriages, and Deaths.

BIRTHS.

BLAIR.—on the 23rd of Jan., at Dailly, Maybole, Ayrshire, the wife of T. Blair, L.F.P. & S. Glasg., of a son.

BUCHANAN.—On the 24th ult., at Douglas street, Blythswood square, Glasgow, the wife of George Buchanan, M.D., of a daughter.

CHAMBERS.—On the 28th ult., at Sunderland street, Warwick square, the wife of T. Chambers, L.R.C.P.Ed., of a son.

COLEBROOKE.—On the 28th ult., at Southborough, Tunbridge Wells, the wife of H. Colebrooke, M.D., of a son.

CÆSAR.—On the 29th ult., at Downton, Wiltshire, the wife of R. T. Cæsar, M.R.C.S.E., of a son.

DEBENHAM.—On the 29th ult., at Heath House, Commercial road East, the wife of Robert Debenham, M.R.C.S.E., of a son.

FINCH.—On the 29th ult., at Stainton Lodge, Blackheath, the wife of R. Finch, M.D., of a daughter.

FRASER.—On the 18th ult., at the Portobello Barracks, Dublin, the wife of T. Fraser, M.D., Surgeon 10th Hussars, of a daughter.

JENNER.—On the 27th ult., at Harley street, the wife of Dr. Jenner, of a son.

LOTHIAN.—On the 25th ult., at Windsor place, Sauchiehall street, Glasgow, the wife of J. A. Lothian, M.D., of a son.

MACKENZIE.—On the 2nd inst., at Sidmouth, the wife of J. Ingleby Mackenzie, M.B., of a son.

MAJOR.—On the 18th ult., at Hungerford, Berks, the wife of Harry P. Major, M.D., of a daughter.

MURRAY.—On the 22nd of Jan., at Tranquebar, the wife of J. Murray, M.D., of a son.

PALFREY.—On the 3rd inst., at Wellington street, London bridge, the wife of Dr. Palfrey, of a son.

POPE.—On the 25th ult., at Ulverton terrace, Dalkey, Co. Dublin, the wife of J. A. Pope, F.R.C.S.E., of a son.

ROBINSON.—On the 21st ult., at Baltimore, Skibbereen, Co. Cork, the wife of S. W. Robinson, M.R.C.S.E., of a son.

SHAW.—On the 26th ult., at Sutton-Coldfield, the wife of H. E. F. Shaw, M.R.C.S.E., of a daughter.

SMITH.—On the 2nd of Dec., at the Kyneton Hospital, Melbourne, the wife of S. Smith, Resident Surgeon, of a daughter.

WEBB.—On the 27th ult., at St. George's road, Pimlico, the wife of Dr. E. L. Webb, of a son.

WORKMAN.—On the 26th ult., at Reading, the wife of F. Workman, M.R.C.S.E., of a son.

MARRIAGES.

HOYSTED—SMITH.—On the 24th ult., at Christchurch, Bradford, Yorkshire, T. N. Hoysted, L.R.C.S.Irel., Staff-Assist. Surg. Army, to Isabella, daughter of the Rev. W. R. Smith, M.A., Incumbent of Christchurch, Bradford.

JOYNSON—BROMILOW.—On the 24th ult., at Christchurch, Harpurhey, G. T. Joynson, L.F.P. & S. Glasg., of Northwich, Cheshire, to Maraquita Beatrice, daughter of the late J. Bromilow, Esq., of St. Helena.

SIBBALD—PHELAN.—On the 27th ult., at St. Mark's Church, St. John's wood, J. Sibbald, M.D., of Lochgilphead, to Sarah Jane, daughter of B. P. Phelan, Esq., of Clonmel.

WEBB—LEWIS.—On the 22nd ult., at Knockmark, Co. Meath, T. W. Webb, M.D., of Dundrum, Co. Tipperary, and Ross House, Co. Meath, to Hesta Henrietta, daughter of the Rev. J. T. Lewis, M.A., Rector of Knockmark.

DEATHS.

GREEN.—On the 23rd ult., J. Green, M.D., late of Great Marlborough street, aged 76.

HEAZLE.—On the 22nd of Nov., at Burgersdorp, Cape of Good Hope, T. Heazle, L.R.C.S.Edin., late Staff Assistant Surgeon Army.

JOHNSTON.—On the 18th ult., at Belfast, F. G. Johnston, M.R.C.S.E., formerly of St. Angelo, Co. Fermanagh, and late of Charlton, Kent.

OSBORNE.—On the 22nd ult., Mrs. Martha Osborne, relict of the late T. Osborne, Surgeon, of Northampton, aged 67.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 25th ult.:—Frederick Isaac Flower, Middlesex Hospital; Henry John Hunt, King's College Hospital; Arthur Long, Barham, near Canterbury; Thomas Mills, Cliff parade, Southend; Herbert Morris Spencer, London Hospital.

The following gentleman also on the same day passed his first examination:—John Comyns Leach, University College.

DEATH OF PROFESSOR CASPER.—This eminent professor of forensic medicine, whose work on this subject is translated into English and published by the Sydenham Society, died at Berlin on the 23rd ult. Dr. Casper was the first and the only one in Prussia who held a professorship in forensic medicine.

THE RIBERI PRIZE.—The Royal Academy of Medicine of Turin announces that this prize (the most magnificent in money value in existence) of 20,000 lire—nearly 1,000*l.*—will be adjudged to the author of the best work, whether in manuscript or published, which has been produced during the three years from the first of January, 1862, to the 31st December, 1864. Any subject in Medicine or Surgery may be chosen, the preference to be given to such work as exhibits a truly important progress in Medical science. The manuscripts or books must be written in Italian, Latin, or French, and of these last two copies must be forwarded. All works, which will become the property of the Academy, are to be delivered, free of expense, to Dr. Marchiandi, Secretary to the Academy, before the 31st of December; and their authors are requested to indicate the portions to which they most particularly wish to draw the attention of the Academy.

DEATH OF DR. JOHN JACOB, OF MARYBOROUGH.—With grief we have to record the death of this distinguished member of our Profession, and to express on the part of our brethren the regret they must entertain for the severe loss they have suffered by the lamentable event. His eminence as a provincial practitioner, his high character for independence as a member of our body, and his unflinching honesty, won for him a position in public estimation which cannot fail to sustain the reputation of those who are engaged in the pursuits to which he was specially devoted. He had been for some years in a precarious state of health from excessive labour in the discharge of his public duties, and has, in fact, fallen a victim to that spirit of determination and energetic devotion to the service in which he was engaged for which he was so remarkable. On a future occasion we hope to enter more largely into some detail as to the part he has taken in Medical affairs.—'Dublin Medical Press.'

TUNBRIDGE WELLS INFIRMARY.—At the annual meeting recently held a memorial was presented by upwards of a hundred subscribers, praying for the addition of fever wards to the institution. After a warm and long discussion it was resolved not to accede to the wishes of the memorialists. Is not this a mistake.

PRESENTATION TO PROVOST ADAMS OF LANARK.—On the 24th ult., the highly-respected Provost of the Burgh, Alexander Maxwell Adams, M.D., was presented, in the hall of the County Buildings, with a flattering testimonial of the great esteem in which he is held by his fellow-townsmen and the gentlemen of the neighbourhood, both for his eminent public services, long and faithfully rendered, and the surpassing worth of his character as a private gentleman. The tea service and salver, forming the presentation plate, are very fine specimens of the silversmith's art, and do great credit to the taste and skill of Mr. Cassels, who provided them. Upon the salver is the following inscription:—"Presented, along with a carriage and silver tea service, by a large number of the inhabitants of Lanark and its neighbourhood, to Alexander Maxwell Adams, Esq., M.D., Provost of Lanark, to testify their high appreciation of his public and professional services and private worth. 25th Feb., 1864." The gold brooch, also supplied by Mr. Cassels, is an exceedingly handsome and massive jewel of great value. The carriage, an elegant little one horse phaeton, from the factory of Mr. Stordy, stood at the door, while the company were leaving. When the Provost entered it, a few of the younger members of the party unharnessed the horse, and drew Mr. Adams home amidst loud cheering.

DEATH OF A MEDICAL MAN IN A SNOWSTORM.—Dr. Gallice, practising in Langeac (Haute Loire), France, perished in the snow, on the 20th ult., whilst returning on horseback from his country rounds. He might have been saved but for the stupidity of some people, who feared to assist him without the aid of the rural police!

DR. HATHAWAY.—We learn that one of the first acts of the new Governor-General of India has been to confirm the appointment of Dr. Hathaway as his private secretary, which has given satisfaction to all parties.

MURDER OF AN ITALIAN MEDICAL MAN.—Dr. Frediannelli, rural practitioner at Santa Croce, in the Val d'Arno, Italy, was stabbed whilst hastening to see a patient reported to be dying. The foul deed was perpetrated in the night from the 11th to the 12th ult., and the stiletto wounded the right common iliac artery and the right kidney. The assassin is said to have been arrested.

TESTIMONIAL TO A SURGEON.—Dr. R. B. Painter, of Brydges street, Covent garden, having, in consequence of removal to South Kensington, resigned the appointment of surgeon to the police at Bow street, was, on the 20th ult., presented by that body with a handsome silver inkstand, bearing the following inscription:—"Presented to Richard Budd Painter, Esq., M.D., F.R.C.S., also Surgeon to the F division of the metropolitan police for several years, by the officers, sergeants, and constables of that district, in appreciation of his excellent qualities, professional and private, and as a small token of their very great esteem for him. Thomas Durkin, Superintendent, Bow street, February, 1864." The presentation is alike honourable to both parties. Dr. Painter has been indefatigable in his duties, and during his period of office did the public good service on several occasions in which he was required as a medical witness.

THE DANISH CAMPAIGN.—Ten military surgeons have been sent from Vienna to bring back by train the wounded Austrians. There are at present in Schleswig, besides the regimental surgeons, fifty-four medical men employed in the hospitals.

PRESENTATION TO A SURGEON.—Dr. Hawkins, of Hitchin, was, on the 27th ult., presented with a magnificent silver salver and a thousand guineas. On settling at Hitchin, in 1820, Dr. Hawkins founded a dispensary, to which he attended single-handed for upwards of twenty years. Finding that the means at his disposal were wholly insufficient to supply the wants of the ever-increasing throng of patients attracted by his professional skill and by that winning kindness which, perhaps, is the true secret of his extreme popularity, Dr. Hawkins directed all his efforts toward supplying them with more effectual means of relief. He made an appeal to the wealthy inhabitants of the town, which was generously responded to, and the result was the erection in 1842 of the present infirmary. Until October last, when he was suddenly struck with paralysis from which he has not recovered, he unremittingly fulfilled the duties of surgeon to the institution; and it was to testify their gratitude for his lengthened services that the subscribers presented him with this splendid token of their regard.

NEW USES OF IODINE.—From the specification, recently issued, of a patent by Professor Hofmann, of London, a new colouring matter, which dyes silk and wool of a beautiful violet, blue violet, or a red violet tint, has been produced by the application of the iodine extracted from seaweed. It has long been thought if iodine could be used as a colouring substance it would be of the most powerful kind known. The patented process consists of mixing in certain proportions the substance called rosaniline with the iodides of ethyl, methyl, or amyl.

POISONING BY ABSORPTION.—An inquest has lately been held at Wissett, near Halesworth, Essex, on a child, aged nine years, to whose head had been applied some "white precipitate powder" to destroy vermin. The viscera had been submitted to Professor Taylor, who was of opinion that no poison had been taken internally; but that all the symptoms were consistent with the fact of the external application. Verdict accordingly.

PETROLEUM.—At a late weekly meeting of the Society of Arts, W. Marcet, M.D., F.R.S., read a paper on the Economic Value of Petroleum. This, with the discusson which ensued, in which several medical gentlemen participated, tended greatly to illustrate the necessity of caution in its use, and several valuable suggestions were made, which were calculated to lessen the danger which now exists in its employment.

REMARKABLE DEATH THROUGH A MEDICATED LOZENGE. On Wednesday week an inquest was held by Dr. Lankester, at the Lord Nelson, Upper Charlton street, Fitzroy square, on the body of a male child, aged three weeks, the son of John Mason, who died through the administration of a medicated lozenge containing the 48th part of a grain of morphia, by its mother, to alleviate a cough. The medical gentleman in the case stated his conviction that the death of the child was produced by the above-mentioned small dose of morphia in the lozenge, and related the case of a child a month old which had died from the administration of the 180th part of a grain of morphia. A statement having been made by an attendant for the manufacturer of the lozenges as to the quantity of morphia contained in them, the Coroner summed up, remarking that from what they had heard a warning was given that young children should not be given cough lozenges. The jury returned a verdict of "Death through Accidental Poisoning by Morphia."

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAR. 9. — *Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal College of Physicians, 5 p.m.—Lumleian Lectures: Dr. Barclay, "Fallacies in the Application of the Inductive Method of Reasoning to the Science of Medicine."

THURSDAY, MAR. 10.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Marshall, "On Animal Life," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

FRIDAY, MAR. 11.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians, 5 p.m.—Lumleian Lectures: Dr. Barclay, "Fallacies in the Application of the Inductive Method of Reasoning to the Science of Medicine;" Royal Institution, 8 p.m.—Rev. W. H. Brookfield, "On the Use of Books."

SATURDAY, MAR. 12.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, MAR. 14.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAR. 15.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Vindication of Aural Surgery. By a Member of the New Sydenham Society. London: John Churchill and Sons, New Burlington street.

A Practical Treatise on Diseases of the Skin in Children; from the French of Caillault. Second Edition, with Notes, Appendix and Formula. By R. H. Blake, Esq., M.R.C.S.E. London: John Churchill and Sons.

The Pharmaceutical Journal for March.

American Medical Times.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

We must request our Country Correspondents who favour us with copies of Provincial Newspapers, to mark the passages to which they desire to draw attention.

A VOICE FROM THE DRUG-ROOM.—The letter is inserted.

Dr. W. B.—The newspapers have been received.

R. H.—The depression of the anterior fontanelle in infants is symptomatic of general debility, and is produced by the vessels of the great cerebral mass not being duly filled.

V. P.—We are acquainted with three cases of dislocation forwards of the last lumbar vertebra. In 1850, Kiwisch recorded one case; in 1853, Kilian mentioned another; and the third was brought forward by Professor Spaeth, of Vienna. The history of the last is as follows:—A woman, aged 29, of middle height, in good condition, and with excellent development of limbs, neck, and bust; body bent backwards and lumbar region of spine unusually concave; abdomen prominent. Patient fell into labour, at commencement of which the fœtal head lay toward the left hip; os uteri could scarcely be reached by tip of finger and *last lumbar* vertebra was distinctly felt dislocated forwards. Labour being protracted, and rupture of the uterus feared, delivery was effected after perforation, and, though nothing abnormal occurred immediately subsequent to the birth of the child, the patient died of metro-peritonitis.

The pelvis is in the museum of the General Hospital, at Vienna. The conjugate diameter is 9" 5", the transverse 4" 9". These dislocations are considered to be *congenital*, no evidence of *injury* being discoverable.

We have received a box containing a preparation, called Myrrhine by the inventor, M. George, of Paris, and used as a dentifrice. As its name implies, it is prepared from the essential principles of Turkey Myrrh, and has the fragrant odour of that well-known gum-resin. It has the form of a cake, on which a moistened tooth-brush is passed, and then used on the teeth in the ordinary manner. Each cake is accompanied by a liquid preparation, also containing myrrh, and which is to be used for rinsing the mouth and moistening the cake. No acids or alkalies or any other substances likely to be injurious to the teeth are contained in either of these preparations, and from personal use we can pronounce them to be most agreeable and efficient adjuncts to the dressing-room table.

Dr. J. L. EARLE'S paper on "Post-partum Hæmorrhage and its Scientific Treatment," shall appear next week.

Dr. C.—The letter is inserted.

EXPERS.—The average time in which the body cools after death is about fifteen hours, but the period will be modified by various circumstances, as the mode of death, the temperature of the surrounding atmosphere, &c. In some few but well-authenticated cases, the temperature of the body has risen after death.

Dr. F.—We have expressed our opinion upon the subject in another part of our Journal.

Dr. KIDD'S letter is received, and is under consideration.

ARMY MEDICAL DEPARTMENT, March 1st, 1864.

A Competitive Examination for ASSISTANT-SURGEONS in HER MAJESTY'S ARMY will commence on MONDAY, the 21st instant, at ten o'clock A.M.

Candidates up to THIRTY YEARS OF AGE are eligible to attend.

Immediate application should be made to the Director-General of the Army Medical Department, 6 Whitehall yard, for the printed form which is required to be filled up before any name can be placed on the list.

J. B. GIBSON, Director-General.

Royal College of Physicians of LONDON.—THE NEXT PRELIMINARY EXAMINATION in the subject of GENERAL EDUCATION will take place on the 22nd and 23rd of March.

Candidates intending to present themselves for this examination are required to give notice in writing to the Registrar of the College.

Every Student is required to have passed an Arts Examination before commencing his Professional Studies, in order to qualify him for Registration at this College as a Medical Student.

H. A. PITMAN, M.D.

Pall Mall East, 1864. Registrar.

Wanted immediately by a Surgeon in a mining district of the North Riding of Yorkshire, a qualified out-door Assistant to visit and attend Midwifery, not under 26 years of age. A gentleman who would shortly enter into partnership on easy terms with a view to succession preferred.

Address, B. C. Post Office, Richmond, Yorkshire.

Emperor Life and Fire Assurance SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible or have altogether failed in effect. Imitations having arisen, be particular in the address.

Epilepsy.—Special Home for Children or the young affected with epilepsy. Established eight years. The importance of an early removal from the parental home, of those affected with epilepsy, to reside under the systematic care and physical and mental regimen of this home, has been strikingly shown in the cases received; children whose cases have been considered by their parents and physicians as almost hopeless, make a steady progress of improvement and recovery. The arrangements of a private family are maintained, with unremitting attention to domestic comfort. Address J. R., Carter's Library, Hampstead, N.W.

T. & H. Smith's Codeia Lozenges. These Lozenges have a remarkable effect in allaying COUGH, and IRRITATION of the THROAT and CHEST.

Prepared only by T. and H. SMITH and Co., 21, Duke Street, Edinburgh; and 69, Coleman Street, London; in Boxes at 1s. 1½d. and 2s. 9d. each.

New American Preparations.—W. TWINBERROW begs to inform the Medical Profession that he has had a large consignment (direct from Keith & Co., of New York) of ALL the MOST VALUABLE American Medicinal Preparations. Also—

EXT. CANAB. INDICA, direct from Calcutta.

PIERLLOT'S VALERIANATE of AMMONIA.

Manufacturer of the New Preparation of

PEPSINE with Wine—PEPSINA PORCI—Ditto VITULI.

PHARMACEUTICAL CHEMIST.

Edwards Street, Portman Square, and 59B Westbourne Grove, London.

Liquor Folii Ricini or Fluid Extract of the Palma Christi Plant, for increasing the Secretion of Milk in Suckling women.

Mr. GREENISH solicits the attention of the Profession to the above preparation, which is now in great demand.

Dose: One teaspoonful three times a day.

Prepared by THOMAS GREENISH, Chemist, 20 New st., Dorset-sq.

Fine Old Port, Twelve Years in Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clarets, 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints; 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts; 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

Of all the complications met with in midwifery of any importance, flooding after delivery is probably the most frequent. The frequency with which it occurs varies greatly in the practice of different practitioners, and is not altogether due to mere chance, but in a great measure to the method of conducting labour, and to the precautions employed, both during and after the completion of that process, *e.g.*, the Medical man who is hasty in removing the infant and the placenta, or in leaving the patient afterwards; who never puts on a binder; who confines his patients at the foot of the bed with the mattress turned up; who allows them to be delivered encased in the whole paraphernalia of women's daily dress, will meet with more cases of flooding than the practitioner, who, in a natural case of labour, uses every precaution which, in his opinion, tends to prevent that accident.

Flooding after labour is said to be more common in town than in country practice, and there is no doubt a great deal of truth in this observation, for the debilitating influences of a town life induce that relaxed and cachectic condition of the system which is so unfavourable to the regular and permanent contraction of the uterus. It occurs more frequently amongst the upper than the lower class, from the lazy and enervating life the former lead. It is more common in warm than in cold climates, from the excessive heat inducing muscular debility and increasing the rapidity of the heart's action. This fact teaches us a practical lesson, which we may turn to a satisfactory account in our own country—viz., that the lying-in-room should be kept at a moderate temperature, and the patient not too thickly covered. It is, again, more common in multiparæ than in primiparæ; in the latter, the uterus contracts in a firm and equable manner, as is shown by the absence of after-pains in the majority of instances after first deliveries.

In order to appreciate more fully the great frequency of this complication, we should bear in mind that post-partum hæmorrhage occurs under two different forms. It either comes on immediately after delivery, and flows in such quantity and with such rapidity that it places the patient's life in imminent danger, and requires urgent and skilfully applied measures for its arrest; or the flow of blood occurs in not a large amount at a time, but goes on in a continual drain until it produces all the symptoms of an undue loss of blood. It is not at all uncommon to find on making our first visit to a patient after her confinement, that she has "lost very freely," that she feels low, and that the pulse is more or less quickened. This latter variety is almost ignored by Medical men; in other words, they do not consider these cases worthy of the term of post-partum hæmorrhage. It is true that the draining of blood generally begins to cease before the patient can be said to be in actual danger, still there remain the debility and languor resulting from the loss of the vital fluid to be recovered from.

Flooding after labour has been divided into the two following classes: — Primary post-partum hæmorrhage, where the flooding has commenced immediately or within the first hour after delivery. Secondary, where the hæmorrhage does not occur until six hours after labour, but within the puerperal month (McClintock). True cases of secondary hæmorrhage are comparatively rare. I mean to say, that if a woman goes on for six hours after labour without internal or external hæmorrhage, it is decidedly uncommon for her to begin flooding afterwards. In the majority of the so-called cases of secondary hæmorrhage, probably the loss of blood has commenced within the first hour of delivery, but from want of proper attention on the part of the attendant, the flooding has not been discovered until the lapse of some hours, when the symptoms of a severe loss going on draw for the first time the attention of those around her. Such an instance is merely one of prolonged primary hæmorrhage. I will cite a case in point. It occurred in one of the public institutions of this country. A poor woman had premature labour brought on, on account of a tumour of obscure character situated in the recto-vaginal pouch. After delivery was completed, she was placed in bed and was considered to be in a fair state. However, on the next day she turned on her knees for the purpose of emptying the bladder, when a frightful quantity of clots rolled away from her, and before assistance could be obtained she was dead. No doubt it would be consolatory to term this unfortunate case one of secondary hæmorrhage; but I am afraid there need be no hesitation in saying that this was a case of primary internal hæmorrhage, which through some gross neglect was allowed to go on unsuspected for so many hours.

Flooding after labour is a distressing accident, inasmuch as it requires time to recover from its effects. We may attend a patient in a most tedious delivery, which may even end instrumentally; yet in many instances, in twenty-four hours it would be impossible for anyone to tell that that patient had undergone any unusual amount of suffering or danger; on the other hand, in a case of flooding, let us arrest the hæmorrhage and place the woman's life in comparative safety, there still remain the effects of the loss, and months generally elapse before they are entirely removed, while in very bad cases, the rosy hue of health is banished from the cheek for ever.

Besides the immediate danger arising from a large loss of blood, flooding renders a woman more liable to asthenic inflammatory diseases, such as uterine phlebitis, phlegmasia dolens, puerperal mania, etc.; and when the already weakened frame is attacked by diseases of so grave a character, it is, of course, less able to bear up against the force of the malady.

It is also one of those obstetric contingencies which requires a man to be thoroughly well up to his work, and to possess presence of mind, for as soon as it commences he must act for himself. It is of no use sending for further help unless the attendant does all he can to stop the loss until that assistance arrives. It is such an appalling accident that the most experienced practitioner feels anxious as to the result; and if that be the case, what will be the feelings of the medical attendant who meets with such a case, and does not know how to treat it efficiently? It is most likely he will lose his presence of mind, and either do nothing at all, or use but very inefficient means. Most of us probably have trembled in treating our first case. I have heard of a young practitioner who, meeting with a case of flooding, became so alarmed that he hurriedly intimated to the relatives that nothing more could be done, and left the house. Another surgeon was immediately called in, just in time to save the patient's life. I have known sad results accrue in four cases from ignorance, loss of presence of mind, and neglect combined. In two of the cases the placenta was adherent; no attempt was made in either case to remove the afterbirth, and of course all other remedies were futile, and while further assistance was sent for, the women died. In the other two, the presence of clots in the uterus was the cause of the hæmorrhage; no attempt was made to remove them, and both cases ended fatally before proper aid could be obtained.

We have been looking at present only at the gloomy and dark side of the question, but the effect of treatment in post-partum hæmorrhage affords us a ray of consolation

sufficiently bright to disperse all the thick and dark clouds which may have been gathering over the mind of the timid student or inexperienced practitioner. Notwithstanding that flooding after labour is a dangerous complication, prompt and scientifically applied treatment is very rarely unsuccessful in arresting the hæmorrhage and in saving the patient's life. Before I put into practice the various means which I shall describe when I arrive at the consideration of the preventive treatment, I was constantly meeting with cases of undue loss of blood, and, although I have come across some of the worst cases that could occur compatible with life, I have not yet lost a case. I do not say this in a spirit of boasting, but from a desire to show the student that he may be as successful if he chooses. On the one hand, I wish his mind to be thoroughly imbued with the grave importance of this obstetric complication both to life and health, that he may see the necessity of making himself master of the subject in all its bearings; on the other hand, I wish him clearly to understand that prompt and efficient treatment will, in the majority of instances, end in success, that in the hour of danger he may not lose his presence of mind which is so essential to enable him to act with energy and judgment.

Is a second opinion necessary in a case of flooding after labour? In slight cases, if the Medical man has confidence in himself, there is of course no necessity; but if the loss has been very great, or is very difficult to stop, even an experienced surgeon will find it greatly to his advantage to have another to share the responsibility with him for two reasons: 1. In bad flooding cases there is always more or less danger of the patient dying hours or days after labour, literally from anæmia. 2. Flooding is often looked upon with suspicion by the friends. They not uncommonly attribute its occurrence to some mismanagement of the Medical man. One says "he took away the afterbirth without waiting for a pain;" another, "he tore or left some of the afterbirth behind." To this last conclusion ignorant women often come, from the raw fleshy appearance of the uterine surface of the healthy placenta. The Medical attendant may have paid the best attention to his patient, and have done everything in a skilful manner, yet the relatives will find out, or rather think they have found out, something he did or left undone which brought on the hæmorrhage. "If Mr. So-and-so had attended her she would not have been in this state," and similar harsh expressions, not at all conducive in spreading the reputation of a Medical man, are freely blurted out with all the ignorant spite and electric velocity of a woman's tongue.

(To be continued.)

HOSPITAL REPORTS.

MIDDLESEX HOSPITAL.

CASE OF OVARIAN TUMOUR.

(Under the care of DR. HALL DAVIS.)

S. W., æt. 47, a widow, by occupation a cook, admitted into Northumberland Ward on July 28, 1863.

Personal description.—Is well formed, stout, and robust looking; dark hair and brown eyes; muscular development good.

Family history.—Father died, æt. 59, from an apoplectic fit (three days); mother died, æt. 51, at the change of life. (?) Had three brothers and one sister; one brother died from phthisis, and her sister in her confinement, æt 33.

Previous history.—Catamenia appeared at eleven years of age; has been in service as a cook; has had very hard work. Her husband died nineteen years ago. Has had one boy and three girls; boy died from hydrocephalus, and the two girls died of phthisis, and the third from pertussis. She states that her first and last confinements were very protracted, especially the last; and she was in more or less pain for three days and two nights: she suffered from fulness and great uneasiness in the abdomen, three months after the birth of her last child. Never has had flooding, and has always been perfectly regular as to the period of the return of the menstrual discharge, though there was not much of it at any time. Has gradually increased in size, and sometimes has been in great pain, so that she was obliged to leave her situation, and rest herself.

Present appearance.—The cyst extends above the umbilicus, more especially on the right side, and towards the left iliac region the tumour appears to be very solid; cutaneous veins are slightly more enlarged than usual. No projection of the uterus is perceptible in the vagina.

July 29th.—The sound passes into the cervix uteri only 1½ inch. Ordered

Pot. bromidi, gr. v.;
Liquoris potassæ ℥xv.;
Infusi quassiæ, ℥j., ter in die.

And

Pil. hydrarg., gr. iv.;
Extracti coloc. co., gr. v.;
Extracti hyoscyami, gr. ii., misce ut ft. pil. ij. hac nocte sumend.

July 30th.—About the same: the pills have acted well upon the bowels.

31st.—Feels pain over the right iliac region. To have applied cataplasma lini cum opio over the painful part.

9.30 pm.—Feels relieved.

August 3rd.—About the same; she measures forty-five inches round the waist.

5th.—About the same; but measures only forty-four inches round the abdomen.

6th.—Feels feverish and hot, with considerable thirst; and this morning her pulse is 115; she has head-ache and coated tongue. Ordered

Pot. bicarb., gr. xv.;
Liquoris ammon. acet. ℥j.;
Spt. ether. nit., ℥xv.; ter in die,

and to continue the haustus pot. bromid.

7th.—Rather better; being not so feverish; tongue is cleaner, and is moist; measures 44¼ inches. Continue haustus pot. bromidi, and to discontinue haustus pot. bicarb.

8th.—About the same. Tongue is white in the centre; has head-ache; hot and thirsty. Ordered haustus pot. efferves. quartâ quâque horâ, and

Pil hyd. et pil rhei co., aa. gr. iv., hac nocte.

9th.—Better in every way; bowels opened; tongue cleaner, and she is not so thirsty. Ordered

Pot. bicarb., ℥j.;
Haustus ammon. acet., ℥vj.;
Aquæ menthæ, ℥jss. ℥j. ter in die.

11th.—Tongue white, headache, and has pain down along the right leg, with redness on great toe and swelling. Ordered

Pil. hyd. gr. j.;
Ext. hyoscyam. gr. ij., omni nocte.,

the toe to be painted with iodine and collodion. To have broth diet.

Discharged when she had quite recovered from this attack.

CASE OF INFLAMMATION OF THE SAC OF FIBROUS TUMOUR.

H. B., æt. 57, a widow, admitted under the care of Dr. Davis, on August 10th 1863.

Personal description.—She is tall, thin, but healthy looking, and about five feet eight inches in height; with a countenance denoting her to be a high liver; muscles small and flabby; teeth irregular, and very much decayed.

Family history.—Her father died of cholera between seventy and eighty years of age; mother died aged 83, having been for many years a martyr to rheumatism. Her parents had sixteen children, of whom four only are living;

her brother had disease of the heart, and her sister a tumour in the womb, accompanied with dropsy.

Previous history.—The catamenia appeared when she was fifteen, scanty, irregular, and with great pain, was married at twenty-two, has had two children and three miscarriages in twenty-three years; has been a widow now for twelve years. Soon after her husband's death, she noticed that she was swelling in the abdomen, and consulted a medical man, who diagnosed uterine tumour, which he told her might occasion her very little uneasiness, but could never be cured. Four or five years ago she was treated at Guy's Hospital for the complaint.

After leaving that hospital, and having been told that she had "stone cancer," she was admitted into the cancer wards of the Middlesex Hospital, whence she was transferred to the Prudhoe ward under the care of Dr. Davis.

State on admission.—Fibrous tumour on the right side of the uterus, but not clearly discernible, whether internal or external to the organ. The point of the uterine sound enters freely, and turns towards the left side.

August 7th.—Before her admission under the care of Dr. Davis, Dr. Williams had ordered her

Pot. bromid., gr. x.;
Liq. pot., ℥xv.;
Tinct. hyoscyami, ʒss.
Infusi gentian co., ʒvij., ter in die,

and a sponge tent was to be passed into the canal of the cervix.

August 8th.—Ordered two bottles of soda water, to be given her daily, and also ʒiv. of wine.

Haustus ammon. acet. ʒjss. quartâ quâque horâ,
and a large linseed meal poultice having mixed in it
Liq. plumbi diacet et Spt. vini rect., ää ʒj.
to be applied over the site of the abdominal tumour.
She was likewise to have a lemon each day.

Aug. 11th.—℞ Pot. nit.
Pot. bicarb., ää. gr. x.;
Spt. ether nit.
Tinct. hyoscyami, ää ʒss.;
Mist. camph., ʒj. quartâ quâque horâ.
Continue cataplasma lini.; wine, ʒiij.

August 12th.—Repeat.

August 14th.—Hirudines octo abdomini;
Rep. Cataplasma lini. cum opio;
Rep. Haustus pot. nit.;
℞ Hydrarg. chlor. gr. ss.;
Pil. saponis, co. gr. ij., quartâ quâque horâ.
Enema amyli cum tinct. opii, ʒj., statim.
Ordered to have custard pudding daily.

August 16th.—The enema having returned a short time after having been given, an anodyne draught was administered. Ordered to have an egg daily.

August 17th.—Vini xerici, ʒiij. Omit Pil.
℞ Tinct. hyoscyami, ʒj.
Decocti cinchonæ, ʒj., sextâ quâque horâ.
Ordered fried sole and two pints of milk daily.

August 21st.—Complains of great pain down both legs, which look somewhat swollen; there is an erythematous blush going down the skin on to the dorsum of the foot.

Limb to be wrapt in cotton wool, and to be bandaged. Continue draught.

August 25th.—Uterus enlarged, os retroverted, no nodular projections in the vagina.

Vini xerici, ʒjss. Repeat haustus cum cinchonâ.
Ordered two pints of milk daily, some rabbit, and an egg daily.

August 27th.—Complains of spasms; also great pain across both insteps extending up to the knee. The limb to be kept enveloped in the cotton wool and the bandage.

Repeat haust. cum spt. eth. chlor., ℥viij.

Pulv. calaminæ to be powdered over the malleoli.

Aug. 27th, 2 p.m.—Os uteri far displaced to the left side of the pelvis; no projection of cervix into vagina; uterus felt to be much enlarged, apparently by some internal growth. As the patient would not submit to the treatment deemed advisable, she was discharged.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. VI.

ACIDUM HYDROCYANICUM DILUTUM.—Considerable differences existed in the strength of this acid as ordered in the Pharmacopœias of the London, Edinburgh, and Dublin Colleges. The Hydrocyanic acid of the London Pharmacopœia contained 2 per cent. of real acid; that of the Edinburgh Pharmacopœia contained 3.98 per cent. The Dublin acid was a little stronger than the London acid. The Acidum Hydrocyanicum Dilutum of the British Pharmacopœia contains 2 per cent. of real acid; it is, therefore, the same acid that was ordered by the London College.

The process for its preparation is also practically the same that was given by the London Pharmacopœia. It consists essentially in distilling a mixture of a solution of Ferrocyanide of potassium with dilute sulphuric acid. Under these circumstances, one-half of the cyanogen contained in the salt passes over as hydrocyanic acid. In carrying out the process it is necessary to adopt efficient condensation, and to this end it is proper to put a portion of water into the receiver at the commencement. We are also ordered in the Pharmacopœia to reserve three ounces of the water; and at the end of the distillation to add to the product as much of it as may be required to bring the acid to the proper strength of 2 per cent. The London College directed six ounces to be reserved for this purpose; but in working with the exact quantity of material ordered, it was rarely, if ever, necessary to add any of it to the product; for the distillate generally contained almost exactly the 2 per cent. of real acid.

Manufacturers of this acid on the large scale, put much less water into the still than the Pharmacopœia indicates, and they thus obtain a highly concentrated acid, which can be diluted to the required strength.

The reaction which occurs during the distillation is somewhat complicated. The late Mr. Everitt, who carefully investigated this subject, showed that at the end of the process, there is left in the retort a peculiar yellow salt, which contains three atoms of cyanogen, united with two atoms of iron and one of potassium. According to this chemist's experiments, the change which occurs may be represented by the following equation:—

$$2\,(K_2\,Fe\,Cy_3) + 6\,SO_3HO = (K\,Fe_2\,Cy_3) + 3\,(KO,HO,2SO_3) + 3\,H\,Cy.$$

Ferrocyanide Potassium. — Yellow salt. — Bisulphate Potash.

This action, however, can only take place in the presence of a certain amount of water; hence the process is only

applicable to the preparation of a solution of hydrocyanic acid in water. When dry ferrocyanide of potassium is heated with concentrated oil of vitrol, no hydrocyanic acid is obtained, but the salt is broken up into the sulphates of iron, potash, and ammonia, and pure carbonic oxide gas is evolved. Anhydrous hydrocyanic acid may be obtained by heating the dry crystals of cyanide of mercury in a gentle stream of sulphuretted hydrogen. Sulphide of mercury, and hydrocyanic acid are formed, and the latter may be condensed by a freezing mixture ; but the operation is attended with considerable danger to the operator, from the escape of gaseous hydrocyanic acid.

Hydrocyanic acid, although as dilute as the Pharmacopœia acid, is very apt to undergo a peculiar change by keeping. Even when carefully kept from the action of the light, it becomes dark coloured, and is eventually converted into a brown pasty mass. The chemical nature of this change is not well understood; the black substance contains the same elements as the Hydrocyanic acid, and is named paracyanogen, but Formic acid, Ammonia, and other products are also present. The acid varies considerably in its susceptibility to this change. Sometimes bottle after bottle will spoil in the course of a few weeks, while in other cases the acid may be preserved unchanged for a great length of time. It has been commonly observed that Hydrocyanic acid, made by the Pharmacopœia process, keeps better than that made by other means. This was ascribed by Mr. Everitt to the presence of a minute trace of mineral acid. He found that the addition of a single drop of Hydrochloric acid to a large bulk of pure dilute Hydrocyanic acid preserved it from decomposition; although the presence of a larger quantity of the mineral acid rather favours decomposition than otherwise. The blackening of the acid is very much promoted by exposure to light ; and hence arose the custom of selling Hydrocyanic acid in dark blue glass bottles ; but this precaution is of little use ; for the actinic or chemically active rays of light are found closely associated with the blue rays of the spectrum ; consequently, the blue glass offers no obstruction to their passage. Some manufacturers, however, have recently taken a hint from the photographer, nd have adopted yellow glass bottles for the preservation of those chemicals which are liable to change by light. The yellow glass entirely excludes the blue end of the spectrum, and, therefore, cuts off the actinic rays. As far as Hydrocyanic acid is concerned, this practice has been attended with success.

So much inconvenience has at different times been experienced by the spontaneous decomposition of this acid, that means have been suggested for its extemporaneous production as required. One very convenient method of effecting it consists in taking 100 grains of crystallised tartaric acid in powder, 44 grains of cyanide of potassium, and 2 ounces of water ; shaking up in a bottle ; allowing the precipitated acid tartrate of potash to subside ; and then decanting off the clear liquid. It contains almost exactly 2 per cent. of Hydrocyanic acid, and is only contaminated with a very little saline matter.

Hydrocyanic acid is known by its remarkable odour, and it may also be recognised by three tests. With solution of Nitrate of Silver it gives a white, curdy precipitate, much resembling Chloride of Silver, from which it is distinguished by being soluble in moderately strong, boiling, Nitric acid. When mixed with a solution of a protosalt and a persalt of iron, then with some caustic potash, and finally acidulated with Hydrochloric or Sulphuric acid, it gives a precipitate of Prussian blue. When mixed with a few drops of Hydrosulphate of Ammonia, and the mixture evaporated to dryness upon a water bath, the residue gives with a persalt of iron a blood-red colour.

The British Pharmacopœia directs that hydrocyanic acid shall give no precipitate with chloride of barium, and that with nitrate of silver it shall give a white precipitate entirely soluble in boiling nitric acid. These tests are intended to indicate the absence of sulphuric and hydrochloric acids. The London Pharmacopœia gave the iodo-cyanide of potassium and mercury as a test for the presence of mineral acid. This salt is decomposed with formation of the red iodide of mercury when brought into contact with an appreciable trace of a mineral acid. This test possessed some advantages over those given by the British Pharmacopœia, for the inexperienced operator may fail in entirely dissolving the cyanide of silver in nitric acid, and thus be led to an erroneous conclusion. The strength of hydrocyanic acid is to be determined by a volumetric solution of nitrate of silver. The Pharmacopœia gives the following directions :—"Half a fluid ounce of the acid when treated with an excess of solution of soda, requires the addition of 80·66 measures of the volumetric solution of nitrate of silver before a permanent precipitate begins to form, which corresponds to two per cent. of anhydrous acid." The action of the test is as follows :—When the acid is treated with caustic soda, cyanide of sodium is formed ; and when nitrate of silver is added to this, the cyanide of silver first formed unites with the cyanide of the alkali to form a definite double salt which is soluble. The change is thus represented :—

$$2\,(Na\,Cy) + Ag\,O,\,N\,O_5 = (Na\,Cy + Ag\,Cy) + Na\,O,\,N\,O_5$$

When a permanent precipitate forms it indicates that all the alkaline cyanide has been converted into the double salt, and that the latter is in its turn being decomposed by the nitrate of silver. It therefore indicates the termination of the above reaction.

LONDON MORTALITY.—From a Parliamentary Return it appears that for all England and Wales the average annual mortality during the ten years, 1851—61, was 22·17 per 1000. In the Farnborough district in the south, and in Bellingham and Rothbury in the north (Northumberland), the annual mortality averaged less than 15 in the 1000. The metropolitan returns, corrected, give the annual mortality within the walls as 2222 to every 100,000 living. For the metropolis generally, including the suburbs, the ratio was 2,363.

THE ARMY MEDICAL SERVICE.—The return of the supplementary army estimates for 1863·4 has just been published. The estimated outlay of the medical establishment and supplies for the year is 15,900*l*.

REVIEW OF THE PERIODICALS.

The 'Lancet.'

Dr. W. T. Gairdner commences a series of clinical papers, the first of which is a very able and interesting communication entitled, "Facts and Conclusions as to the Use of Alcoholic Stimulants in Typhus Fever." Dr. Gairdner's object is to show that the routine system of treating typhus fever by excessive doses of alcoholic stimulants, is attended by more harm than good, and he argues that the late Dr. Todd's views on this point were, in the first place, not original, but derived from Dr. Alison, and in the second place, that they were formed without any discrimination as to the type of the disease in which the stimulants were beneficial. He proves by a careful examination of tabular statements, that the mortality from fever was the highest where the greatest amount of alcoholic stimulants had been used, and he, therefore, concludes that there would not only be a great pecuniary saving to the hospitals if the present plan were modified; but that the results of the treatment would be more successful. He does not, however, condemn the use of these agents altogether, or express an opinion in favour of reverting to the former plan of depleting in typhus; on the contrary, he admits that a moderate and watchful administration of tonics and stimulants (the alcoholic class included), is the best plan of treatment, but he thinks that the age, the previous habits, and the nature of the constitution, should be carefully studied in each case, and that especially in very young persons, stimulants should very rarely be administered except in minute and experimental doses. He is persuaded, from the results of observation, that stimulants are actively poisonous and destructive to the young in typhus, and very probably in most other fevers. Mr. George Pollock, in answer to a paper by Mr. Henry Thompson, in the 'Lancet' of Feb. 20, entitled, "Lithotrity without Injections," states that Mr. Thompson's plan has long been adopted by himself in the wards of St. George's Hospital, and in private practice, as the injection of the bladder has appeared to him to be superfluous and irritating. He also doubts the originality of Mr. Thompson's suggestion that previously to the operation the urine should not be withdrawn, as he himself has not thought it expedient to do so, and he believes that other surgeons concur in the propriety of leaving the urine in the bladder. Mr. Pollock quotes the authority of Sir Benjamin Brodie as to the general safety and simplicity of the operation of lithotrity, and he mentions that out of 115 cases operated upon by that distinguished surgeon, only five died from the operation itself. Dr. J. Henry Bennett contributes a paper on the "Hypodermic Treatment of Uterine Pain," and relates some cases in which this treatment was beneficial. He employed an aqueous solution of acetate of morphia, introduced beneath the skin by a moderately-sized steel needle or canula. The injection may be made in any region of the body, but Dr. Bennett has principally chosen the præcordial region for uterine and general pain, and for local neuralgia a spot as near the affected region as possible.

The 'Medical Times and Gazette.'

Dr. Garrod continues his "Lectures on the British Pharmacopœia," commenting upon a variety of articles which have been recently introduced into Medical practice. The new anthelmintics are Male Fern, Kamela, Kousso, and Santonica, the last being, perhaps, the most important, especially when used in the form of Santonin. Cherry-laurel water is an introduction of more than questionable utility. Bromide of potassium appears to be useful in some excited conditions of the nervous system, and bromide of ammonium (which is omitted in the Pharmacopœia), possesses analogous properties. Among the arsenical preparations, chloride of arsenic has been omitted, and the arseniates of soda and of iron have been introduced. Arseniate of soda is said to be analogous in its operation to phosphate of soda, and to produce the good without the bad effects of arsenic upon the system; but arseniate of iron is of very doubtful efficacy. Dr. J. W. Ogle relates a "Case of Traumatic Tetanus, in the Treatment of which Nicotine was exhibited." The employment of nicotine, or tobacco, in tetanus, may be theoretically supposed to be beneficial, and indeed nicotine has been employed in this disease by Mr. Savory and Mr. Simon, on the recommendation of Professor Haughton, of Dublin. Dr. Ogle, therefore, employed it in the case which he now describes, and which was that of a girl of fourteen years of age, who had received a severe lacerated wound in the left leg, followed by tetanus. Pounded ice was applied to the spine without any benefit, and at last nicotine was employed by subcutaneous injection, after being administered internally without effect. The preparation used was a solution of the strength of half a grain to ten drops of water, four drops being given at a dose. The treatment was unsuccessful, although at one time Dr. Ogle thought there was some slight amelioration of the symptoms. Dr. James Edmunds relates a "Case of Supposed Emprosthotonos, cured by the use of Ice to the Spine." The nature of the disease was somewhat doubtful, but relief was obtained by the method just indicated, and the patient recovered. She was a married woman, and the disease was not traumatic.

The 'British Medical Journal.'

Mr. Brodhurst continues his "Lectures on Orthopædic Surgery," his present subject being the "Curvatures of the Spine." The treatment of such cases is constitutional, and mechanical, the latter being the more important. Mr. Brodhurst recommends spinal instruments to be worn by the patient or to be fixed to a couch, and in severe cases of distortion he recommends both plans to be adopted alternately. Dr. A. T. H. Waters continues his "Lectures on Certain Mutual Relations of Physiology, Pathology, and the Practice of Medicine," and in reference to therapeutics he speaks in eulogistic terms of the employment of alcoholic liquors, both in the treatment of disease and as ordinary beverages, taken in moderation. Dr. Waters also remarks that drugs are often employed in too small doses, and he mentions a case of chylous urine treated by himself, in which he employed gallic acid without any good effect until he largely increased the dose when the symptoms disappeared.

REVIEW OF BOOKS.

An Essay, Historical and Critical, on the Mechanism of Parturition. By William Leishman, M.D., Physician to the Glasgow University Lying-in Hospital, &c. Pp. 129. London: Churchill and Sons. 1864.

The substance of this essay has already appeared as a series of papers in a Scottish Medical periodical, and we have had occasion to notice them in terms of approbation. In their present collected form, they constitute a very useful contribution to obstetric medicine, and will be read with great interest. The essay exhibits extensive research combined with practical knowledge, and its subject-matter is spread over a wide space of time, from the theories of Hippocrates to the *vexata quæstio* of the present day, of supporting the perinæum in labour, of which practice Dr. Leishman is a decided opponent. The scope of the work comprises two distinct objects, the first of which is to describe the history of the rise and progress of the obstetric art, and the second to trace the mechanism of parturition in its different stages. The latter part, which is necessarily limited in its nature, as it does not comprehend the phenomena of præternatural labours, is nevertheless replete with interest and instruction, inasmuch as the stages of natural labour, however well they may be understood at present, have been in former times the subject of much doubt and misapprehension. The full understanding of the normal process of parturition is a most important element in obstetrical studies, and we have no hesitation in strongly recommending Dr. Leishman's essay to the notice of the Profession. It is illustrated by a few very well executed engravings.

Functional Diseases of Women; Cases Illustrative of a New Method of Treating them through the Agency of the Nervous System by means of Cold and Heat. Also an Appendix containing cases Illustrative of a New Method of Treating Epilepsy, Paralysis, and Diabetes. By John Chapman, M.D. Pp. 74. London: Trübner and Co. 1863.

In a paper published by one of our Medical contemporaries last summer, and which we fully noticed at the time of its appearance, Dr. Chapman proposed a new and peculiar method of treating some convulsive diseases by means of the application of cold and heat to the spine. The method he recommends is to employ alternately hot water and ice, each in an India-rubber bag, along the portion of the spinal column containing the part of the cord in which he wishes to act, and the theory which he suggests is, that the stimulus thus applied to the spinal cord acts upon the sympathetic system, by controlling the action of its blood-vessels, and thus regulates abnormal conditions connected with what is termed reflex action. It is impossible to give a brief abstract of the ingenious reasonings by which Dr. Chapman supports his theory, or of the multifarious cases to which his plan is applicable, and it is the less necessary to do so, as we gave in our number of July 22nd of last year a condensed notice of his original paper, which is moreover incorporated, in the form of an appendix, to his present pamphlet. It is only necessary to state here that he has carried out the same treatment which he has found efficacious in epilepsy and other allied affections, to the maladies peculiar to women, such as defective and painful menstruation, leucorrhœa, menorrhagia, and the like, and his reasoning is, of course, analogous, because the uterus is especially under the control of the ganglionic system, and therefore amenable to any treatment which powerfully affects the vessels of the sympathetic. The treatment proposed is entirely new, and the theory on which it is founded is not only original but actually opposed to some late views of nervous action, but still the results obtained by Dr. Chapman are so striking as fully to merit further investigation; and although we ourselves have no practical knowledge as yet of the efficacy of the means proposed, we shall be most happy to learn that they have met with the success which Dr. Chapman anticipates.

GENERAL CORRESPONDENCE.

A WORD ABOUT OUR LECTURE SYSTEM.

To the Editor of the Medical Circular.

SIR,—By the perusal of your leading article of last week, we are again reminded of a question that has long weighed on every one who has thought about our Medical Education—is the system that we have now in such busy action the right one? We have at this moment some of the best lectures in the world under delivery, with the largest variety of enforced courses, but as we examine the students who hear them, or test them as they emerge amongst us as practitioners, can we say that we are lecturing them into safe surgeons or sound physicians? As matters of fact we find that they cannot dispense with the help of the grinder when thinking of facing the Colleges and that, once passing that ordeal, the bedside shows them far better acquainted with the nomenclature of disease than the form of it that is inviting their assistance. Yet there has been no lack in the amount of their teaching, or in its quality—such teaching as it has been—and we are not of those who question the industry or talent with which these students have been seeking to turn it to the best account. The question then arises, if well educated young men of fair ability, after so many years study, come out so often a failure under such circumstances, is the result their fault, or that of the system? The truth must be owned—and with all the more conviction, as we have the more experience, that this excessive lecturing system of ours is all a mistake.

We cannot lecture men into a practical knowledge of anything, and least of all of a complicated, vast, and eminently practical science like ours. The ear is one of the least imperfect organs of our knowledge, and of all aids, the weakest to that kind of knowledge which claims to deal with the subtle lethal agencies under which our frames tend to disease and death. The student, who has heard his three or four thousand lectures has, no doubt, received certain impressions about all the subjects discoursed upon, but what is the value of all these impressions as an adjunct to practice, or even as an aid to learning? Were any psychical dissection possible of the brain of one of these unfortunate young men on the close of a year's studies, what a singular confusion and interlacing of all sorts of hues and forms of judgment, opinion, and conjecture should we have revealed to us? How many vague, absurd, and mischievous impressions about organic structure, vital functions, morbid action, therapeutic and other agencies, would there be set against a single sound view of the nature of disease and of the true plan of ascertaining its character and meeting its requirements? We have talked at him and to him, to the best of our ability, but all the super-excellent learning we have been ding-donging into his ears has been but as the impressions won from tinkling brass, or sounding cymbals. The nine-tenths of our discourses have been in an unknown tongue to him, and have conveyed anything but the impressions from whence they had proceeded in ourselves. The confused ignorance he had before on the subject we have worse confounded; and, perhaps, our success in this way has been all the greater in proportion to the pains the poor fellow has been taking, and the excellence of his memory. The more he carries away, the less he knows what to do with it; and if there were any question of a practical application of his knowledge, it would certainly not be the professor knowing anything about him who would offer himself as the "vile corpus" inviting the first experiment.

The mistake we have been making is one common of late years to most other professions. We have been yielding too much to the modern temptation to philosophise in

our Medical education. We have been seeking to make the humblest of our practitioners as accomplished theorists as the rare men of genius who have devoted to theory the best part of their lives, and we have been thinking nothing done in the most practical of professions unless we had first initiated its students in all the abstruse mysteries of abstract or transcendental science. We have filled their minds with all that they may never, perhaps, apply, and left to accident their having or using the opportunity by which they may acquire the knowledge which will be always in request from them, and which unknown will mean suffering and death to thousands. It has been all teaching and little or no learning. The lore of the profession has been made to abound above measure; and all our twenty-lecturer power of cramming it into the intellectual stomach fails in obtaining for it either a healthy digestion or useful assimilation. The general run of practice is no safer now, with all our undoubted advances in science than a hundred years ago, and while the extent and excellence of our medical literature would suggest that nobody need die of disease, we have only to look at what is taking place about us to have an uneasy suspicion that no more die of disease, and not less of the doctor, than ever.

We must try, then, in our education to get rid as soon as possible of all this over-theorising and under-practising. We must have a good deal more of the hospital and a great deal less of the lecture room. We must revert to the system, we might say the want of system, which has given practical medicine its greatest luminaries,—Hippocrates, Galen, Boerhave, Sydenham, Abernethy, Astley Cooper, and Brodie. Students in one form or another must be trained as the apprentices rather than the pupils of the science. Taken away as much as possible from the French plan of theorising on a subject, they should in a like proportion be brought into practical acquaintance with it. We must have more clinical clerks, more dressers, more house-surgeons, and more house-physicians, and the hospital, not the university, must be made the alma mater of the candidate for membership. We must arrange that his home, his workshop, his study shall be there, and there only, except so far as it may be found in the house of a practitioner out of whose abundance of knowledge and experience every familiar word and act must mean an imparting of practical knowledge. The true secret is for the young men to acquire a thorough acquaintance with the workings of disease by their own observation of it, to know it so well that they may be familiar with it in all its phases, able to decipher it in all its susceptibilities, contingencies, and necessities, foresee its coming history, and charged with the data which indicate its true nature, give a probable judgment on the appliances best fitted to deal with it. A learned nomenclature never yet saved a patient, and never will. Where one of the multitudinous mischances to which civilised humanity is heir to has laid low the strong man, and some obscure form of fever comes in to complicate the symptoms, of what use to bring to his bedside the young practitioner whose head is laden with the memory of a thousand extraordinary cases in which phenomena more or less unlike were met by as many forms of treatment as there are pages in the new Pharmacopœia, and about which his actual knowledge is in the inverse ratio of the extent of the impressions he had been receiving about them. The picture is there to tell him everything if he has the eyes made learned by experience, to read the interesting mystery; but for him it is like the doubted work of an unknown master to some first year's student on the benches of the Royal Academy, albeit the one is as decipherable to the eyes of an able practitioner, as the other to those of an accomplished connoisseur.

Away, then, with this upside down, this wrong end first mode of teaching medicine! Let us have surgeons and physicians who learn, rather than surgeons and physicians who are taught, men who have seen rather than heard, who have practically observed rather than heard described, men, in fine, at home with disease rather than with the books or lectures that speak about it. It is only in this way we shall ever again have another Sydenham or another Hippocrates.

I am, &c.,

VIGIL.

"GRATUITOUS MEDICAL SERVICES."

To the Editor of the Medical Circular.

SIR,—On reading your article in to-day's CIRCULAR with the above heading, which contains more good sense in small compass than I have seen for many a day, I am induced to send you an almost *verbatim* report of a short conversation I had with a brother practitioner a few weeks ago.

The want of combination amongst Medical men to *force* the public to put a proper estimate on our services, is keenly felt by the great body of general practitioners, both in town and country, men working not merely from "morn to dewy eve," but from dewy eve to morn again; men who by the hardest mental and physical toil, in many instances, can only just make ends meet.

Perhaps, I belong to a class a little more fortunate, and yet from *bitter* experience I have felt the worth of every word of your leader of to-day, when you allude to the abuse of Medical charities.

On one point will you excuse me for saying, I think you are in error; you appear to be under the impression that in rural districts matters are better, and between the operation of the Poor-law and benefit societies that there are fewer evils to complain of. I am not going to remark upon the miserably small salaries doled out by niggard hands to the Poor-law surgeons, nor of that large class in every district just above pauperism, who never think of paying the doctor, nor yet of the very small sum paid by benefit societies to their Medical officers; but I wish to say a word about the indirect frauds practised upon the Profession by these said "benefit" societies, which frauds, by the bye, would never be attempted, if we were a more united body. In many instances, it is a fact that these societies are largely supported by a class of men who do not need them, and as an insurance against sickness; and in fact, when sickness comes never avail themselves of the funds. They openly join these societies, nay they are invited to do so for the sake of the doctor's services, for which this "*victim*" receives 2s. 6d. per annum.

I believe it quite true that many of these clubs or societies are founded on very incorrect bases, and are kept from bankruptcy by such members as these—that is, at the expense of the brain, bone, and muscles of the Medical man—a practical proof of the injustice we inflict on ourselves by our want of combination. Is it not from the same cause that we are compelled to accept such miserable remuneration from these societies, particularly from those whose operations are on a large scale.

The following brief colloquy thus illustrates these points:

MR. A.—Good morning, Mr. B. I am very glad to see you, but are you not poaching on my preserves? I am about visiting a patient in the very house you have just left.

MR. B.—Don't be alarmed, my dear sir, I would not injure you if I could. The fact is, I have been visiting your patients on behalf of a society for which I am acting as Medical superintendent.

MR. A.—Then, Sir, I hope you are well-paid for your *four* miles walk this morning.

MR. B.—No, indeed, for this particular visit, and for filling up the weekly certificate, I receive something less than THREEPENCE, but I suppose if I refuse to do so, then I should lose the appointment of Medical examiner, which pays rather better, though not much.

Now, Sir, this from a respectable, middle-aged man, an M.R.C.S.E. and L.A.C., speaks volumes.

I, for one, feel grateful for your advocacy of "*combination*" in your leader of to-day, and does not the "body" of the Profession, whose time is absorbed in earning their daily bread, look up to those men who constitute the "head," to bestir themselves in this matter. When we are true to ourselves, the public will respect us, but until we are a *united body*, we shall never be able to obtain the just reward for our labour, and secure the position due to us as members of a liberal profession.

I know this is a very old grievance, but pray, Sir, follow up the subject so ably discussed in your leader to-day. It must do good.

I am, &c.,

"A WORKING BEE."

THE MEDICAL CIRCULAR.

WEDNESDAY, MARCH 16, 1864.

MEDICAL EDUCATION.

In discussing the subject of Medical education, it is necessary to examine the different systems pursued in the Medical schools of each division of the United Kingdom, and the courses of study laid down by the whole of the Examining Boards. By confining our attention to one school, or to the curriculum laid down by one Examining Board, we should fall into the same error as that which Mr. Syme committed, when he supposed that his remarks, which are really applicable only to the University of Edinburgh, are pertinent to the state of Medical education throughout Great Britain and Ireland. A somewhat similar mistake is made by the writer of a very fair and candid article in one of our Medical contemporaries, who, though professing to treat of Medical education in general, limits his observations to the London Schools of Medicine, and to the requirements of the London College of Surgeons, and the Society of Apothecaries.

Again, in a letter signed VIGIL, which we print to-day in our own columns, our respected correspondent refers to a state of things which has either passed away altogether, or exists only in certain schools. When he writes about the three or four thousand lectures which the supposed student has attended, he certainly draws largely on his imagination, as no such number of discourses is enjoined by any of the English Examining Boards. To take, for instance, the University of London: that body merely requires that a candidate for the degree of M.D. should attend, during about six years, five courses of lectures, which, even supposing that each course consisted of 100 lectures, would make altogether 500. The College of Surgeons of England requires the student to attend lectures on Anatomy during two winter sessions, on Physiology during two winter sessions, and on Surgery during two winter sessions, besides one course of lectures, respectively, on Chemistry, Materia Medica, Medicine, and Midwifery. Now, the whole of these lectures, supposing them to be all attended, and which are or may be spread over a period of four years, amount to about 700, taking the average of the number of lectures delivered at each school during the session. The requirements of the Society of Apothecaries and those of the College of Physicians (in the case of the licentiates of the latter body) are pretty much the same, the Society of Apothecaries omitting Surgery, and adding Botany and Forensic Medicine. Thus the whole number of lectures which a student is usually required to attend to obtain a qualification in medicine and surgery is considerably under 1,000, which may still seem a large number, but when spread over a period of four years, or 1,460 days, is really nothing very monstrous, except, perhaps, to those who disapprove of lectures altogether as a means of instruction.

To this class of objectors it is not very easy to reply, except by the remark that if lectures are to be abolished, it is difficult to understand what mode of instruction can be substituted in their place. It may indeed happen in certain isolated cases that some student may work out his own course of study for himself, may find out the books he ought to read, and the precise parts of those books he ought to select for especial meditation; may discover, by woodcuts and illustrations, the forms of drugs and chemical instruments, or may perhaps perform chemical and physiological experiments for himself, as many illustrious philosophers have done before him; but we repeat the remark we made last week that the great majority of students, under such a plan, would waste days and weeks and months in profitless toil, and, in most instances, would abandon in despair the attempt to reduce into order the chaotic mass of materials placed before them. The duty of the professor or lecturer is not to exhaust his subject by long-winded disquisitions on theoretical points, but to indicate to his pupils the leading doctrines of the science which he teaches, to direct attention to the best books which ought to be consulted, and if his subject is a practical one, such as anatomy, chemistry, or natural history, to illustrate by experiments, diagrams, or objects, the facts and doctrines which he inculcates. Supposing a lecturer to perform his duties in this spirit, and to be possessed of ordinary zeal and intelligence, we are at a loss to understand how his exertions can be otherwise than beneficial, and indeed we cannot divine any better plan for the communication of practical knowledge from one human being to another.

But it is undoubtedly true that the best of lectures are only means to an end, that end being to draw the outlines of science which the student's mind must subsequently fill up, and to indicate the use he ought to make of his hands, eyes, and ears. In a practical calling like Medicine it is, of course, essential that the senses should be called into requisition; that patients should be seen and handled, their chests listened to by the stethoscope, their eyes viewed by the ophthalmoscope, their throats by the laryngoscope, their urine examined by chemical tests, and their medicines properly selected, prepared, and administered. In the department of Surgery, the student must learn by frequent operations on the dead body the mode of operating on the living, and must make himself practically conversant with the application of plaisters, splints, and bandages. Any person, therefore, who proposed that these matters should be taught by the delivery of oral lectures alone, or by books, would commit a grievous mistake, and we venture to assert that no such mistake has been made by those who direct the courses of Medical and Surgical study in this country. Many years ago it was, indeed, the custom to require little more than evidence of having attended lectures on such and such subjects, and the examinations for licences and diplomas were conducted almost exclusively by conversation. But a person who should affirm that this system is pursued or encouraged in the present day would no more represent the true state of

affairs than one who asserted that mammoths and mastodons now roamed along our plains, or that icthyosauri swam upon the surface of our lakes. In fact, almost every part of the requirements issued by the examining boards has a practical tendency. One enjoins that the student must have engaged in practical chemistry and practical pharmacy, another in practical medicine and practical midwifery, and all, without exception, insist that he should dissect the human body; and the examinations held by the different licensing boards are all of a more or less practical character. At one the human body is dissected, and the student is required to demonstrate the structures exposed; at another he is required to perform chemical tests, or to explain microscopic objects; at another, he explains the symptoms of disease on a living patient; at another he applies, in the presence of the examiner, bandages or splints to an injured limb.

The means of practical instruction at all our hospitals and Medical schools have been multiplied of late years to an infinite extent. Magnificent museums present an unlimited field for the observation of healthy and morbid structures, and the arts of drawing and colouring and modelling in wax appeal, with even greater distinctness than Nature itself, to the cognisance of the senses; chemical laboratories, with all the appliances of modern science, offer ever new facilities for the analysis of organic and inorganic bodies; and long ranges of sick wards invite the student's attention to the living phenomena of disease.

Now the question arises whether the students of the present day avail themselves, to the extent they might do, of the countless advantages thus liberally presented to them; and the reply, founded in our own case on inquiries made in various trustworthy quarters, must, we fear, be in the negative. We challenge contradiction when we assert that in some of our largest hospitals, presenting almost unlimited opportunities for study, the physicians and surgeons are actually unable to procure a sufficient supply of clerks and dressers; and we state with the same confidence that there is a lamentable want of practical knowledge displayed by candidates at many of our Medical and Surgical examining boards.

The best mode of remedying this condition of things may be matter for discussion hereafter; in the meantime, we do not believe that any good would accrue, as some have supposed, from relaxing the stringency of existing regulations, or entrusting the examination of students to their own teachers.

SUMMARY OF THE WEEK.

MR. GLADSTONE ON LIFE ASSURANCE.

In the course of a very masterly speech on the Government Annuities' Bill, the object of which is to extend the principle of life assurance to the lower classes of society, Mr. Gladstone made same statements in relation to the Medical Profession and to the Medical questions involved in life assurance, which cannot be allowed to pass without comment. In reference to the difficulties which would probably be experienced in obtaining Medical opinions upon the eligibility of lives, Mr. Gladstone is represented as saying that, so far as the lower classes are concerned, Medical opinions are of very little importance, although in the higher classes of life the question of eligibility for assurance is one requiring very great Medical skill and acuteness. We are quite unable to follow Mr. Gladstone's reasoning on this point, and we altogether doubt his assumption that the value of life is so different in the different classes of society. The peer and the peasant are formed of the same anatomical materials, and it requires the same Medical sagacity to discover the existence of latent disease in the one as in the other. But Mr. Gladstone quotes the opinion of "an eminent Medical man" who is the officer of two assurance offices (of course of the provident class), and who is represented as stating that, in the case of industrial assurances, he considered Medical opinions as of no importance. We have some curiosity to know who this eminent Medical man is, and although we have looked through the official lists of several of the provident offices, we cannot find anyone answering to Mr. Gladstone's description. We are obliged to conclude that Mr. Gladstone has been misled as to the degree of confidence he ought to place on the views of his informant, or that the latter has been misunderstood by the Right Honourable Gentleman. Perhaps the depreciation of the value of Medical opinions in the cases referred to may be prospectively designed to avoid payment for any Medical services which may be hereafter demanded under the provisions of the proposed Government measure, and the intimation that the Poor-law Medical officers will probably be required, *as officers of the State*, to afford the necessary information, will, we hope, not be lost upon our Professional brethren. In making these remarks, and in disagreeing with the Medical opinions announced by Mr. Gladstone, we do not object to the principles of his measure, which we believe to be a good one.

PROPOSED LEGISLATION ON THE SOCIAL EVIL.

We understand that it is in contemplation to introduce into the legislature, a Bill having for its object the mitigation of the enormous physical evils which result from prostitution. It is gratifying to find that the subject has attracted attention, and that a desire is manifested in influential quarters to look the matter in the face, and to propose remedial measures. The problem to be solved is to prevent the spread of disease, but at the same time to guard against any undue or vexatious interference with personal liberty. We believe that the infliction of punishment, or at any rate of compulsory segregation for remedial purposes, is one of the features of the proposed measure as applicable to those who wilfully and knowingly become the sources of contagion, but we hope in all fairness that both sexes may be equally amenable to any penalties which may be inflicted for this offence. It must be remembered that in the delinquencies in question, there are always two parties who are equally in the wrong, and it would be cruel

indeed to punish or coerce one, and that the weaker, and allow the other, who is equally guilty, to escape free. The whole subject is, as we have previously remarked, a difficult, a delicate, and an unsavoury one, but from the high character of those who are philanthropically studying the question with a view to legislation, we entertain a reasonable hope that their efforts at meeting the acknowledged obstacles in the way of improvement, will not be made in vain.

THE LINGEN TESTIMONIAL.

The committee appointed to conduct the proceedings, in connexion with the late case in which Dr. Lingen was concerned, have wound up their affairs, and have published a statement, containing a financial account, the minutes of the meetings of the committee, and a list of subscribers. It appears that the subscriptions amounted to 439*l.* 4s., out of which 286*l.* were paid for legal charges, 50*l.* for postage, printing and advertising, thus leaving a balance of 103*l.*, which has been expended in the purchase of some plate for Dr. Lingen, and of a book containing the names of the subscribers. In a graceful letter, addressed to the chairman of the committee, Dr. Lingen has expressed his gratitude for the kindness and sympathy which he has received at the hands of the profession, and of his friends in general.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCEITY.

TUESDAY, FEBRUARY 2.

Mr. PRESCOTT HEWETT, President.

Mr. WALTER COULSON exhibited

THE FRAGMENTS OF THE SHELL OF A MEDIAN-SIZED URIC ACID CALCULUS SPONTANEOUSLY DETACHED AND PASSED THROUGH THE URETHRA.

The patient, a man from Derby, aged sixty-one, was first seen May 26, 1883. He had suffered from bladder irritation for the last five years. Seven months ago a small portion of the shell of a stone came away, and after an interval of a week another bit. He continued to void pieces with his urine for five or six weeks, by the end of which time the shell of a fair-sized calculus had been passed. During this period the urine was deeply tinged with blood, and he suffered acutely. Subsequently, lithotrity was performed, and he was cured after five operations, and it was found that there were two calculi in the bladder.

Mr. WALTER COULSON next showed

ELEVEN STONES REMOVED BY LITHOTOMY.

In this case lithotrity was, in the first instance, attempted, but the cutting operation was resorted to, as the patient was unable to empty his bladder except by the aid of a catheter, in consequence of the quantity of stone contained in the bladder. The patient, aged sixty-five, made a good recovery.

Mr. WALTER COULSON also brought forward

THE SACCULATED BLADDER AND KIDNEYS OF A PATIENT ON WHOM LITHOTOMY HAD BEEN PERFORMED, ALSO TWO CALCULI REMOVED, ONE OF WHICH HAD BEEN ENCYSTED.

The patient had suffered for some years with symptoms of stone. He had been frequently sounded, but nothing had been detected. Mr. Coulson examined him with a lithotrite, and found a stone fixed on the left side of the floor of the bladder, that he was unabled to seize. Lithotomy was resorted to, and the patient died three days after from uræmia. The bladder was sacculated, and contained one large sacculus on the left side of the floor of the bladder, that had evidently lodged one of the stones removed, as at the time of the post-mortem there were still portions of calcareous matter adhering to it. The ureters were both dilated. The left kidney was reduced to a mere cyst, and the kidney structure of the right was much injured. The encysted stone was removed entire, the second in fragments. Both calculi were chiefly phosphatic.

The PRESIDENT said that he had seen the patient from whom the last specimens were taken some years before, and had detected no stone. He then told the patient, however, that he had alkaline urine, and was liable to suffer from calculus. The President also mentioned that he had succeeded in detecting a stone by a catheter, which allowed the urine to escape gradually, when he could not by the ordinary sound. He considered that this was an important point, and gave several instances in which the catheter detected a stone when the sound did not.

Mr. CHRISTOPHER HEATH exhibited

A LARGE MASS OF CALCULOUS MATTER EXTRACTED BY MEDIAN LITHOTOMY IN A CASE OF RETENTION OF URINE.

A man, aged thirty-four, was admitted into the Westminster Hospital with severe traumatic stricture, the result of injury to the perinæum twelve years previously since which time no instrument had been passed into the bladder. A few days after admission retention of urine supervened upon an attempt to pass a catheter, and it became necessary to afford relief. The point of the catheter touching calculous matter in the prostate, and being thereby prevented from reaching the bladder. The patient was tied up in the lithotomy position, and Mr. Heath made an incision in the median line to extract the calculi. It was found, however, that in addition to the prostatic calculi, there was a large vesical calculus, which prrved to be adherent to the left side of the bladder. After one or two attempts at removal, the stone broke in the forceps, and was extracted piecemeal. A large number of prostatic calculi were removed, and there was then found to be a quantity of calculous matter adherent to the coats of the bladder in various parts. This was scraped away with the scoop as far as possible, and removed. The patient did well, and made a perfect recovery, the stricture being subsequently treated by Holt's dilator. The calculi exhibited consisted of two distinct formations, vesical and prostatic, the whole mass weighing 1,084 grains (or 18 drachms, 4 grains), and the small prostatic calculi alone 46½ grains. The prostatic calculi averaged the size of barleycorns, and were of a dark brown colour. The portions of vesical stone were found to form two distinct calculi, one composed of fusible calculus around a nucleus of phosphate of lime deeply coloured with animal matter, the pieces of which weighed 832 grains, and which had evidently been adherent to the coats of the bladder; and the other, of very remarkable shape, and weighing 104 grains, which consisted of a nucleus of phosphate of lime deeply coloured, very smooth, and of the size and shape of a sparrow's egg (39 grains), with a surrounding portion of phosphatic matter, more resembling a gigantic "os unciforme" than anything else. These latter pieces came away in the forceps in the middle of the operation, but their source was doubtful. The *débris* of phosphatic matter removed from the bladder weighed 101½ grains.

Mr. HEATH also exhibited

A SPHERICAL CALCULUS REMOVED FROM THE BLADDER AFTER DEATH.

This calculus was removed post-mortem by Mr. Bullen, of the Lambeth Workhouse, from the bladder of a man aged eighty-two, who had had hardly any symptoms of urinary affection during life. The calculus was remarkable for its nearly perfect spherical shape.

Dr. MURCHISON showed a specimen of

CANCER OF THE ŒSOPHAGUS COEXISTING WITH RECENT TUBERCLE IN THE LUNGS.

A man, fifty-four years of age, who was, until the illness of which he died, very healthy, although very intemperate, began to get thinner, to swallow with difficulty, and to vomit immediately after his meals. He died at the end of ten weeks. It was found at the autopsy that there was

stricture of the œsophagus, an inch and a-half above the cardiac orifice of the stomach. The mucous membrane was free from ulceration, but was puckered, and there was a little fistula leading into the tumour from the œsophagus. The tumour, which was in the posterior wall was dense and translucent. The glands in the neighbourhood were healthy. The lungs were found to contain, at their apices, old and recent tubercles, calcareous nodules, and cheesy matter, and scattered miliary tubercle. He had thought at first that the tumour might also have been tuberculous, but it contained abundance of characteristic cancer cells.

In reply to Mr. Sidney Jones, Dr. Murchison said that the tubercle in the lungs had been examined microscopically.

Mr. W. ADAMS exhibited

TWO LEGS OF A CHILD WHO HAD BEEN THE SUBJECT OF CONGENITAL TALIPES VARUS.

The child, aged eleven months, had died of acute inflammation of the lungs. Both legs, as now exhibited, were free from deformity, the Achilles and the anterior and posterior tibial tendons having been divided five months before death. In each of the Achilles tendons there was half an inch of new tendinous tissue inserted between the divided extremities of the old tendon, which was thus elongated. Externally, the tendon was well defined, and its surface even throughout, so that there were no traces of the operation, but the new tissue was easily distinguished on the recent section by its grey translucency, contrasting with the opaque pearly lustre of the old tendon. Both the posterior tibial tendons had united, but in one of them the free play of the tendon was limited by adhesions, whilst in the other only very slight adhesions existed. Mr. Adams remarked that he had already published fifteen post-mortem examinations after tenotomy, and, since the publication of his work on this subject, had made at least five or six more which confirmed the opinions he already advanced. With regard to the posterior tibial tendon, Mr. Adams observed that he employed gradual extension for a week before the operation, to limit the separation of the cut extremities, and thus favour union.

Mr. BARWELL said that he had never denied that the posterior tibial tendons would unite, but had said that they contracted adhesions. He had never operated in such cases, and had never found it impossible to replace the foot.

Dr. CAMPS suggested that the deformity might be due to paralysis rather than to contraction.

Mr. W. ADAMS said that in cases of congenital varus, such as the present, there was not a shadow of evidence that paralysis ever existed. He had never seen such a case, though in some rare instances congenital deficiency of some of the muscles of the leg existed, and at first this condition might be mistaken for paralysis. Non-congenital paralytic deformities were common enough, and in some of these cases the most brilliant results in Orthopædic Surgery were obtained by tenotomy.

Mr. MAUNDER remarked that in cases of wounds, on healing, tendons would be glued to the skin in the cicatrix, but after a time they became loose again.

Mr. BARWELL said that there was a difference in the wounded limb of a strong healthy man and a weak child's leg on a splint.

Mr. POLLOCK showed a specimen of

RUPTURE OF FATTY HEART.

A lady, sixty years of age, very fat, was seized with acute pain, and died suddenly. A rent was found in the anterior part of the left ventricle, and the pericardium was distended with blood. The other viscera were healthy.

Mr. POLLOCK showed a specimen of

NECROSIS OF THE THYROID CARTILAGE.

The patient had been admitted, October 7, for extreme difficulty of respiration and husky voice and cough. A few days later laryngotomy was performed, with immediate relief. On the fifth day the patient was better, the tube was withdrawn, and finally the orifice healed. The laryngoscope showed that on one side the glottic orifice was contracted, and on the other there was swelling. The patient died suddenly one night, having had but very slight previous dyspnœa. The aryteno-epyglotidean folds were thickened, and a piece of the thyroid cartilage, necrosed, was found in an abscess.

Dr. GIBB exhibited a specimen of

STRICTURE OF THE TRACHEA AND GROWTHS OF THE LARYNX,

from a lad of 19, who had been admitted into the Westminster Hospital with extreme dyspnœa, which was at first supposed to depend upon laryngeal obstruction. On the tenth day tracheotomy was performed by Mr. Holthouse, but a tube could not be worn, in consequence of the existence of constriction of the trachea, this condition being found after death to have involved the entire tube, as well as both large bronchi, thus rendering the cause of the dyspnœa threefold—namely, obstruction of the larynx, trachea, and bronchi. The patient had suffered from former attacks of laryngitis coincident with glanders.

Mr. SYDNEY JONES showed a

SKULL CONTAINING A TABLE-KNIFE.

It had been driven through the orbit into the cranial cavity, the point projecting through the bone behind.

Mr. SYDNEY JONES also showed a skeleton of a foot, in which there were two internal cuneiform bones.

Mr. HINTON presented, for Mr. Toynbee, the

LEFT PETROUS BONE AND SOME PORTIONS OF DURA MATER, FROM A PATIENT WHO DIED WITH CEREBRAL SYMPTOMS.

The specimen had been sent him by Mr. Lacy, Surgeon to H.M.S. *Cumberland*. The patient had been under treatment a year ago for suppurating bubo, but had recovered. Fourteen days before his death he was placed on the sick-list for coryza and discharge from the ear. About a month before he had had acute pain in the ear, but none lately. The face shortly became paralysed on the left side. He sank gradually, with scarcely any complaint of pain. A day or two before his death a profuse gush of purulent matter escaped from the ear. On removing the calvaria, a number of firm growths were observed, firmly attached to the dura mater in various places, and varying in size from a pin's head to a hazel-nut. The vessels of the pia mater were full of blood, but there was no effusion or softening. The larger growths had made marked impressions on the adjoining convolutions, the largest indentation being on the left lobe of the cerebellum. Otherwise, the membranes and brain substance were healthy. The left membrana tympani was destroyed, and the root of the tympanum had a slightly-darkened and worm-eaten appearance. The tympanic cavity was full of pus. The head only was examined, but there existed no symptom indicating disorder of any other organ than the brain.

HARVEIAN SOCIETY.

FEBRUARY 18, 1864.

WM. ADAMS ESQ., PRESIDENT, in the Chair.

DR. TILBURY FOX brought before the Society a child affected at once with herpes circinatus and favus. Numerous patches of h. circinatus covered the body, and under one axilla there was a patch of favus, portions of which under the microscope showed the cells of achorion schönleinii. Dr. Fox thought that these cells might be developed from those of h. circinatus.

MR. SQUIRE said that no doubt the cells befere them were those of the achorion ; but it did not follow that this was anything but coincidence.

DR. CAMPS said that the patch of favus did not appear to be implanted on any of the patches of herpes c.

DR. DRYSDALE asked whether Dr. Fox had ascertained whether there were any cases of favus capitis in the same house or family, as this complaint was easily inoculable.

Dr. FOX replied in the negative.

A paper was read by CUNDELL JULER M.D., entitled

AN INQUIRY INTO NERVOUS REFLEX ACTION AS A CAUSE OF DISEASES OF THE SKIN, WITH REMARKS ON THEIR TREATMENT.

The author commenced his discourse by showing that the opinion generally received of morbific blood, being the *fons et origo* of diseases of the skin was erroneous ; that the past labours of the pathologist, the histologist, and the chemist, did not warrant our arriving at such an assumption. He quoted from the works of various authors to show how many affections of the skin as zona, erythema, pemphigus, urticaria, elephantiasis græcorum, leprosy, &c., had been traced to a nervous influence. He instanced many cases as being clearly referrible to a morbid reflex influence on the nutrition of the sensitive nerve fibres, passing to the cerebro-spinal axis, either from the skin or from the intestinal mucous membrane. He considered derangement of innervation as necessarily preliminary to the appearance of parasitic diseases ; the different conditions of the skin in various places, accounting for the appearance of two or more varieties of parasites, upon the same individual. Dr. Cundell Juler stated it to be his opinion, that specific forms of disease of the skin were induced by the morbific element in the blood acting upon the nervous centres primarily and secondarily through the centrifugal nerves, upon the cuticular surface. He stated his conviction that all skin diseases had their origin in some disorder of the nervous system, and that many were attributable to nervous reflex action. He mentioned alternations of temperature as being a fruitful source of skin disease, heat and cold being most powerful irritants to the nerves of the skin. He instanced furunculi, urticaria, lichen, erysipelas, &c., as being rapidly developed in this manner. Dr. Cundell Juler then passed on to say that he thought that upon the recession of a chronic cuticular eruption, the internal lining membrane of the bowels, sometimes became the seat of a disease similar in its pathological character to skin eruptions, inducing the discharge of shreddy adherent mucus from the bowels, probably depending upon a rapid shedding of the epithelium of the mucous membrane. The re-appearance of the disease upon the skin, he said, restored the bowels to their former healthy condition ; the internal and external affections being vicarious of each other. He next demonstrated how skin diseases might assume a chronic character by a morbid alteration in the blood-vessels and tissues of the skin, and thus remain after the nervous irritation which had brought them into activity had subsided. In this condition these diseases only needed external remedies for their removal. After showing how irritants to the afferent nerves of the skin might produce eruptions and abnormal states or ulceration of the skin or lining mucous membrane of the body as in burns, he referred to many cases to prove the converse as being also the case, by the action of irritants upon the centripetal nerves of the bowels, &c., causing pain and diseases of the external surfaces of the body or intestinal surfaces. He instanced many cases to show how skin affections were attributable to the irritation of nerves of the intestinal mucous membrane by indigestible ingesta, &c. He explained how irritation of afferent nerves might not always induce skin eruptions, but give rise to other nervous phenomena. He quoted Brown-Séquard to show how insanity, epilepsy, chorea, catalepsy, extasis, hydrophobia, hysteria, and other varieties of nervous complaints might arise from some slight irritation of centripetal nerves, and explained how irritation of the dental nerves, or of the bowels in infants, gave rise at one time to skin eruptions, at others, to a discharge of a shreddy mucus from the bowels. In discussing the treatment, Dr. Cundell Juler attributed the curative influence of arsenic over skin diseases as being due to its power of establishing a counter action in the system, and so exhausting the undue irritability of the nervous system, so long as it had a morbid condition with which to contend ; its action was strengthening and curative, but as soon as the disease was removed, or the system became more saturated with the remedy than with the disease, it was no longer strengthening, but set up an irritation similar to the one it had removed, producing similar cuticular manifestations, and all the nervous phenomena of a poison acting upon the nervous centres. After advocating electro-galvanism in some forms of skin diseases clearly referrible to nervous reflex action, and having said a few words as to general treatment, he concluded by recording cases illustrative of his theory and the treatment founded thereupon.

Dr. FULLER thought that all would agree with the author of the paper, that we must not look upon arsenic as a sheet-anchor in skin diseases, as there were many cases in which it did more harm than good. Diet is of the utmost importance in skin diseases, and stimulants and generous diet often effect a cure, in eczema especially; arsenic sometimes aggravates instead of curing. Tartarised antimony is sometimes useful. He could not agree that changes of temperature frequently caused skin disease, as persons who took Turkish baths would in that case be very liable to them. Indigestible substances frequently caused skin disease, and probably because some poison was absorbed into the blood.

Dr. T. FOX remarked that practitioners usually treat psoriasis by internal means only ; but Hebra uses stimulating applications, such as oil of cade and unguentum sulphuris. Devergie says that he thinks that psoriasis is rather injured than benefited by arsenic.

Mr. SQUIRE thought that first attacks of psoriasis and eczema were more curable by arsenic than after-attacks. Donovan's solution, containing arsenic, mercury, and iodine, was very useful.

Mr. ERNEST HART mentioned that boils often arise in persons who indulge in Turkish baths, and that in Séquard's experiments on epilepsy, the spot, which on being irritated produced fits, was covered with lice.

Dr. HARE had given arsenic as long as twelve months without evil effects, but much good. We should also use external applications, and we should not trust to one remedy in psoriasis. Acetate of potash was often useful, and tar ointment locally ; in cloasma, local applications are all that is required, as ung. hyd. nit. ox., and so with regard to tinea tonsurans.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 1ST, 1864.

MR. PARTRIDGE, PRESIDENT.

ANNUAL MEETING.

At the commencement of the meeting, the President declared the ballot open for the election of the Officers and Council for the ensuing year, and nominated Dr. Kirkes and Mr. C. H. Moore as scrutineers.

The Reports of the Treasurers and of the President and Council were then read in succession. From the former, it appeared that the Society was in an increasingly prosperous condition. The total ordinary income of the year had been 1,352*l.* 12s. 9d., which, with the amount of composition fees, 43*l.* 1s., and a balance from the previous year's account of 357*l.* 19s. 9d., gave a total of 1,753*l.* 13s. 6d. ; and against this sum the ordinary expenditure, inclusive of 181*l.* 14s. 6d. on the library, and 202*l.* 16s. 3d. on the 'Transactions,' &c., was 985*l.* 5s. ; the extraordinary expenditure (for alteration in the meeting-room, &c.) 34*l.* 7s. 7d., and the sum of 500*l.* 13s. 9d. purchased into the funds ; leaving a balance of 233*l.* 7s. 2d. in the treasurers' hands. It will thus be seen that the total receipts of the Society for the last two years had exceeded its expenditure by about 700*l.*

Mr. ARNOTT moved, and Dr. WEBSTER seconded, the adoption of the report.

Dr. WEBSTER said that, from the statement just exhibited, it appeared that the Society's rent amounted to 1*l.* 2s. 10d. only.

The Report of the President and Council stated that the total number of Fellows was 634—a slightly smaller number than in the previous report ; but this was accounted for principally by the large number of deaths (16) which had

occurred amongst the Fellows. The report referred in detail to the steps which had been taken by the Council since the last general meeting relative to the ventilation of the meeting-room, its appointment of a committee on the subject, and their recommendations. A portion of these only, owing to insufficiency of time during the ordinary closure of the library in the autumn, had been carried out, consisting of a window over the entrance door of the room, and an apparatus for opening a portion of the skylight, by which it was believed a great improvement in the ventilation of the room had been effected at a small cost. The report also stated that 323 new works, exclusive of periodical publications, had been added to the library; and also referred to the munificent donation of Mr. Soden, of Bath, of the collection of Medical portraits formed by his late father, Mr. John Smith Soden. Other portraits had since been presented by the Fellows of the Society; and in consequence of a letter from Mr. Propert, as executor of the late Mr. Squibb, and on the recommendation of the Library Committee, the Council had resolved to offer 70*l.* for Mr. Squibb's well-known collection—subject to the confirmation of the annual meeting. If purchased, the Society would possess a collection of considerably above 2,000 engraved Medical portraits, some of which were of great rarity and value. The report also referred to the photographic collection of portraits of Fellows of the Society in continuation of the above, and the collection of pathological photographs, further contributions to which were much desired by the Council. The committee appointed by the Council, "On the Uses and Effects of Chloroform," were unable to conclude their labours last year; but their report would now shortly be presented to the Society, and would be published in the next volume of the 'Transactions.'

Mr. CÆSAR HAWKINS moved, and Dr. BARKER seconded, the adoption of the report.

Dr. GREENHOW remarked on the great improvement in the ventilation of the room. It had been the worst ventilated room he had known, but now it was perfectly comfortable and healthful.

Mr. CHARLES HAWKINS thought it would not be advisable to alter the lantern; it would be throwing money away. He hoped the balance would be taken care of, and not be frittered away.

Dr. WEBSTER said that having taken much interest in the subject of ventilation of the room, he would remark that he quite agreed that it would not be necessary to spend more money on it, as the result already obtained was very good. He thought that as the Society was a royal Society, there ought to be either a portrait or a bust of Her Majesty in the room. It would almost seem that the architect had made the recess behind the President's chair for such a purpose. In all foreign societies it was usual to have a bust of the sovereign, and he suggested that the Royal Medical and Chirurgical Society ought to have one of the Queen.

Mr. SPENCER WELLS asked if the Council intended to continue the high charges for the use of the room to the Pathological Society. Strong remarks had been made at the meeting of the latter Society on this point, and as a member of the Royal Medical and Chirurgical Society, he felt ashamed of the extortionate charge. It did not seem fair that this Society should stand rent free by making a high charge to a sister Society. He hoped the Council would act in a more liberal spirit in this matter.

The PRESIDENT said that to double the rent of the two sister Societies (the Pathological and Obstetrical) was not so inconsistent as might appear at a first glance. It ought to be remembered that the Pathological Society was received at first at a mere peppercorn rent, as the funds of that Society were low, and it was well known that the rent was not commensurate with the advantages. Then, again, he question had been unfairly stated. It was not fair to assert that the rent was at the rate of four guineas an hour, as if the hours were consecutive. It was just the difference in engaging the Freemason's Tavern on thirty occasions for an hour or for thirty hours in succession. Then the proof that the rent was not too high was this, that the Pathological Society could not obtain rooms at so low a rate in any other part of London. However, he would rather the rent were less than that difficulties should arise betwixt the Societies.

Dr. C. J. B. WILLIAMS was glad to hear the President's last remark. It seemed to him (Dr. Williams) that the very fact that the Medico-Chirurgical Society was living rent free was evidence that it mulcts its tenants to a good rate. It was unfair to put pressure on the Pathological Society. The rent at first was moderate, but to double it at once was preposterous. It was now a question whether the Pathological Society could meet the charge consistently with publishing their 'Transactions.' Sixty guineas a year was more than the Pathological Society cost the Medical and Chirurgical Society.

Mr. CHARLES HAWKINS thought that the discussion ought to have taken place before the money vote. The words used, "extortionate" and "extraordinary," were, he thought, misapplied. If the Pathological Society were so important and so flourishing as Mr. Spencer Wells had said, it was strange that it could not pay sixty guineas a year. If that Society could get rooms at such a rate elsewhere, they might do so. They had not only the rooms, but gas, and the services of the librarian and other officers. It spoke poorly for the Society to apply *in formâ pauperis*. If it were worth supporting it would be supported, but not at the expense of the Medical and Chirurgical Society. They had the *prestige* of being associated with this Society, and he did not see why they should receive anything in the way of pecuniary assistance. If Mr. Wells wished for an expression of the opinion of the Society, he ought to bring forward a distinct resolution.

Mr. ARNOTT said that besides the use of the rooms, the Pathological Society received, in the way of warming, lighting, &c., considerable advantages. He did not think the rent at all extortionate.

Dr. BARCLAY said that the item (169*l.*) for wages to the Society's servants had been overlooked, although the Pathological Society had the services of their paid officers. It was felt at the time when the first arrangement was made, that it was a peppercorn rent, and that they were scarcely acting fairly to themselves. When all the advantages were considered, he thought it would be admitted that sixty guineas was a low rent.

Dr. BARKER said it was a mistake to suppose that they lived rent free.

The PRESIDENT then commenced his Address, the publication of which is postponed until next week.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

MARCH 9.

WEIGHTS AND MEASURES (METRIC SYSTEM) BILL.

Mr. W. EWART moved the second reading of this bill. He referred to his speech when introducing the bill of last year, and to what had occurred since, in commendation of its object. The present bill, however, was permissive, instead of being compulsory, and he read testimonials of trades to the probable success of a permissive measure.

The motion was seconded by Mr. Locke, who suggested that there ought to be an assimilation of our coinage to our weights and measures, there being at present no analogy between them.

Mr. M. GIBSON observed that the views of Mr. Locke as to the advantages of a decimal system of coinage and weights and measures had nothing to do with the Bill, which proposed to change the unit. At present we had two standards —the yard and the avoirdupois pound, and if this Bill passed there would be a third—namely, the metre, the ten-millionth part of an arc from the Equator to the Pole. He thought the evils complained of in the present system in regard to our foreign trade might be easily remedied. Last year he had objected to a compulsory measure; not objecting to the principle of permission, he did not oppose the

second reading of the Bill, but he could not consent to some of the clauses as they now stood.

Mr. HENLEY observed that the Bill would set up rival modes of buying and selling, and open a door to frauds upon the poor.

Mr. WALTER said the measure ought to be made compulsory. Permissive legislation on such a subject was out of the question. He objected, however, to this measure, which he thought revolutionary and needless. It introduced a foreign nomenclature, which would be most distasteful to the public, and subverted our existing standard of weights and measures, without any sufficient cause being shown for their destruction. He moved to defer the second reading for six months.

Upon a division, the amendment was negatived by 90 to 52, and the Bill was read a second time.

CATTLE DISEASES PREVENTION BILL

Mr. H. A. BRUCE, in moving the second reading of this Bill, showed the extent of the evil which the measure proposed to remedy, and the enormous loss resulting from cattle disease, and explained what had hitherto been done to deal with the evil by providing against the importation of diseased cattle. He then stated the provisions of the Bill, which consolidated and extended the existing law. He proposed that the Bill should be referred to a Select Committee.

After a short discussion, the Bill was, with the Cattle, &c., Importation Bill, read a second time, and both were ordered to be referred to a Select Committee.

LEGAL INTELLIGENCE.

CHARGE OF MANSLAUGHTER AGAINST A HERB DOCTOR.

The following are the particulars of a case tried at Durham before Mr. Justice Willes on March 2. The verdict seems to have been clearly contrary to the evidence and to the judge's direction.

The prisoner, a man named Joseph Levy Markuss, kept a shop in Sunderland, where he passed as a herb doctor, or "herbalist." Being acquainted with the deceased, Jane Sumby, who also kept a shop in Sunderland, he chanced to call on her on Sunday, the 6th of September last, and found her labouring under the effects of a cold from standing in the market. She complained to him of pains in her back, and appeared to have been ailing for some days. The prisoner volunteered to prescribe for her, and sent her daughter for 6d. worth of pale brandy in a 6oz. bottle. Into this he put about an ounce of meadow saffron seeds, known medically as colchicum seeds, first bruising them, and directing the deceased's daughter to place the bottle before the fire for two hours, and then shake it up and give her mother a tablespoonful. The daughter did as directed, giving her mother a tablespoonful about 2 o'clock on Monday, the 7th. The deceased became ill and sick shortly after, and, after taking some tea at 4 o'clock, vomited violently, and continued, at short intervals, vomiting and retching till she died exhausted at 10 o'clock on Wednesday morning. Dr. Nattrass was called in on Monday night, and prescribed for her two opium pills of a grain each, and next day gave her small doses of prussic acid and soda to allay irritation, and directed her to have soda water and milk, weak brandy and water, and lemon juice and water to allay her thirst, and arrowroot and weak brandy and milk as sustenance, but her stomach was so irritable it would retain nothing, and on Tuesday he ordered her an injection to sustain vitality. While attended by her daughter and neighbours, it appeared that she had several times taken small quantities of brandy neat to try and stop her sickness, and had also taken some "nerve powder," which a neighbour recommended. This powder, when analysed, was found to consist of valerian, skunk-cabbage, gentian, ginger, and some other ingredients, harmless in themselves, and which would act as a stomachic in ordinary cases. A post-mortem examination was directed by the coroner, and the deceased's internal organs were found to be healthy, with the exception of the heart, which showed slight symptoms of fatty degeneration, and the stomach, the internal coat of which was of a violet colour from intense inflammation. She had died from gastritis, or inflammation of the stomach, which the Medical men who attended her attributed to the overdose of colchicum seeds she had taken by direction of the prisoner. The bottle in which was this mixture was delivered up for analysis to Mr. Pattenson, the analytical chemist, of Newcastle, who found it to be brandy and colchicum seeds. Two grains of colchicum seeds, in the form of tincture, was a dose. A teaspoonful of the mixture would contain 18 grains, and was a fatal dose, and a tablespoonful contained 80 grains. This was a highly poisonous and fatal dose, the drug being a narcotic irritant poison. In the judgment of the Medical men this was the cause of death. The counsel for the prosecution, in his opening, drew attention to the law, which made no distinction between regular practitioners and quacks, both being responsible for culpable and gross negligence, and liable to be indicted for manslaughter if by culpable and gross ignorance or negligence they were the cause of the death of a patient, and submitted that it was some evidence of culpable negligence if a man, being an irregular practitioner, and ignorant of the qualities of a dangerous drug, yet undertook to prescribe it in quantities dangerous to life, and if such an act led to fatal results he was amenable to the charge of manslaughter.

The defence urged was that when analysed the infusion, or tincture of colchicum, had become much stronger than when administered to the deceased, and that it was the continued doses of brandy, and the nerve powder, acting on a stomach attacked by gastritis from cold, which had increased the disease by increasing the inflammation, and had thus caused death.

His Lordship, having summed up the evidence, directed the jury as to the law. Every person who dealt with the health of others was dealing with their lives, and every person who so dealt was bound to use reasonable care, and not to be grossly negligent. Gross negligence might be of two kinds, and in one sense,—where a man, for instance, went hunting and neglected his patient, who died in consequence. Another sort of gross negligence consisted in rashness, where a person was not sufficiently skilled in dealing with dangerous medicines, which should be carefully used, of the properties of which he was ignorant, or how to administer a proper dose. A person who with ignorant rashness, and without skill in his profession, used such a dangerous medicine acted with gross negligence. It was not, however, every slip that a man might make that rendered him liable to a criminal investigation. It must be a substantial thing. If a man knew that he was using medicines beyond his knowledge, and was meddling with things above his reach, that was culpable rashness. Negligence might consist in using medicines in the use of which care was required, and of the properties of which the person using it was ignorant. A person who so took a leap in the dark in the administration of medicines was guilty of gross negligence. If a man was wounded and another applied to his wound sulphuric acid or something which was of a dangerous nature and ought not to be applied, and which led to fatal results, then the person who applied this remedy would be answerable, and not the person who inflicted the wound, because a new cause had supervened. But if the person who dressed the wound applied a proper remedy, then, if a fatal result ensued, he who inflicted the wound remained liable.

The jury retired to consider their verdict, and after being absent for some time, returned with a verdict of "Not Guilty."

HOWISON.—On the 13th ult., at Northgate House, Darlington, the wife of Dr. Howison, of a daughter.

WATSON—HOLDER.—On the 10th inst., at St. Barnabas, Kensington, by the Rev. Dr. Hessey, assisted by the Rev. J. McCaul, Charles George Watson, Esq., late Surgeon R.N., to Amy, only child of the late W. J. Holder, Esq., of Kensington.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 3rd inst.:—Edward Sidney Lloyd, Pill, near Bristol; John Powdrell, Farndon, near Chester.

ROYAL COLLEGE OF SURGEONS.—At a special meeting of the Court of Examiners on the third instant, Mr. James Alexander Grant, of Ottawa, Canada West, having undergone the necessary examination, was admitted a member of the College. This gentleman had previously been admitted a Doctor in Medicine of McGill College, Montreal, his diploma bearing date May 4, 1854.

ROYAL INSTITUTION OF GREAT BRITAIN.—General monthly meeting. Monday, March 7, 1864. William Pole, Esq. M.A., F.R.S., Treasurer and Vice-President, in the chair. Joseph Henry Anderson, Esq.; Henry Cook, Esq.; Baldwin Francis Duppa, Esq., J.P.; Thomas Hankey, Esq.; William Helps, M.D.; Arthur James, Esq.; Sir Edwin Landseer, R.A.; Hananel De Leon, M.D.; John J. Lowndes, Esq.; Colin Macrae, Esq.; John Rae, Esq.; Lieut.-Colonel Joseph Carleton Salkeld; William Spottiswoode, Esq., F.R.S.; Herman Stern, Esq.; Thomas Stevenson, M.B.; Joshua Williams, Esq.; Mrs. Emily Yorke, were *elected* Members of the Royal Institution. Jackson Hunt, Esq.; David S. Price, Esq.; and John Rae, Esq., were *admitted* Members of the Royal Institution. The presents received since the last meeting were laid on the table, and the thanks of the Members returned for the same.

POOR-LAW MEDICAL REFORM ASSOCIATION.—Mr. Griffin begs to announce that within the last few days he has received the following subscriptions in aid of the funds of the Association:—H. Horton, West Bromwich, 5s.; R. B. Reid, West Derby, 1*l.*; J. L. Gardine, Dorking, 10s.; W. T. Gaye, Williton, 10s.; A. F. Brett, Watford, 10s.; W. A. Hubert, Hemel Hempstead, 10s.; C. H. Perry, Aylsham, 10s.; W. S. Black, Freebridge Lynn, 10s.; J. Brewer, Newport, 1*l.*; G. M. Phillips, Hitchin, 7s. 6d.; J. Hair, Sudbury, 2s. 6d.; J. E. Brine, Shaftesbury, 1*l.* 1s.; W. H. R. Bennett, Shaftesbury, 1*l.* 1s.; E. J. Miles, Shaftesbury, 1*l.* 1s.; R. Griffin, Weymouth, 1*l.* 1s.; W. H. Blenkinsop, Easthampstead, 10s.; H. B. Smith, Ticehurst, 7s. 6d.; J. Clouting, Mitford and Launditch, 10s.

APPOINTMENT.—Balmanno Squire, M.B., F.L.S., has been appointed one of the Lecturers in St. Mary's Hospital Medical School.

CORK FEVER HOSPITAL.—The funds of this institution being exhausted in consequence of the prevalence of the disease, an anonymous "Friend" dropped a letter in the box of the 'Constitution' containing a £100 note for the hospital.

PROPOSED NEW WEIGHTS AND MEASURES.—The weights and measures to be authorised by Mr. Ewart's Bill, if it should pass, will be as follows:—Instead of the yard, there will be the "metre," which will be about a yard and a tenth—39·371 inches, the other measures of length to be its decimal multiples or divisions; thus, on the one hand, there will be ten metres, called the "dekametre," and on the other the tenth of a metre will be the "decimetre," and so on. 1,000 metres, a kilometre, will be the nearest approach to the old mile; it will be nearly two-thirds of a mile—0·621. For square measure the unit will be an "are," which will be about 120 square yards—119·603; a "centiare" the hundredth part of an are or a square metre, will be the nearest to our square yard, being one-fifth more—1·126. 100 ares, a hectare, are 2·471 acres. For measures of capacity the unit will be the "litre," about a pint and three-quarters—1·761. Ten litres, a "dekalitre," will be two gallons and a fifth—2·201. The small drinker may take his "decilitre," about the sixth of a pint (0·176), or his "centilitre," which is the tenth part of a decilitre. For weights the unit will be a "gram," nearly 16 grains—15·433; 1,000 grams, a "kilogram," will be about 2lb. and a fifth of a pound—2·205; 1,000 kilograms, 2,204·714lb. will be a ton. The double and the half of all these measures and weights may also be used.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAR. 16.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.

THURSDAY, MAR. 17.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Marshall, "On Animal Life," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia;" Chemical Society, 8 p.m.—Sir Benjn. Brodie, "On the Theory of Organic Peroxides;" Harveian Society, 8 p.m.—Dr. Camps, "On some Points in the Pathology of Convulsive Diseases."

FRIDAY, MAR. 18.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Professor Tyndall, "Contributions to Molecular Physics."

SATURDAY, MAR. 19.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements;" Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, MAR. 21.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAR. 22.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

A Manual of Diet and Regimen for Physician and Patient. By Dr. H. Dobell. London: John Churchill and Sons.

Excision of the Scapula. By James Syme, F.R.S.E. Edinburgh: Edmonston and Douglas.

The Prescriber's Analysis of the British Pharmacopœia. By J. Birkbeck Nevins, M.D. Lond. London: John Churchill and Sons.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

To SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

Mr. GRIFFIN's communication is inserted.

THE HARVEIAN SOCIETY.—The Report has been received.

THE ROYAL INSTITUTION.—The notice has been received.

THE REPORT OF THE LINGEN TESTIMONIAL has been received.

A WORKING BEE.—The letter is inserted.

NAVIS.—Apply to F. G. Moore, M.R.C.S. Eng., who is the Agent recognised by all the London and Provincial Houses. 14A St. Mary Axe, Leadenhall street, E.C. Hours, 10 to 5.

Dr. C.—The paper has been returned, after perusal, to the proper quarter. The Report will be acceptable.

Dr. J.—We have been informed of the particulars, but we consider that they can have no real interest for our readers.

AN ASSISTANT.—The publication of the absurd advertisements would only give increased currency to the trash, and a personal exposure of the advertiser might, perhaps, render us liable to an action for libel.

WE feel much indebted to many correspondents who have favoured us with their views on the subject of Medical Education, and we shall make use of the information in due time.

THE PHARMACEUTICAL SOCIETY.—The card has been received.

Mr. W. M.—The suggestion shall be taken into consideration.

THE continuation of the article on Army Reports is deferred until next week.

THE OBSTETRICAL SOCIETY.—The Report has been received, but is unavoidably postponed until next week.

Testimonial to Dr. Liveing,

DEMONSTRATOR OF ANATOMY AT THE MIDDLESEX HOSPITAL.

On Thursday last, the 10th inst., this Gentleman was presented with a handsome Silver Cup by the Students of this Hospital, bearing the following inscription:—"Presented to R. LIVEING, Esq., M.A., M.B. Cantab., by the Students of the Middlesex Hospital Medical College, as a slight mark of their appreciation of his uniform kindness and attention to them while pursuing their Anatomical Studies."

Testimonial to Dr. Day.—Subscri-

bers to the testimonial to Dr. Day (late of St. Andrews) whose subscriptions have not yet been sent will greatly oblige by forwarding them to to the undersigned. Particulars respecting the testimonial have been posted to those subscribers who have paid up to the present date.

B. W. RICHARDSON, M.D.
19, Hinde Street, London, W. Hon. Treasurer,
March 12th 1864.

Royal College of Physicians of

LONDON.

FIRST Part of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School, will commence on Tuesday, April 5th.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licencewill commence on Tuesday, April 12th.

Graduates in Medicine of a University recognised by the College, Licentiates of the Royal College of Physicians of Edinburgh, or of the King and Queen's College of Physicians in Ireland, and Registered Medical Practitioners qualified before January, 1864, are admitted to Examination, under special Bye-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials, required by the Bye-laws are to be left at the same time.

H. A. PITMAN, M.D. Registrar, Pallmall East.

Apothecaries' Hall.—The Court

OF EXAMINERS OF THE SOCIETY OF APOTHECARIES, LONDON, hereby give Notice, that, after the close of the present Winter Session, Students will have the option of being examined in the Pharmacopœia Londinensis, or in the British Pharmacopœia.

ALFRED M. RANDALL, Secretary to the
28th Jan., 1864. Court of Examiners.

Apothecaries' Hall.—The next ex-

amination in Arts will be held at the Hall on Friday and Saturday, the 29th and 30th April, 1864. A Syllabus of the Subjects for Examination may be had on application.

An examination will again be held in the month of September 1864.

R B. UPTON, Clerk to the Society.

To Surgeons and General Practi-

tioners. A young gentleman, who has three years' Lectures and Hospital Attendance out, and has lived for two years with a general practitioner in large practices in Dublin, and has there been accustomed to prescribing and compounding, would wish for an engagement as Assistant in London.

Address, HENRY ADAMS, Poste Restante, Post Office, Dublin.

Emperor Life and Fire Assurance

SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

New American Preparations.—

W. TWINBERROW begs to inform the Medical Profession that he has had a large consignment (direct from Keith & Co., of New York) of ALL the MOST VALUABLE American Medicinal Preparations. Also—

EXT. CANAB. INDICA, direct from Calcutta.
PIERLLCT'S VALERIANATE of AMMONIA.
Mauufacturer of the New Preparation of
PEPSINE with Wine—PEPSINA PORCI—Ditto VITULI.
PHARMACEUTICAL CHEMIST.
Edwards Street, Portman Square, and 59B Westbourne Grove, London.

Liquor Folii Ricini or Fluid Extract

of the Palma Christi Plant, for increasing the Secretion of Milk in Suckling women.

Mr. GREENISH solicits the attention of the Profession to the above preparation, which is now in great demand.

Dose: One teaspoonful three times a day.

Prepared by THOMAS GREENISH, Chemist, 20 New st., Dorset-sq.

Coxeter's Illustrated Catalogue,

much enlarged, price 1s. 6d., including postage.

Mr. Henry Thompson's Dilator

for Gradual Distension of Stricture.

COXETER, 23 & 24 Grafton street East, London, W.C.

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible or have altogether failed in effect. Imitations having arisen, be particular in the address.

Hedges & Butler, Wine Merchants,

&c., recommend and GUARANTEE the following WINES:

Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s.	and	30s.	per dozen.
Good Hock	30s.	,,	36s.	,,
Sparkling Epernay Champagne, 36s.,	42s.	,,	48s.	,,
Good Dinner Sherry	24s.	,,	30s.	,,
Port 24s.,	30s.	,,	36s.	,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820 at	120s	per dozen.	
Vintage 1834	,, 108s.	,,	
Vintage 1840	,, 84s.	,,	
Vintage 1847	,, 72s.	,,	

all of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s.; superior Sherry, 36s., 42s. 48s.,; Clarets of choice growths, 36s., 42s., 48s., 60s., 72s., 84s.: Hoch, heimer, Marcobrunner, Rudesheimer, Steinberg, Liebiraumilch, 60s.; Johannesberger and Steinberger, 72s., 84s., to 120s.; Brauneberger, Grunhausen, and Scharzberg, 48s., to 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontignac, Vermuth, Constantia, Lachrymæ Christi, Imperial Tokay, and other rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; very choice Cognac, vintage 1805 (which gained the first-class gold medal at the Paris Exhibition of 1855), 144s. per dozen. Foreign Liquers of every description. On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,
London, 155 Regent street, W.; and 30 King's road, Brighton.
(ORIGINALLY ESTABLISHED 1667.)

Fine Old Port, Twelve Years in

Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clarets, 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints; 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts; 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

A Cup of Coffee in One Minute.

—DUNN'S ESSENCE of COFFEE, 1s. and 2s. pe bottle. May be had everywhere. Warranted to keep good in any climate.

J. Clarke (late Thompson), Surgical

Instrument Maker, Cutler, Truss and Bandage Maker, 225 Piccadilly, near Regent's Circus, W.

Weiss's Illustrated Catalogue, con-

taining nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first orignated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'The Lancet,' Sept 12th. 1863.

Riddell's Patent American

KITCHENERS cure Smoky Chimnies, save half the fuel usually consumed, yield a plentiful supply for hot water, require no brick work setting, are fully equipped with cooking utensils, and will roast, bake, boil, steam, fry, or broil better than any other kitchen range, and may be seen in operation daily at 155 Cheapside, London.

Riddell's Patent American Heating

STOVES. cure Smoky Chimnies, require no brick work setting, and are cheap, convenient, and very economical.

Riddell's Patent Slow Combus-

TION STOVES, for warming Churches, Entrance-halls, Schools, &c., will keep in full action from 12 to 30 hours without attention. A building of the cubic capacity of 20·000 feet may be thoroughly warmed at an expense for fuel of 5d. per day.

Riddell's Patent Slow Combustion

BOILERS for warming Conservatories, Hot-houses, Warehouses, Churches, or Private Dwellings, by the CIRCULATION OF HOT-WATER, will keep in full action 12 to 24 hours without attention, therefore dispensing entirely with watching or night work, require no brick work setting, and are PERFECTLY SAFE.

JOSEPH HADLEY RIDDELL, Stove and Boiler Manufacturer and Hot Water Fitter, 155 Cheapside, London, E.C.

Prospectuses free on application.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

NOTES ON SOME OF THE CASES UNDER THE CARE OF

Dr. Greenhalgh, Physician-Accoucheur to the Hospital.

The first two patients that we visited were suffering from one of the consequences of endo-metritis—namely, a narrowing of the cervix uteri, and a contraction of the os, for the removal of which Dr. Greenhalgh was using a cylinder stem, made of silver, and of sufficient length to traverse the cervical canal, and enter the cavity of the uterus.

This instrument he finds most valuable in such cases. It is well rounded at its summit, so that there is no sharp point or angle to irritate the uterine walls; its sides are also well rounded, and terminate below in a circular plate, which, projecting beyond them, serves as the base of the instrument, and hinders its passing bodily into the cavity of the womb; being a hollowed cylinder. it admits of the entry into its interior of the uterine sound, and upon and by means of this latter it is passed into the womb, where, having a curve for the purpose of adaptation with the axis of the uterus, it is easily retained; the patients expressing themselves as comfortable, and few complaining of *any* annoyance from its employment. To obviate the tendency which it has to slip from the womb, Dr. Greenhalgh, when necessary, has a hook affixed to it in such a manner, that the more the instrument protrudes from the os, the more the hook enters the parietes of the viscus, so that there can be no expulsion of the instrument, and even very little prolapse of it, from the cervix.

There are no perforations in the top or sides of this tube in order that the discharges from the organ may find an exit through the centre of it, nor is it removed during the menstrual periods, Dr. Greenhalgh considering its *retention* at *these* times most beneficial, inasmuch as the menstrual fluid makes its way along the sides of the tube, and by a kind of hydraulic pressure helps to effect the dilatation of the abnormally constricted cervix.

Its retention at the menstrual period costs the patient no additional pain. We believe Dr. Greenhalgh also employs it in certain cases of dysmenorrhœa. Upon the occasion of our visit to the wards under his care, he related the following anecdote, illustrative of the non-inconvenience, nay more, of the comfort, experienced in the wearing of the instrument by dysmenorrhœal patients. A young lady, suffering from severe dysmenorrhœal symptoms, had placed herself under his care some time ago; she was treated by means of this instrument, and expressed herself as being immensely relieved. After a time she discontinued her visits, and Dr. Greenhalgh heard nothing more of her till after the lapse of some months, when she presented herself to him in order to tell him that she was quite well, as there was now no unusual amount of pain with the periods. The patient was a little annoyed that she had *lost* the instrument, having done so, she said, through forgetfulness of its presence; however, upon vaginal examination, it was detected in the uterine cavity, having no doubt worked its way into it while the lady was upon the continent, and to use her own expression, "had been racing over the mountains day after day."

No ill-consequences had arisen from the detention of the instrument in the interior of the womb.

The second of these two cases had had, in addition to the narrowed cervix and os, a thickening, enlarging induration and eversion of the lips of the os, a condition which Dr. Greenhalgh had removed by the application of potassa fusa to the everted lips, until they were completely melted down to their natural size; the cervix and os were subsequently divided by means of the double-bladed hysterotome, which Dr. Greenhalgh has himself devised. He lays great stress upon the necessity of—in instances similar to the present—passing the hysterotome sufficiently high up, so that the os externum, the os internum, and the cervix itself, may be all well divided, the incision being made to extend well into the body.

We examined the condition of parts, and found the cervix fully open; the os likewise patulous, and its lips no longer enlarged, everted, and thickened; the structures being restored to their original condition, as nearly as could possibly be expected, in the short time the woman has been under treatment.

In the next bed was a patient, who, when pregnant and at about her full time, had slipped in the street; had, after her fall, scarcely been able to get home, owing to the excessive prostration and pain which ensued, and had been then obliged to keep her bed for some time. The subsequent history was, that she had had a copious discharge from the bowel, and that the bones and flesh of a child escaped in this discharge; the scalp, with some of the hair attached, and the bones of the head being the last to come away.

An interesting feature in the case is, that the flesh was decomposed, although only three months, we believe, had elapsed from the time of the accident to the passage of the fœtal remains.

From the entire history of the case, Dr. Greenhalgh considered it to be one of ruptured uterus, after which accident the child had passed into the abdominal cavity, had there acted as an irritant, and having excited certain changes in the bowel, had made for itself an aperture of exit, and finally worked its way through the opened bowel; this he thought to be the nature of the case, rather than that there had been extra uterine fœtation. The fourth patient was labouring under that condition named by Gooch "irritable uterus," but to which Dr. Greenhalgh prefers to apply the term hyperæsthesia of the uterus, as being more indicative of the actual lesion of the organ.

Various remedies had been tried, but none had succeeded so well as blistering immediately over the site of the left ovary—which was also engaged in the hyperæsthesia—and the cuticle having been removed, sprinkling the bared cutis with the powder of morphia. The woman was unmarried; she was likewise affected with irritability of the stomach. Vaginal examination declared nothing but the exaltation of sensibility, not of the uterus and left ovary alone, but also of the upper part of the vagina.

Case five was that of a woman of about the middle age, in whom epithelioma of the neck and mouth of the womb had become developed.

There was the usual history:—An increase of the natural moisture, gradual, and proceeding to such a length as to amount, in a short time, to a positive discharge, which was different from all other secretions or discharges from these parts that the woman had ever before seen; an augmenting of this till it became excessive, and began to prove a drain to the constitution; a greater "loss" at the menstrual period than the woman was accustomed to have; and, as the disease advanced, hæmorrhages, brought on by forced efforts in emptying the bowels or the bladder, from sexual intercourse, or from mere vaginal examinations. These hæmorrhages were not continuous, but were replaced by the peculiar watery discharge so characteristic of the disease.

The name commonly applied to this epitheliomatous state of the parts, is cauliflower excrescence of the uterus, from the peculiar conformation of the diseased mass.

As sequelæ of the floodings, and of the profuse watery discharges, anæmia and its attendant evils supervene; dyspepsia, preceded by derangement of the stomach and bowels, sets in, and the woman in some instances becomes

anasarcous. Death is very often traceable to serous effusions into some one or other of the serous cavities.

It was remarkable in this case how well the woman looked, though there was pretty extensive disease of the os and cervix; of the latter so much *posteriorly* as almost to implicate the vagina, and make operative procedures of doubtful utility; *anteriorly*, however, the finger could be passed above the growth, and brought into contact with healthy uterine tissue, as well as distinctly swept around the mass of the disease, showing a complete isolation of it, at least in this direction, from the vaginal wall.

The sensation communicated to the finger conveyed the idea that the tumour was irregular and tuberculated—that is, that the surface consisted of a number of little eminences with intervening depressions, and that all were covered with a thin, delicate, and fine membrane; it is the same sensation as would be perceived were the finger passed over the maternal surface of the placenta, when it is surcharged with blood. There was little, if any pain experienced by the patient from our examination, the tumour not being possessed of sensibility.

This excrescence should be diagnosed from a fungating cancer, which may be done by attention to the general symptoms; in the former these symptoms arise from anæmia, in the latter from the irritation of the open malignant surface; again, the excrescence is comparatively soft, readily moveable, admits of isolation, and can be ascertained to have its origin from the lips of the os; in microscopic character it likewise differs from the true form of cancer.

The edge of the placenta somewhat resembles it, but then the existence of pregnancy will clear up this difficulty to diagnosis; however, the two conditions may exist, and complicate that diagnosis; by attention to the state of the os, to the congestion or otherwise of the vagina and labia, and to the position in which the placental souffle is audible, we may arrive at a just conclusion.

We must likewise be careful not to be led into the error of mistaking the disease for polypi, or for fibrous tumour, from which it is to be recognised by its tuberculated surface, by its softness, by its readiness to bleed when touched, and by its not being pediculated.

In the bed next to the patient of whom we have been speaking was another labouring under the same complaint, but in such an advanced stage that all operative measures were precluded. She had been admitted some time previously, completely exsanguined, but under treatment (preparations of iron, and the most nutritious diet), she had regained a little colour in the gums, lips, and inner or mucous surfaces of the eyelids. She was not emaciated to any marked degree, and the face was round and plump, though blanched.

At times the hæmorrhage was so severe, that vaginal plugging was necessitated, and Dr. Greenhalgh had in the first instance resorted to the tampon of cotton wool, but on all subsequent occasions put in practice his own method for the arrestment of the bleeding; this method consists in passing into the vaginal canal an elastic bottle, which is covered with spongio-piline, and admits of inflation.

The patient pronounced this latter plan as immeasurably superior to the former, inasmuch as she was relieved of the hæmorrhage without the cost of pain, while the bottle was worn, or when it was being withdrawn. The facility also with which the bottle can be introduced and removed is another great advantage that it possesses over the cotton wool.

The next bed was occupied by a woman, a patient suffering from pelvic cellulitis. It seemed that she had had repeated attacks of inflammation "in the lower part of the stomach," that at times there had been profuse "matter discharges from the front passage," and that the inflammation had been attended with shiverings.

From the history of the case, and the length of time over which it extended, without the manifestation of any decidedly cancerous indications, either locally or generally, and from the absence of fœtid, thin, ichorous discharge, the probability of the affection being malignant was laid aside. Vaginal examination enabled us to detect the upper part of the vagina to be thickened and indurated, and to be the seat of fibrous consolidation, in the midst of which the os uteri was imbedded; the tissues around the uterus were likewise involved in the thickening and induration, but there was no ulcerated point; a circumstance very strongly adverse to the probability of the affection being malignant.

But independent of this there was not the hard, strong, dense unyielding, undefined and rugged consistence of schirrhus.

Pelvic cellulitis is essentially a phlegmonoid inflammation, and very frequently terminates in suppuration. In the inflammatory processes are involved, the cellular tissue of the pelvis, the broad ligament, the ovary, the Fallopian tube on one or both sides; even the uterus itself, or one part of it, may share in the lesion. The complaint in its acute stage may terminate in resolution, in that condition of induration and matting together of the tissues, such as exists in the present instance, or in the formation of matter.

The abscess—if the inflammatory processes proceed to suppuration—may open through the abdominal walls, and so find exit externally, or through the vagina, the large intestine, the bladder, or the womb; sometimes, also, it has been known to burst into the peritoneum, when, by exciting acute, rapid, and intense inflammation of the sac, it causes death. It is not, however, always circumscribed at its commencement, but may burrow into the cellular tissue until it makes for itself an aperture of exit.

When the matter bursts into the colon or rectum, it may occasion fatal results by the dysentery which may be induced. Such cases are fortunately rare.

If the abscess point in a favourable direction, we should make an incision down upon it as early as possible, for the purpose of preventing any burrowing, or a determination of the matter to a position of danger.

In every instance in which we deem an incision necessary, we must must bear in mind to have it free, and sufficiently extensive to allow a thorough emptying of the sac; and, even should the natural opening—that is, the opening formed by the spontaneous rupture of the abscess—be so small as only to admit of a dribbling away of the purulent contents of the abscess, we should not—provided the aperture be not in an inconvenient or dangerous situation—hesitate to enlarge it, give free vent to the matter, and in this manner guard against fistulæ.

Pelvic cellulitis, though occurring most frequently in parturient women, is yet found to exist in those who have never borne children, and at periods other than the parturient, nor are the unmarried exempt from it.

The causes assigned are excessive venery; improper use of injections, vaginal or rectal; blows, falls, cold, or even fright; sudden check of the lochia or of the milk; protracted labour; too long continued pressure of the fœtal head, too great—it may not be of very long duration—compression of the parts, from the child's head being larger than ordinarily, and, as a consequence of the violence, inflammation.

Dr. Churchill says:—"It does occasionally occur, however, quite independently of external causes. In a patient I had an opportunity of treating, it came on immediately after the cure of a severe attack of acute uterine leucorrhœa, without any appreciable cause. It may also be caused by an extension of inflammation from the external parts of generation."

Dr. Clintock in his "Clinical Memoirs on Diseases of Women," records 61 cases of abscess, nearly half of which were in primiparæ.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of Candidates who passed the Major Examination on March 16th, as Pharmaceutical Chemists:—Antonio A. Ferreira, Rio de Janeiro; George R. Warren, Ware; Albert Cooper, Yeovil; Abraham J. Dyer, Gosport; William S. Greaves, Ironville; John Hamp, Wolverhampton; Martin Magor, Truro; John Reece, Rotherham; David P. Saer, Pembroke Dock; James Swenden, Darlington.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. VII.

NITRIC ACID. — The British Pharmacopœia adopts the acid of the Edinburgh and Dublin Colleges, which has the density 1·5 ; the London acid had the density 1·42.

The advantages of this change are doubtful. An acid of the last-named strength is a definite and very stable compound of one equivalent of the real acid and four equivalents of water, which can always be obtained with ease by the redistillation of either a stronger or a weaker acid. The Pharmacopœia assigns the formula 3 H O, 2 N O 5, to the acid having the density 1·5 ; but although a definite hydrate, it is far less stable than the weaker acid. It is obtained with more difficulty, it fumes disagreeably in the air, absorbs water, and on exposure to light becomes brownish from decomposition, nitrous acid being formed, and oxygen liberated.

For all pharmaceutical purposes, the London acid was sufficiently strong, but when employed as an escharotic, it was necessary to use the acid of the density 1·5. It would, perhaps, have been better to have introduced both acids. Three nitric acids would not have been more absurd than three acetic.

The process given for obtaining nitric acid requires no comment. A mixture of two pounds of nitrate of potash and seventeen fluid ounces of sulphuric acid (corresponding to about one equivalent of the former, and two equivalents of the latter) is to be distilled. A gentle heat is at first employed, but towards the end of the operation the temperature must be increased so as to liquefy the contents of the retort. The results of the decomposition are, of course, nitric acid and bisulphate of potash.

An acid of the Pharmacopœia strength may be as easily obtained by distilling at a low temperature one part (by measure) of the 1·42 acid, and two parts of sulphuric acid.

The tests of the Pharmacopœia are intended to prove the absence of sulphuric acid and chlorine ; the former would give a precipitate with chloride of barium, and the latter with nitrate of silver.

As we have said before, the strength of the dilute acid has been somewhat increased, but not to such an extent as to require any alteration of the dose.

ACIDUM NITRO-HYDROCHLORICUM DILUTUM.—It is necessary to say but a very few words on this compound. When one part of strong nitric acid and two parts of strong hydrochloric acid are mixed together a yellow liquid is produced about the exact nature of which chemists are not agreed. The fact is that some nitric acid is decomposed, a portion of the oxygen of which combines with some hydrogen of the hydrochloric acid to form water, some chlorine being set free, while another portion of chlorine unites with the lower oxide of nitrogen to form a compound or compounds the exact nature of which, as we have said, have not yet been determined.

The dilute acid of the Pharmacopœia is, however, probably only a simple mixture of nitric and hydrochloric acids, the nitric acid being diluted with thirteen times its bulk of water before the hydrochloric is added. This mixture is directed to be preserved in a stoppered bottle, although a mixture of the concentrated acids cannot be so kept, unless the bottle is of unusual strength ; and we may mention by way of caution, that a bottle of this latter mixture sent to a patient for use in a bath, on one occasion burst in a drawing-room with disastrous effects to the furniture.

ACIDUM PHOSPHORICUM DILUTUM.—The strength of this acid has been increased in the British Pharmacopœia. In the London Pharmacopœia it was ordered to have the density 1·064 ; it is now to be 1·08. The alteration need not affect the dose, which may be the same as was formerly prescribed.

The phosphoric acid intended by the Pharmacopœia is the ordinary tribasic acid (orthophosphoric acid of recent writers), the formula for which is 3 H O, P O 5. It is directed to be made by oxidising phosphorus by means of nitric acid. Four ounces of nitric acid diluted with ten ounces of water, are placed in a retort with four hundred and thirteen grains of phosphorus and a gentle heat is applied. The distillate at first consists of nitric acid with some phosphorous acid. This is returned to the retort and the distillation is continued until all the phosphorus is dissolved. The second distillate is rejected, and the contents of the retort, which consist of the phosphoric acid, with nitric acid, and some nitric oxide in solution, are transferred to a platinum or a porcelain capsule, and evaporated to the consistence of a syrup in order to expel the above-named nitrogen compounds. The syrupy solution is then diluted with sufficient distilled water to make a pint.

The special characteristics which distinguish the tribasic phosphoric acid are, that it gives a canary-coloured precipitate with nitrate of silver, and produces no precipitate with solution of albumen. If, however, the evaporation be carried too far, an acid may be obtained which, in consequence of the formation of some pyro- and metaphosphoric acids, will give a paler precipitate with nitrate of silver and a precipitate with albumen. Should this happen it is only necessary to boil the diluted acid for a short time in order to re-convert the pyro- and meta- acids into the tribasic acid. Water may then be added to make up the original pint.

Phosphoric acid is often made by acting on bone earth with sulphuric ac d, but the acid so obtained may be contaminated with arsenious and sulphuric acids. The presence of the former will be detected by sulphuretted hydrogen, and the latter by chloride of barium, the solution of which must be acidulated with nitric acid, although the

Pharmacopœia does not say so. Chlorine will be discovered by the acid solution of nitrate of silver, and if any nitric acid is present it will communicate a dark colour when the acid mixed with an equal volume of pure sulphuric acid is cautiously added to a solution of sulphate of iron.

The Pharmacopœia directs the strength of the acid to be ascertained by converting it into phosphate of lead. Six drachms evaporated with 180 grains of litharge will leave a residue which, after ignition, should weigh 215·5 grains. This is a much better method than that given in the London Pharmacopœia.

ARMY REPORTS.

No. 2.

STATISTICAL, SANITARY, AND MEDICAL REPORTS FOR THE YEAR 1861.

ISSUED BY THE ARMY MEDICAL DEPARTMENT, OCTOBER, 1863. Pp. 552.

Report on the Gun-shot and Sabre Wounds of Invalids sent to Fort Pitt during the Years 1860 *and* 1861. By Thomas Longmore, Esq., Deputy-Inspector General, and Professor of Military Surgery to the Army Medical School. Pp. 30.

(Continued from page 167.)

It is gratifying to see that an improvement is taking place in the general health of the army, always supposing that every source of error is eliminated, by the gradual reduction of the mortality in 1861, contrasted with 1860. In the former year the army contrasts favourably with the civil male population in the mortality from all causes, as in only three grades of the army is the mortality greater than among civilians, viz., the Military Train, 9·33; Depôt Brigade Royal Artillery, 13·83; Depôt Battalions, 11·38; civil male population, England and Wales, being for that year 8·85 per cent.

Are the causes of this excess in these branches of the service remediable? for if so, we may hope for an improvement in future reports. At page 17 we have a table of miasmatic diseases, viz. — 1st, eruptive fevers; 2nd, paroxysmal fevers; 3rd, continued fevers; 4th, dysentery, diarrhœa, and cholera; 5th, sore throat, and influenza; 6th, ophthalmia; 7th, rheumatism. We shall take the third heading, viz., continued fevers, as an illustration of the various degrees to which the different branches of the service are affected by miasmatic diseases.

Annual ratio per 1,000 *of mean strength attacked by fever*:

Household Cavalry, 5·74; Dragoons and Dragoon Guards, 27·08; Royal Artillery 12·38; Military Train, 20·36; Foot Guards, 29·77; Infantry Regiments, 19·24; Cavalry Depôts, 36·33; Depôt Brigade, Royal Artillery, 18·70; Depôt Battalions, 25·40.

Strange to say that in the branch, viz.,—Cavalry Depôts,—where the greatest number is attacked, the mortality is least, being *nil*. In all, the mortality is wonderfully small, the highest being 64 per 1,000 in the Depôt Battalions.

The important question is suggested, what are the causes of the disparity in the number attacked? 1st. Is it the kind of duty? 2ndly, Is it a difference in the habits of the men? 3rdly, Is it the sanitary condition of the barracks? for it being understood that all recruits are picked men, and consequently all start under similar conditions, the disparity mentioned may be capable of explanation, and if so, the causes are removable, and we cordially agree with Dr. Balfour, the editor of the Statistical Department, who finishes his report thus:—

"An important field of inquiry is suggested to the Medical officers of sickly corps into the causes to which this great difference in the condition of the regiments is to be attributed."

The best climate for invalids of a tubercular diathesis, is yet undetermined, and, although the result of a statistical table can scarcely settle the question, still, as we have no other data to go upon, we must, until we have better, deal with the information as we have it, adopt conclusions, and act upon them with reason; and as no other country is likely ever to possess the extensive opportunities which England now enjoys for enabling statistical tables to be formed, we prize the more those presented to the public in this and similar Blue Books. We shall take as our standard of comparison the mortality of the troops in the United Kingdom from tubercular diseases, but as our space is limited, we shall give only the number admitted into hospital, and the number of deaths in the ratio per 1,000 men. The native troops in North China present the most favourable figure, the number of admissions being 2·4, deaths, 1·03. St. Helena comes next, being 2·9 admissions, and no deaths; Mauritius next, 4·2 admissions, 1·04 deaths. Australasia gives the highest number of admissions among Europeans, 19.8, deaths, 1·10, a country hitherto considered favourable to the recovery of tubercular disease, which opinion the low ratio of deaths helps to support, although the large number of admissions shows that the climate of Australia does not tend to prevent the deposit of tubercle; we are, nevertheless, inclined to recommend the Australian climate, and more especially as the long sea voyage seems to be very favourable to the amelioration of tubercular disease. We do not discuss here the proportionate merits of European localities. We have by these tables a sad proof that the black races are not exempted from this all-destroying disease, for both at the West Coast of Africa, and the West India and Windward Islands, we see the following melancholy list, and we are induced to ask, is this high rate of mortality the consequence of the same care and the same sanitary measures not being bestowed upon our black troops, as are bestowed upon our white troops, for in Jamaica, among the white troops, the admissions are only 4·7, and no deaths; the Windward Islands, admissions, 14·3, deaths, 1·59; whereas, in Jamaica the mortality stands thus with the black troops: admissions, 14·9; deaths, 5·60; the Windward Islands admissions, 29·8; deaths, 8·94; but at Sierra Leone, the Gambia, the Gold Coast, the white and black races suffer nearly alike. Sierra Leone, white admissions, 5; deaths, 4; black admissions, 13·5; deaths, 10·81. Gambia white admissions, 11; deaths, 5; black admissions, 25·5; deaths, 11·60; Gold Coast white admissions, 2; deaths, 2; black admissions, 96·5; deaths, 6·5.

Our suspicions on this point are corroborated by turning to the 'Sanitary Report on the Gold Coast,' at p. 268, where the Staff-Surgeon states "the barracks to be invariably unfavourable to health." Means for ablution, and facilities for varied employment working, seem to be generally absent at these stations.

If the opinions expressed in the detailed reports were collected, the aggregate would cumulate in an observation made at page 272, "representations have since been urged, and satisfactory results may be anticipated." Vain hope, we say, on the part of the Medical Sanitarian! Years may elapse, and hundreds of avoidable deaths may occur before his benevolent suggestions are, if ever, attended to, notwithstanding all the parade of Military Sanitary Reform, thrown as dust into the eyes of the credulous English public.

That we do not exaggerate in these matters is proved by the statements of F.R.G.S., "at St. Mary's, Bathurst, the military hospital is close to the swamps. The place is murderous. There is a sick ward upon the ground floor! One night on the ground floor is certain fever in most parts of Tropical Africa, and that ground floor is, like the latrinæ and other offices, frequently under water." Page 155, again, "when prophylactic hygiene shall become associated with proper therapeutic treatment, when the lands shall be cleared, and especially when only the stations above fever level shall be used by Europeans, they will find themselves as much at home in Africa, as in Southern Europe." Page 182, again, to show the advantage of locality at Free town in

Sierra Leone, the barracks are placed on high ground. "During the terrible yellow fever of 1859, the only fatal cases were those brought up from the low land," p. 249.*

It has been suggested by Dr. Patrick Fraser, and we endorse the recommendation, that medical officers should append to these reports, meteorological tables of the places at which they are stationed, so that after a period of say seven† years, reliable data would be obtained; and as an earnest of what may be done in this direction, we point to a table by Dr. Lamprey at p. 201, and an abstract from Jamaica, at p. 256, also from the Mauritius at p. 273.

The obstacle to this proposal being fully carried out, would doubtless be the expense, as the instruments ought to be supplied by Government, and science goes to small account if money be required out of the public exchequer.

(To be continued.)

IRISH MEDICAL "MEMS."

(From our Dublin Correspondent.)

The Bill for the superannuation of the Poor-law Medical officers was lost last session in its passage through Parliament by the apathy of our Irish members, and, taught by experience, our Medical men are bestirring themselves and forming associations through the country to bring all possible interest to bear upon our representatives. Meagre though the pension will be, yet it is not to be despised, and will be something to fall back on in the decline of life, and will swell whatever thrift and industry have amassed. Justice would seem to establish our claims to such an allowance, but justice is too often but a myth, in these cases, a *vox et præterea nihil.* Dispensary physicians have an unenviable task, hard work and poor pay, and until there is some change devised, dispensaries will still be defined (as they were so pregnantly, some years since, in one of our comic journals,) "*Places where poor people get medicines in their own bottles.*"

Dr. Mackesy, late President of the College of Surgeons, to whom the Poor-law officers are indebted for many improvements and advantages, was elected a Member of the Council of the Royal College of Surgeons, vacant by the election of Dr. Jacob to the vice-presidentship. A dispensary surgeon at Belfast, was subjected, a few weeks since, to one of those annoying and scandalous actions which are so often instituted against Medical men, and from which they can have no redress. Though it resulted in his honourable acquittal, and popular feeling ran high in his favour, and illuminations were held in the town in his honour, yet, gratifying though these marks of respect might be, it could but ill make up for all the anxiety and distress of mind he must have suffered preceding and during the trial.

It was a repetition of the old story. He was sent to visit a young married woman named Rose Drummond, and at her residence committed the alleged assault. The evidence was such a tissue of inconsistencies and falsehoods, that there was no doubt of his innocence. Owing to the general indignation of the populace at the conduct of the Drummonds, they were obliged to leave Belfast, and returned to Glasgow, whence they had originally come, and where they may again, perchance, try their luck.

A paper was read by Dr. Mapother at the last meeting of the Social and Statistical Enquiry Society, which showed some startling facts as to the sanitary state of our city. If his facts are true, it would appear that Dublin shelters within its walls the most wretched civic population on the face of the habitable globe. He has drawn a picture of distress and misery most appalling; wretchedness piled on wretchedness, and forming a sum aggregate of destitution beyond conception. His bills of mortality range fearfully high, yet few cities in the United Kingdom can boast the possession of such charitable institutions as Dublin, or have such a multitude of medical men, so that we have everything that medical appliance can offer. This paper has opened the eyes of our citizens, and remedial measures will now be taken to remove the existing sanitary evils, and it is to be hoped with the same effect as in the English metropolis.

Death has snatched away another distinguished surgeon, Leonard Trant, F.R.C.S.I., and surgeon to the "Cork-street Fever Hospital." Though never figuring in the arena of surgery as a writer, yet he was ever regarded as an accomplished surgeon and skilful operator; and there are numerous cases on record of his success in the operations of lithotomy and strangulated hernia, which would throw into the shade many of the performances of those who profess to be *au fait* at these particular operations. Dr. Wharton, F.R.C.S., has been elected surgeon to that hospital in his place. We have also to record the death of a provincial surgeon of high repute, Dr. John Jacob, of Maryborough, brother of Arthur Jacob, Vice-President of the Royal College of Surgeons of Ireland, and uncle to the proprietor and editor of the 'Dublin Medical Press,' He was proprietor of the Maryborough Lunatic Asylum, and specially devoted himself to psychological pursuits, and held a very high position in public favour. It was believed that some measure would have been brought forward to regulate and improve the lunacy laws of Ireland, but the session is passing by without any allusion to it, and we must live on in the hope that next session it will be taken into consideration.

Medical education is again on the *tapis*, but seems to be making no progression. Medical education may justly be regarded as the chameleon of our Profession. Volumes have been written, endless controversies held, time and words wasted in the attempt to assign to it some definite form and colour, and yet are its hues not merely as undetermined as ever, but seemingly involved in greater obscurity, and borrowing fresh tints from the minds of the different investigators into this vexed question. Having gone through every phase, and been put through all the moods and tenses, we are now *in statu quo* still in search of the philosopher's stone, or of some adamantine sword which will sever at one stroke this Gordian knot.

While some of your contemporaries pandering to the taste and prejudices of your nation, and with that catch-penny spirit which makes them give insertions to offensive advertisements and non-Medical paragraphs, wantonly insult the Irish people by pointing to the number of Irish successful candidates as a proof of the inferiority of the Army Medical Department, it is gratifying to know that we have some independent Medical journal which is willing to give merit where merit is due.

Every Irish Medical man, and every Irishman, whether in Ireland or England, or her colonies, cannot but feel grateful to the Medical Circular for its vindication of our national institutions, and for your tribute to the efficiency of our Medical and Surgical Schools. There has been for too long a breach between the sister islands, and though some, for their own purposes, may wish to keep the old wounds open, yet it would be wiser policy to heal them at once, to fuse the people as much as possible together, and not encourage such exclusive nationality as to have the Royal Colleges of Surgeons of London and Dublin as separate from one another as the antipodes, and their respective members at loggerheads. When we remember that we are all engaged in the perfection of a science, all these sectarian and political jealousies which have been so long the disgrace of both countries and the curse of our own should be discarded, we should shake hands as friends and brothers, as children of the same race and stock, and be united for our Profession's weal, for unity is strength.

* Wanderings in West Africa.

† Mr. Glaisher says fifty years is not enough!

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Under the title of "Clinical Conferences in Midwifery," Dr. GRAILY HEWITT commences a series of discourses on some Practical Points in Obstetric Medicine, his present subject being the "Management of Tedious Labour." The question has often been discussed whether a tedious labour should be left to the unassisted powers of nature, or whether some efforts should be made to expedite delivery. Dr. Hewitt examines the opinions and statistics referring to both sides of the question, and comes to the conclusion that the safety of tedious labours has been over-rated, and that, in fact, danger both to the mother and the child is generally proportionate to the length of the process. It is impossible, however, to lay down any rule as to the time which should be allowed for the natural efforts; it can only be stated generally that very protracted labours often give rise to laceration of the organs in the mother and to the death of the child. Mr. HENRY HANCOCK contributes the first of a series of papers on "Division of the Ciliary Muscle, with Cases." In the present paper, Mr. Hancock claims for himself the originality of this operation in the treatment of glaucoma and irido-choroiditis, in opposition to the criticisms of a writer in the last number of the 'Dublin Quarterly Review,' who asserts that the operation is not new. Mr. Hancock denies altogether that section of the ciliary muscle, as practised by himself, and the old paracentesis oculi, are identical. Mr. J. JARDINE MURRAY communicates a paper on "Removal by Ligature of Large Subcutaneous Nævi without Loss of Skin," and illustrates his remarks by relating a case in which the operation he describes was successful. The proceeding consists in passing threads, by means of a needle, beneath and around the nævus, and then tightening the threads, so as to cut off the supply of blood to the growth. The principle of this operation has long been adopted, but there are some peculiarities in the details, which are described by means of diagrams.

THE 'MEDICAL TIMES AND GAZETTE.'

DR. GARROD continues his "Lectures on the British Pharmacopœia," beginning on this occasion with the salts of lithia, which Dr. Garrod was himself instrumental in introducing into Medical practice. The peculiarities of the salts of lithia as medicines, are that they are readily absorbed by the stomach and pass through the kidneys, that many of them are powerful diuretics, that lithia combines readily with uric acid, and that it seems to be efficacious in the treatment of gout. Hemidesmus is a new drug, said to possess similar properties to sarsaparilla, but without any known efficacy. Matico is an astringent in hæmorrhage, and is obtained from a kind of pepper the *Artanthe elongata*. The permanganate of potash is a powerful antiseptic agent, but its use, when administered internally, is not very obvious. The Valerianate of Zinc is not made from Valerian root, but from fousel oil, or amylic alcohol, which, when oxidised, yields valerianic acid. In estimating the value of valerianate of zinc, it is difficult to distinguish between the properties of the zinc and those of the acid; but some authorities consider that valerianic acid does not possess the same medicinal properties as the valerian root. MR. LE GROS CLARK contributes a short clinical lecture on "Amputation between the Astragalus and Navicular Bones (Chopart's operation) and on Re-section of the Knee-joint," his remarks being illustrated by some cases which have occurred at St. Thomas's Hospital. DR. T. DEVILLE offers some anatomical observations on the "Lingual Glands," otherwise known as the Glands of Blandin or Nuhn, and the Glands of the Tip of the Tongue (Henle's), and the Glands of the Frænum (Goodsir's). The description is accompanied by an illustrative engraving of the parts seen on dissection. DR. CHARLES MURCHISON relates a "Case of Pyæmia simulating Enteric Fever, with acute Necrosis of the Ilium, Sternum and Acromion, and a Pulsating Abscess in front of the Sternum." The case was fatal, and was anomalous in its history and progress, as some of the symptoms of enteric fever were absent, and there had been no injury or wound to account for the pyæmia.

REVIEW OF BOOKS.

A Practical Treatise on Diseases of the Skin in Children: from the French of Caillault. Second Edition. With Notes, Appendix, and Formulæ. By Robert Howarth Blake, M.R.C.S.E. Pp. 331. London: Churchill and Sons. 1863.

The subdivision of Practical Medicine into innumerable specialities, has its advantages and disadvantages; among the former of which may be mentioned the opportunities afforded for particular studies, by the collection of a great number of cases of the same kind, and the consequent expertness which is acquired in their treatment: among the latter may be urged the inconvenience of distributing over a host of varieties, a science which is founded essentially on the same principles, and ought therefore to be studied in its integrity. At first sight it would appear that the department of skin-diseases forms a sufficient speciality of itself, and that if the skin-diseases of children were to be elevated to a distinct position, so might also the skin-diseases of old persons, or the skin-diseases of males and of females, and so forth. Still, we must admit that M. Caillault has a right to attention for the special department which he illustrates, the more particularly as his work is entirely of a practical character, and founded on the results of extensive experience in the Hospital for Sick Children, in Paris. Mr. Blake has done good service by his translation of the book, and one of its most useful features is the appendix containing the doses of various medicinal agents for the skin-diseases of children of from two to four years of age. There is also an index of contents.

The Prescribers' Analysis of the British Pharmacopœia. By J. Birkbeck Nevins, M.D. Lond., Lecturer on Materia Medica in the Liverpool Royal Infirmary School of Medicine. Pp. 91. London: Churchill and Son. 1864.

This is a very little book, but as it is intended for a pocket companion, its smallness will perhaps be considered one of its chief merits. Its object is to exhibit in a short compass the differences existing between the New Pharmacopœia and the old ones, and to enable the practitioner, at a glance, to observe the nature of the changes which have been made. The necessity of such a guide is obvious enough when it is recollected that many of the old names are retained, while the strength of the medicines has been

materially altered. For instance, the Liquor Ammoniæ Acetatis is now five times as strong as the preparation of the same name in the Ph. L., but the tincture of Aconite is only one-third of the strength of the Ph. L., one-fourth that of the Ph. D., and less than one-fifth that of Fleming's tincture; while the solution of hydro-chlorate of Morphia is only half the strength of the Ph. L., although identical with the D. and E. Dr. Nevins gives lists of substances and preparations which have been added in the British Pharmacopœia, and which certainly do not present a very numerous list like that of the articles which have been expunged, and most of which we can very readily part with. A short list is also given of medicines in modern use, which have not been introduced in the Ph. B., but as we find among them such medicines as Sarracenia purpurea, Cotyledon umbilicus, and the hyponitrites of potash and soda, we do not know that much fault can be found with the compilers of the Ph. B. for their omission. The doses of the new medicines are also appended, with short descriptions of their properties, and the book concludes with some formulæ illustrating the alterations required in prescribing the new or altered medicines and preparations, and exhibiting the symbols now employed.

The Teeth in Health and Disease: with Practical Remarks on their Management and Preservation. By Robert Thomas Hulme, F.L.S., M.R.C.S.E. Pp. 236. London: H. Baillière. 1864.

The lucrative nature of the pursuits connected with Dental Surgery has called forth a proportionately large number of professors of the dental art, and many, unsatisfied with the substantial rewards of their calling, have honourably entered the field of Medical literature, and explained in scientific or semi-scientific language the principles on which their operations are conducted. Among the numerous contributions to this branch of letters, the treatise of Mr. Hulme is one of the best. The writer is so well established in his Profession that any work coming from his pen must command attention and respect for its scientific character, but it is written in an easy style, is full of illustration and anecdote, and will be read with interest even by the general public. Mr. Hulme begins his book with some preliminary remarks upon the use of the teeth in speech and in mastication; then describes their origin, development, and structure; and passing on through the history of the temporary teeth, with their irregularities, and the complaints with which their eruption or their decay is often associated, he comes to the important topic of the permanent teeth, and the discomforts and diseases which their maladies too often entail upon the human race. On the common theme of toothache, the remarks of the author are sensible and instructive; the questions of extraction or non-extraction, of stopping, of the removal of stumps, and many similar matters, being all discussed in a practical style. The dangers incidental to erroneous treatment in these particulars are clearly pointed out, and plain rules are laid down for the guidance of all who may unfortunately be under the necessity of seeking advice for the irregularities or diseases of their dental apparatus.

Phthisis and the Stethoscope: or the Physical Signs of Consumption. By Richard Payne Cotton, M.D., Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. Third Edition. Pp. 104. London: Churchill and Sons. 1864.

The appearance of a third edition of this little work proves that its merits are duly appreciated by the Medical Profession, and it is indeed a very useful guide to the practical study of the physical signs of consumption. The difficulty which the inexperienced auscultator has to contend against, in addition to the complexity of the morbid sounds themselves and the variety of their causes, is the obscurity in which the subject is often wrapped by the over-refinement of some Medical writers. The book of Dr. Cotton, however, is practical throughout, and while all the signs described by various authors, are duly noticed, their comparative value as aids to diagnosis are continually tried by the test of experience. As an instance, we may refer to the remarks on pectoriloquy, a sign which has been very minutely described, and which no doubt is very valuable when it really exists. But Dr. Cotton believes, and as we think very justly, that the conditions necessary for perfect pectoriloquy are very seldom observed, and that this sound is often confounded with bronchophony, thus giving rise to serious errors in diagnosis. In accordance with a recommendation offered by one of the critics of his former edition, Dr. Cotton has added to the present a supplementary chapter on the physical signs indicative of arrest or improvement of the pulmonary disease, in the several stages of phthisis. This part of the subject is extremely interesting, especially at the present time, when the curability of consumption is very generally admitted, and it is treated in the same clear and simple style as that which characterises the rest of the book.

GENERAL CORRESPONDENCE.

THE LECTURE SYSTEM.

To the Editor of the Medical Circular.

Sir,—I beg to endorse every word in "Vigil's" able letter on our lecture system. He does not of course allude to clinical lectures, which, if in part catechetical, are of incalculable value to the diligent student. But with regard to the regular classes, why have we them? Will a man become a chemist, anatomist, botanist, a physician, or a surgeon, by attending lectures? I recollect it often said in my student days that, "such a man was working too hard to attend lectures," such men, of course, preferring the school where no roll-call existed. They paid for their lectures, or rather certificates, which payment appears to be the chief end of lectures, and devoted the time to practical study. Goodness knows now, that books are more plentiful than blackberries.

It is greatly to be desired that we had more of practice, and less of theory in our teaching; our young men would start under fewer difficulties, and with more confidence, and it need not be said, with more safety to their patients.

The number of mistakes which theoretical young men make at first, is known only to themselves. If, Mr. Editor, you take up this serious matter, in your able and independent style, it may lead to some good.

Yours, &c.,

Subscriber from the Beginning.

Dublin, March 16, 1864.

The Active Principle of the Calabar Bean.—Two German chemists, Jobst and Hesse, of Stuttgart, have by their researches determined that this is exclusively contained in the cotyledons. They have obtained it by dissolving in ether the residue left by evaporation of an alcoholic solution. The ether solution, in its turn evaporated, leaves the active principle of the bean, which these chemists propose to call *physostygmine*, from the botanical name of the plant, *physostygma venenosa*. It has, however, been suggested that *calabasine* would be as appropriate, and a far more convenient name. Two drops of an aqueous solution of the alkaloid in ten minutes caused contraction of the pupil to about a twentieth of its diameter, it remaining in this state during an hour, and recovering its normal condition in from four to six hours. Taken internally, the *physostygmine* is as poisonous a substance as the most dangerous cyanides.

The Yeatman Hospital, Sherborne.—A meeting of the Committee has decided upon the plans, and have agreed with a builder for the erection of this hospital. It is also agreed that six trustees shall be appointed, and that a code of rules based on those of the Bridgwater Infirmary shall be adopted for the government of the Institution.

THE MEDICAL CIRCULAR.

WEDNESDAY, MARCH 23, 1864.

MEDICAL EDUCATION.

The love of ancient institutions and the horror of centralisation which characterise the British nation, have, in many cases, obstructed the progress of improvement by permitting the continuance of abuses even after they have been proved to be such. Hence the Medical Act of 1858, while it apparently conferred great powers upon the Medical Council, made it at the same time comparatively useless by tying its hands in respect to the reform of the Medical Corporations. It therefore happens that nearly all the anomalies of the pre-existing systems of education and examination have been strengthened and confirmed by the measure in question, and any attempt at uniformity is necessarily made to take a downward direction, because, while some of the educational and licensing bodies are aiming at raising the standard, a few are determined to keep it depressed, and the minority is strengthened by the force of custom, and usage, and vested right. The uniformity affects only the lowest standard, leaving all the higher to shift for themselves.

One monstrous and fundamental error in the constitution of most of the existing Medical examining boards is to be found in the practice of making the salaries of the examiners dependent upon the number of successful candidates whom they turn out upon the public, and although we have nothing whatever to allege against the personal honour of any of the gentlemen who may be exercising the function of examiners, yet it is obvious that the consideration to which we now allude is not without its weight in certain quarters; and, indeed, we have had notorious and flagrant instances, in very late years, where certain collegiate institutions have sprung up suddenly from poverty to comparative wealth by the sale of diplomas on easy terms to all who chose to buy them. The only exceptions to the rule of paying the examiners according to the number of successful candidates is to be found, we believe, in the College of Physicians and the University of London, although there is no great merit in this respect to be attributed to the latter body, when it is recollected that its funds are supplied in great measure by the State.

Another very objectionable feature in the present system of Medical examination, and one which the Medical Council is powerless to assail, is the examination of candidates for diplomas by the same persons who have been previously their teachers. This plan is adopted principally at certain Universities, and although, as in some former remarks, we have nothing to urge against the personal honour of the Examiners, the practice is altogether indefensible. We need scarcely remark that the proposal that diplomas should be granted from the results of class-examinations, conducted by the Professor of each class, is still more objectionable, even although an Assessor should be added in order to keep up appearances.

Having thus lightly touched upon some glaring defects in the present system of examination, we cannot shut our eyes to the fact that the teaching at some of the Medical schools is not such as to attract students, or to engage their attention. In many cases the lecturers are too much engaged in private practice to enable them to devote the necessary time to the instruction of the students; but, in other instances, and these are unfortunately very numerous, the lecturers do not possess the qualities necessary to make them efficient teachers. While we fully admit that the choice of Medical officers to our hospitals and Medical schools is generally very fairly made, and falls, in most cases, on the most deserving candidates, yet, paradoxical as it may appear, the very qualities which shine most conspicuously upon a list of testimonials, are often entirely unattended with any capacity for teaching, and may even be inconsistent with such an avocation. In fact, the very profundity with which a given professor may have investigated his speciality, often renders him quite unable to teach it; because many of the students who resort to his instruction are necessarily entirely ignorant of the branch of science which he professes, and can no more derive information from his elaborate discourses, than the baby just weaned from the breast can derive sustenance from solid meat. The duty of a good teacher is to place himself for a time, on a level with the capacity of the learner, and thus to lead him from the first steps of science progressively to those which are more difficult. *Non omnia possumus omnes:* each person has different gifts bestowed upon him, and without wishing to make any personal allusions, or to mention names, we have known distinguished surgeons whose operations were the admiration of Europe, who failed utterly in imparting instruction by their lectures; and profound chemists, whose discoveries shed lustre on modern science, who rendered their fascinating subject utterly wearisome by their monotonous and unimpressive delivery. In fact, teaching, like preaching, is an art, partly natural, and partly acquired, and the faculty of teaching is, whether rightly or wrongly, seldom taken into account by those who elect Medical teachers and lecturers.

The consequence is that the evil has partly remedied itself by the self-appointment of private teachers in most of the schools, not only of Medicine, but of all other sciences. These gentlemen cultivate especially the art of teaching, and their success in their vocation depends entirely upon their success in this department. Under the name of private tutors and *coaches*, they are recognised by the English Universities, and in the Medical schools, under the same name, or sometimes as *grinders*, they are looked upon as a sort of necessary evil. The great fault of the *grinding system*, as it is called, is that it is resorted to by the idle class of students at the end of their career, in order to deceive or elude the vigilance of the examiners; but the same energy, and ability in teaching, exercised *all through the student's career*, would not only be permissible but also most desirable, as affording to the tyro in science the

assistance which he must necessarily require, and enabling him to comprehend with greater facility the discourses of the Professors, or the bed-side observations of the physicians and surgeons.

SUMMARY OF THE WEEK.

LEGISLATION ON THE "SOCIAL EVIL."

The remarks we made last week upon the proposed introduction into the legislature of a bill for the mitigation of the physical evils consequent upon prostitution, have been amply confirmed by published accounts, and speeches delivered by influential statesmen. At the anniversary dinner of the supporters of the Lock Hospital, held last Wednesday, Lord Clarence Paget, the Secretary to the Admiralty, publicly stated that a scheme had been submitted to the Government, which he was prepared to exhibit confidentially to gentlemen whose opinions were entitled to weight, and he believed that in the present session, some parliamentary remedy might be devised for the amelioration of the existing evils. We are ourselves acquainted with the principal features of the proposed scheme, but are not at present at liberty to make them known. It is sufficient to state, as we hinted last week, that punishment and sanitary segregation are among the objects aimed at in the proposed measure, in the case of those who wilfully and knowingly propagate disease. At the festival of the Lock Hospital, both the rank of the personages assembled, and the speeches delivered, gave the occasion a political significance, His Royal Highness the Commander-in-chief being in the chair, and the first Lord of the Admiralty, and the Secretary at War, besides Sir J. Y. Scarlett and Sir John Pakington being among the chief speakers. The Medical journals have also taken up the cue, and the political journals have already begun, by anticipation, to express their opinions on the proposed scheme, which is certain to give occasion to very warm discussion.

PROFESSOR REDWOOD ON THE PHARMACOPŒIA.

Professor Redwood delivered his second Lecture on the Pharmacopœia, at the Pharmaceutical Society, on Wednesday evening, before a crowded audience, which comprised many members of the Medical Profession. The discourse was altogether confined to points connected with pharmacy, after a brief introduction on the disputes which raged some centuries since between the Chemical School, headed by Basil Valentine and Paracelsus, and the followers of Galen, who employed in their medicines only the products supplied by nature. Dr. Redwood, in his remarks on the preparation of extracts, decoctions, tinctures, &c., noticed a rather ludicrous omission on the part of the compilers of the British Pharmacopœia, who, in their directions for making the tinctures, have, in several instances, omitted the very necessary process of "agitation," or "shaking." Now, as Mr. Puff tells the audience in the play of the 'Critic,' a shake of the head is a very significant matter, if only the actor shakes it as the author intended; and so in the manufacture of tinctures, the "shaking" is all essential, as without it the active principle of the drug lies dormant at the bottom of the vessel, and the supernatant spirit is unaffected and even uncoloured. In the next edition of the Pharmacopœia, it is therefore to be hoped that the compilers will not only order that the ingredients of *all* the tinctures are to be shaken together, but that the shaking shall be so efficient that the active principles may be thoroughly taken up by the spirit.

THE BETHNAL-GREEN GUARDIANS AGAIN.

The Guardians of the parish of Bethnal green have again come into collision with the superior authorities at Whitehall, in consequence of an inquest held upon a poor woman, who was said to have died partly from neglect. The verdict of the jury at the Coroner's Inquest inculpated the Bethnal-green Guardians, and called the attention of the Poor-law Board to the case; and in consequence, an Inspector was sent to take evidence. It appears that the deceased woman was attended by Dr. Moore, who, finding that she could not receive at home the necessary care and attention for her complaint, recommended her removal to the parish Infirmary. The relieving officer so far complied with this recommendation as to give an order for the *whole family* to be admitted into the workhouse, but this offer was declined on the part of the woman's husband, and the patient died at her own home. In this case, it must in all candour be admitted that the fault rests not only with the local authorities but with the law, and a most cruel, unjust, and oppressive law it undoubtedly is which, in the case of paupers seized with illness, orders their whole family into the workhouse, thus utterly breaking up their home, or takes the alternative of refusing relief altogether. Some of the newspapers, in commenting upon the facts, appear to be ignorant that the law is as we have stated it, and we ourselves, who have long been fully aware of its oppressive operation in this particular, are astonished that so harsh and cruel a practice should be tolerated. The parish workhouse is, to a certain extent, an infirmary for the sick, and to pauperise a whole family because one member of it is disabled by temporary illness, is as preposterous as it is cruel. In justice to Dr. Moore, and to correct certain misrepresentations which have been made, we print the following copy of Dr. Moore's certificate given in the case referred to, and which we think ought to have been complied with. We understand that this document, at the late investigation before the Poor-law Inspector, was "missing;" no doubt for a very good reason.

[COPY.]

SAINT MATTHEW, BETHNAL GREEN, MIDDLESEX.

Urgent.

18th day of February, 1864.

I hereby certify, that I have examined Sarah Dove, 6 Royston street, suffering from Diseased Lungs, and destitute of proper domestic comforts and attendance.

I advise she be *immediately* admitted into the Infirmary of the house.

(Signed) EDW. MOORE, Surgeon.

To Mr. Christey, Relieving Officer, Bethnal-green Workhouse, Bonner's fields.

THE LATE ALLEGED CASE OF POISONING AT HAYLE.

It will be recollected that Dr. Richard Millett, of Hayle,

in Cornwall, was accused of poisoning his brother, but was acquitted in consequence of the absence of all proof that he had committed such an offence, the death having in fact occurred from natural causes. The result was that Dr. Millett brought an action for illegal arrest against the parties who were said to have instigated the proceedings, and the case terminated during the last week in a verdict being given in favour of Dr. Millett, with 400*l.* damages. While congratulating Dr. Millett on this triumphant vindication of his character, we can only add our regret at the whole of the proceedings, which, we fear, originated in some family quarrel, the accuser and the accused in the criminal proceedings, and the plaintiff and defendant in the late action, being brothers-in-law.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 1ST, 1864.

MR. PARTRIDGE, PRESIDENT.

(Continued from page 191.)

ADDRESS.

The PRESIDENT commenced his address by advocating the expediency, for communities as well as for individuals, of an occasional retrospect of the past, with a view to the guidance of the future; to ascertain whether progress had been commensurate with opportunities, or whether there had not been seasons of indolence and inaction, the causes of which might be avoided in future. He reminded the meeting that the Medical and Chirurgical Society, like the "Royal," had its origin in a private meeting of a few scientific persons anxious for the promotion of knowledge, who held a preliminary meeting at the Freemasons' Tavern in May, 1805, and (after the organisation of the Society) a first ordinary meeting in the December of the same year. The Society's first place of meeting was in Verulam building, Gray's inn, then successively at two houses in Lincoln's-inn fields, where it continued until its removal to Berners street in 1835, in consequence (amongst other reasons) of its having been ascertained that a very large proportion of its resident fellows lived west of the former locality. The first President, in 1805, was Dr. Wm. Sanders, and the first volume of the 'Transactions' was published in 1809, under the presidency of Dr. Matthew Baillie. In 1812 an effectual application was made for a charter of incorporation. Its importance, however, was felt to be so essential to the status and stability of the Society, that the application was renewed, and a royal charter obtained in 1834. On this occasion the bye-laws and other regulations of the Society were revised and adjusted. During the period of removal, the Society, through the kind liberality of the then President (Dr. Elliotson), held its meetings at his house. The first meeting in Berners street was on the 10th of February, 1835. Since that time the Society had steadily advanced in reputation and usefulness, revising its laws from time to time, so as to adapt them to circumstances as occasion made it expedient, becoming more just and liberal in some of its regulations, adding largely to its magnificent library, and of late increasing its utility by the frequent publication of abstracts of its "Proceedings;" and finally, by instituting, from amongst its fellows, committees for the investigation of certain subjects of great general importance to the Profession, such as the "Committee on Suspended Animation," and that on "The Uses and Effects of Chloroform," the report of which is nearly completed. The success of the labours of the Society is attested by the publication of forty-six volumes of its 'Transactions,' forming a standard work of reference on the most important topics which have engaged the attention of the Profession during the last half century, and by the formation of one of the largest and best-managed circulating libraries of Medical books in the kingdom. Still (added the President) there remain great objects to accomplish, and foremost amongst them, the acquisition of a permanent residence, either in the shape of a freehold house, with some architectural pretensions as a public building, or of apartments in Burlington House, in association with other scientific bodies. This Society might fairly look for the favourable consideration of the Government in this matter from the advanced position which it holds amongst the other Medical Societies of this country, from its royal charter, and from the peculiar means which it possesses of conducting investigations of public utility upon Medical and sanitary subjects. The President then called the attention of the meeting to the very fine collection of Medical portraits and autographs now in possession of the Society, comprised—1st, in the Soden collection, recently presented by Mr. J. Soden, of Bath; and 2ndly, by the purchase of Mr. Squibb's collection, just sanctioned by the present general meeting; both together forming a collection unrivalled by any in the kingdom. Notice was also taken of the rapidly-forming series of photographs, commenced by Dr. H. G. Wright, of pathological specimens, and the Fellows were urged to contribute to these collections as opportunities offered. He then approached the painful subject of the losses sustained by the Society during the past year in the deaths of sixteen of its Fellows. This number, though double the average of the last ten years, was yet nearly equalled in two former years, and exceeded in two others of the same period (ten years.) The President gave a short memorial of each of these sixteen Fellows; but it would be impossible in this abstract to do more than allude very briefly to some of them. Amongst provincial Fellows, Mr. J. S. Soden, of Bath, Mr. Wm. J. Wickham, of Winchester, as hospital surgeons; Dr. Edward Stephens, of Manchester, as an anatomist and teacher; and Dr. Carter, of Deal, as a physician in extensive practice, were the most conspicuous. Amongst resident Fellows, Mr. Henry Ancel, as a gentleman largely engaged in general practice, a man of much ability as well as of laborious research and learning, as is shown by his works on Tuberculosis, on the Physiology and Pathology of the Blood, and by his unpublished treatise on Poisons of the Blood. On Mr. J. H. Green he passed a high eulogium, commenting on the great position which he held in the profession and in the governing bodies and professional societies of the country; upon his high, chivalric, and truly Christian character, his eloquence, and his extensive and varied learning. He thought Mr. Green's reputation would increase with time, and he alluded to the long and laborious years of study which he had given to the completion of a "System of Spiritual Philosophy," originated by Coleridge. It will interest every educated mind to know that there is a prospect of the speedy publication of this posthumous work, the result of Mr. Green's life labour Amongst the younger Fellows, the President especially noticed Dr. Edward R. Harvey, Registrar of St. George's Hospital, as one who, already distinguished by his researches in physiological chemistry, promised, had he lived, to have left a mark on his generation. Mr. Thos. Davis and Mr. H. C. Johnson were noticed as gentlemen who, each in his time, had enjoyed large practices, and who, without having contributed to the literature of their profession, were, nevertheless, remarkable as skilful surgeons, possessing in a wonderful degree the confidence of their patients. Finally, he deplored, as a loss to the scientific world, a foreign honorary Fellow, in the person of Professor Vrolik, of Amsterdam, whose works on the Chimpanzee, on Embryology, Teratology, &c. &c, are so universally known and esteemed, and whose reputation seemed hereditary. His noble museum, collected by his father and himself, was always open to the scientific foreigner, and his genial manner and knowledge of our language were particularly agreeable to our own travelling countrymen.

At the conclusion of the address, the best thanks of the meeting to the President were moved by Mr. FERGUSSON, seconded by Dr. WEIGG, and carried with acclamation.

It was also moved by Dr. C. J. B. WILLIAMS, seconded by Mr. DIXON, and carried unanimously,—"That the cordial

thanks of the society be given to the retiring Secretary, Dr. Sieveking, for his valuable and zealous services during the time he had been in office; and also to the retiring Members of Council—Dr. Hodgkin (Vice President), Dr. West (Vice President), Dr. Cotton, Dr. Gream, Dr. Geo. Johnson, Mr. Holt, and Mr. Holthouse."

Dr. Sieveking returned thanks for the honour done him.

The result of the ballot for Officers and Council for 1864-65 was then announced by the President as follows:—President: Mr. Partridge. Vice-Presidents: Dr. A. Farre, Dr. Basham, Mr. Hilton, and Mr. Fergusson. Treasurers: Dr. Pitman and Mr. J. Dixon. Secretaries: Dr. H. W. Fuller and Mr. John Birkett. Librarians: Dr. A. P. Stewart and Mr. Henry Lee. Other Members of Council: Dr. Goodfellow, Dr. Gull, Dr. W. Jenner, Dr. Meryon, Dr. Sibson, Mr. Holmes Coote, Mr. G. V. Ellis, Mr. C. H. Moore, Mr. E. Newton, and Mr. Toynbee.

March 8th, 1864.

On a new operation for obtaining union of an ununited fracture, with remarks on its application in certain cases of recent fracture.

By E. R. Bickersteth, F.R.C.S.

In bringing this subject before the attention of the Society, the author proposed to mention some cases that had occurred in his practice to show the successive steps by which he arrived at the process in question. He had frequently tried, in vain, friction, acupuncture, and subcutaneous division; and though resection of the ends of the bone had been successful in some instances, it was a proceeding involving a considerable risk to life. Dieffenbach's method had proved to be more successful; but this operation, though conducive to the formation of new bone, in no way provided for what was of paramount importance—viz., absolute immobility of the opening fragments. The large external wound and injury done to the soft parts in introducing the ivory pegs were also objections to this operation. Recognising the happy influence of Dieffenbach's plan of exciting ossific deposit, and at the same time feeling the importance of keeping the ends of the bone in a condition of absolute immobility, the author was induced to try a modification of the operation; and in the case of a man admitted under his care at the Liverpool Royal Infirmary, with an ununited fracture of the radius, he drilled a hole through the ends of both fragments, and passing a stout wire through it, secured the bone in perfect apposition. Union took place in seven or eight weeks, but on endeavouring to remove the wire, so much traction was necessary, that it caused the fracture again to be ununited. This difficulty of removing the wire induced the author to think of some other plan not open to this objection; and in the case of a man with an united fracture of the thigh, by means of a common Archimedian drill, he bored two holes in such directions that each passed obliquely through both ends of the fractured bone, and into each introduced a steel rod with a screw at the end. To do this it was necessary to make an incision three inches in length. Much constitutional disturbance followed, the wound suppurating freely. In ten weeks the splints were removed, but no union had taken place. The limb was then confined in gum-and-chalk bandages. Symptoms of pleuro-pneumonia came on, and he gradually sank. A post-mortem examination showed tubercular deposit in the ends of the bone and other parts of the body. There was no attempt at repair at the seat of fracture, except where the drills had pierced the bone, and here there was a deposit of new bone. This proceeding showed that it was quite feasible to fix the bone in the manner described, without exciting too much inflammatory action; and also that the steel rods caused the formation of new bone.

The next case was a fracture of the lower maxilla, where the bones had united in such a position as to render the patient a most unsightly object. As the incision that would be necessary in this instance, for the purpose both of putting the bone into proper position and removing the deformity of the soft parts, would not allow the use of external splints or supports, and as it was found impracticable to effect this object by fixing the teeth by an appliance within the mouth, it was absolutely necessary that some means should be devised by which the divided portions of the jaw could be securely fixed; and it occurred to the author that pegs or nails would answer the purpose, especially as he had already observed their presence caused so little inconvenience. Accordingly, at the operation, the plan just mentioned was carried out, and the apposition of the fractured portions was secured by means of two round-headed nails. They most effectually answered their purpose, and no external splint or bandage was required. The case did well, no undue action being set up. On the twenty-second day after the operation, one of the nails came away. The patient left the infirmary perfectly well, the jaw being firmly united in its proper position, and the deformity of the soft parts removed. One of the nails still remained in; and the last account states that its presence caused no inconvenience.

The third case recorded was one that presented many points in common with the one just narrated. No external incision was made, and ordinary drill heads were substituted for nails. The result was everything that the author could have wished.

These cases show how readily and with what good effect fractured bones may be fastened together. Surgeons have ever recognised the use of sutures with regard to the soft parts. Why should we not, in cases of difficulty arising from an inability to keep the surfaces in proper apposition, adopt the same plan with the bones? Might not this process be applicable in some cases where division of the tendo-Achilles is required, or where such an operation as sawing off the ends of the bone is indicated? From a consideration of the cases narrated, Mr. Bickersteth proposed to treat an ununited fracture by passing one or more drills through the broken ends of the bone in such a manner as to secure their perfect immobility, and without making any external wound beyond that caused by the entrance of the drill. The limb should then be secured by properly adjusted splints, and kept at perfect rest. After two or three weeks the drills may be removed, and water-dressing applied to the punctures. For several weeks after, it would, of course, be desirable to continue the use of the splints. In conclusion, the author begged to place upon record three cases of ununited fracture recently treated by his friend, Mr. Fletcher, on the plan that he (Mr. Bickersteth) had suggested, and in each the result had been most satisfactory.

Mr. Fergusson said that he scarcely remembered to have heard a paper of greater surgical interest than the one just read. It had the merit of bringing out much that was going on in the modern practice of surgery, and he thought the paper would lead to greater improvements in practice. Here was further proof, he continued, of the advantage of wire and metal in instances in which in former times we were loth to use such materials. He had had the impression that ivory pegs, being softer, would be less likely to do harm; but now the author had shown that metal might be safely used. And it had been shown, too, that the commoner metals were as useful as the rarer; that iron wire was as useful as silver wire. In the same way, cauterisation by an iron instrument was just as useful as by a gold or silver one. Dieffenbach had used the pegs of ivory to create irritation only, but the author had gone further, and fastened the bones together by pegs of iron. The author had shown that much might be done in desperate cases of ununited fracture. From hearing the cases related by the author, he should consider that the plan was safe, and that it ought to command attention. Mr. Fergusson said that he once saw Mr. Abernethy attempt to pass a seton between the ends of an ununited fracture. Failing to do so, he left a probe sticking in the wound between the ends of the bones. The result was good.

Mr. Holthouse thought the interest of the author's plan was not only in fastening the bone together, but in doing it subcutaneously. This was a great merit, and no doubt would lead to the adoption of the plan and to beneficial results in practice. Mr. Holthouse then gave the particulars of a case

of ununited fracture of the humerus under his care at the Westminster Hospital, in which he had adopted the novel proceeding of inserting the sharpened end of the lower fragment into the cancellous structure of the upper, thus imitating an impacted fracture. This plan, however, did not succeed. The case was, however, a complicated one, there being anchylosis of the elbow.

Mr. HOLMES COOTE rose to correct what he believed was a very general and erroneous impression as to the views of Dieffenbach. This surgeon used to cut down to the ends of the bones and pass in ivory pegs, with the hope of creating irritation; but, if he could do it easily, he used also to fasten the ends of the bone together. Mr. Coote thought that three classes of cases ought to be distinguished; first, those in which there was union in good time; second, those in which union was simply retarded; and third, those in which union could not be obtained, as the ends of the bones were in a state of fatty degeneration. In the third class no good results could be hoped for.

Mr. CURLING regarded the author's plan as ingenious, as a happy application of the modern treatment with metallic substances, and as calculated to be of great service, not only in ununited fractures, but also in compound and in complicated simple fractures, when it was difficult to keep the parts in position. He was struck with the remark in the paper that the author had met with numerous cases of ununited fracture Though Mr. Curling had been long attached to a large hospital where a great many fractures where admitted, he had seen only a few cases of ununited fracture, and all of them had been brought to the hospital in that condition, most of them being the result of accidents which had occurred at sea. The author, being surgeon to the principal hospital in the chief seaport city in this country, probably met with an unusual number of such cases. Mr. Curling had seen, however, many cases of delayed union, and mentioned two remarkable instances of the kind, one a double fracture of the thigh, which happened at sea seven months before, and might have been considered an ununited fracture, but which got firm in a plaster of Paris case. He called attention to a constitutional indisposition to ossific union, independent of general health, which was manifested in young people as well as in adults, and gave an instance in point of long delayed union in a fracture of the tibia in a girl.

Mr. BARWELL, while agreeing with what had fallen from Mr. Holmes Coote concerning the degenerated condition of bones, considered that such condition was the result, more frequently than the cause, of non-union. It was a law of animal nature that any organ losing its function should degenerate. Thus when a bone lost its power of support, the surrounding muscular pressure and other conditions of its healthy life, it would surely degenerate; but until that degeneration had reached a high point it might still be restored. A remarkable case had occurred to him lately, which would also show that in certain instances the admirable plan proposed by Mr. Bickersteth would be unavailing—as in cases where the non-union was produced by a large quantity of soft parts intruding between the fractured ends. The case alluded to was as follows: About eighteen months ago a man broke his arm about two inches and a half above the elbow. He was admitted into the Charing-cross Hospital. The fracture united well, and the man was discharged cured. The same night, however, he got very drunk, and broke his arm again, but took no notice of the circumstance, continuing drunk for about a fortnight. Two months ago he again entered the hospital with a broken arm. As Mr. Barwell had been for some time taking the duty of his colleague Mr. Canton, this case came, about a fortnight ago, under his observation, and he determined to operate. The upper and longer fragment was on the outer side, its lower end overlapping the head of the radius. The inner end of the lower fragment was half-way up the inner side of the arm. The movement to and fro of this portion was very considerable; but there was always a wide interval between the two bones, which was occupied constantly by the anterior brachial muscle, sometimes also by part of the biceps, and in certain positions it seemed as though the artery and nerve also got between the fragments. The man having been placed under the influence of chloroform, Mr. Barwell made an incision two inches long over the outer fragment, and turning out its end, sawed out a wedge-shaped piece, so as to leave an angular gap or notch in the end of the bone. The inner fragment lay so far away from the wound, and in such close proximity to the artery and nerve, that the greatest care was required in getting its end to protrude at the wound. This, however, was accomplished without untoward accident, and the end was cut into a wedge-shape, so as to fit with some degree of accuracy the internal in the upper fragment; traction was made upon the arm, and the two portions fitted together, and with the aid of a splint they retained perfect apposition. A singular condition of bone revealed itself during the operation—namely, that the periosteum on the upper fragment was loose, and could be slipped up off the bone as a man might turn up his shirt sleeves. This tissue was carefully replaced, yet, on account of this condition of bone, he (Mr. Barwell) could not but look to the issue of the case with some anxiety. The man had had as yet (ten days afterwards) no bad symptom.

Mr. C. H. MOORE thought the plan suggested would be valuable in some cases; but there would be some risk to life by tetanus and pyæmia.

Mr. HILTON said that, as a surgeon to a large hospital, he must add to the commendations of the other speakers his opinion that the paper was one of great interest, and that the plan was likely to be very useful when ordinary treatment had failed. He (Mr. Hilton) understood Mr. Holmes Coote to say that when there was fatty degeneration of the bone the ends never would or could unite; yet the author had related a case of cure by his plan, although at the operation the bone was so soft that a knife was passed through it.

OBSTETRICAL SOCIETY OF LONDON.

FEB. 4TH, 1864.

DR. GREENHALGH, V.P., in the Chair.

Mr. I. BAKER BROWN read a paper

ON FIBROUS TUMOURS OF THE UTERUS TREATED BY SURGICAL MEANS.

The author commenced by reminding the Society that on Dec. 7th, 1859, he had read a short paper on this subject, containing a case of fibrous tumour of the uterus treated successfully by surgical means. Also on March 6th, 1861, he had read a second paper on the same subject, giving six cases, four of which were cured, one was relieved, and one died. The object of the present paper was to confirm the practice previously advocated, by fourteen more cases, and at the same time to show that in most cases a very modified surgical treatment was sufficient; for whereas Mr. Brown had hitherto divided his operation into two parts—viz., first, preliminary incision of the os and cervix; and, secondly, gouging or breaking up the tumour,—he now finds that the first step will always arrest the hæmorrhage and the development of the tumour. In some cases the tumour decreases, and when small it will entirely disappear, more especially if of recent origin; and even when gouging is required, a much slighter operation is sufficient. Mr. Brown therefore now never uses "Harper's instrument," but only a pair of long-handled, blunt-pointed, curved scissors. The author entered minutely into the mode of operating, and laid great stress on carefully and thoroughly plugging the incisions and whole vagina with oiled lint after the operation, as on this point depended the chances of hæmorrhage, and exposure to air, and consequent hysteritis, and even peritonitis. Mr. Brown then read fourteen cases, occurring in the London Surgical Home, illustrative of his remark. Of these fourteen, ten were cured of the hæmorrhage by the incision of the os and cervix uteri alone, and one was relieved; in two only was it necessary to perform the second operation, both resulting in cure of the tumour; in six cases the tumour had either entirely disappeared or materially decreased after incision alone. Of the three deaths, one had occurred from peritonitis, resulting from exposure to cold and the restlessness of the patient; one from organic disease independent of the operation; and

one from pyæmia. Out of between twenty and thirty cases occurring in his private practice, the author stated that he had had one death, in a patient whose case was complicated with hæmatocele, and that in his public practice he had had as many more as were now given, with no more deaths.

The following practical conclusions were drawn :—

1. That the fact of the curability of these tumours is materially confirmed by these cases.

2. That it is not necessary in many cases to do more than incise the os and cervix, thereby much lessening the danger of the operation.

3. That the hæmorrhage is almost invariably arrested by the incision of the os and cervix.

4. That the cure of these fibrous or fibroid tumours by surgical means, without the danger of enucleation, is now firmly established, as proved by Dr. M'Clintock, Dr. Routh, Dr. Dawson, of Newcastle-upon-Tyne, as well as by himself (Mr. Brown).

Dr. Gervis wished to know from Mr. Brown whether the incisions he made in the sides of the cervix uteri were ever apt to reunite ; whether, if they did, the hæmorrhage recurred ; and whether, if they did not, the incised condition of the cervix in a patient who subsequently became pregnant in any way interfered with normal parturition.

Dr. Routh considered the paper as evidence of the advance of Medical science with respect to a disease many cases of which had been deemed incurable. He alluded to the process of enucleation recommended by Dr. Atlee, which he (Dr. Routh) regarded as too hazardous. It was known that many cases had ended fatally under the treatment, and he regretted they had not been published. Mr. Brown, however, had acted more nobly in publishing both his successful and unsuccessful cases. Dr. Routh considered that fibroid tumours required different treatment according to whether they were in or out of the cavity of the pelvis, whether the heart and lungs were pressed upon, or micturition impeded, or whether in either case excessive floodings occurred. In any case the tumour should not be meddled with unless vital functions were interfered with. Mr. Brown's operation could not be used in supra-pelvic cases because of the uncertainty of position and risk of wounding the peritoneum. In such cases he considered gastrotomy the best treatment, removing both ovaries also. In the pelvic fibroids, he agreed with the author that the tumours after bisection diminished, and he considered this an established point in practice. The opening of the cervix he believed not only checked the hæmorrhage, but enabled the tumour to be more easily got at ; it was, under the restrictions laid down by Mr. Brown, quite safe.

Dr. Greenhalgh considered the question of fibroid or fibrous tumours one of great importance, especially where the hæmorrhage endangered the life of the patient. In the great majority of cases he had found the best results from the use of bichloride of mercury or bromide of potassium. Still there was a certain limited class of cases in which medicines were of little avail, and it was in such that the division of the cervix uteri was attended with benefit. He had seen a few cases, and in these, although the hæmorrhage was considerably lessened, yet the size of the uterus was not much reduced. In those cases where pressure on surrounding structures had produced injurious effects, he had seen good results from pushing up the tumour above the brim.

Mr. Brown, in reply to Dr. Gervis, stated that care was taken to prevent the incisions in the os and cervix from uniting. The oiled lint, in the first instance, and the injections afterwards, generally prevented union ; but if any bands of lint were thrown out, he always broke them down with the finger. He had never seen a case in which the patient had been confined after the operation, but it was only reasonable to infer that parturition would be accelerated after these incisions ; for in the case of a primiparous woman, where the os is torn, the subsequent labours are always exceedingly quick. As to the *rationale* of the operation, Mr. Brown had avoided the question for fear of giving too wide a field for discussion. He thought the action was twofold. The tumours were of very low vitality, and the slightest interference with them stopped their growth. Thus, in the first place, the initiatory bloodvessels were cut through by incising the os and cervix ; and, secondly, the tumour was grasped more firmly by the contraction of the uterus, which always takes place after the os is incised ; and thus the tumour was confined, could not grow, and often died. He was obliged to Dr. Routh for alluding to the authenticity of his (Mr. Brown's) cases, as some doubt had on more than one occasion been thrown on the subject. He could only repeat that his practice at the London Surgical Home was open to every member of the profession. He had only given cases where severe hæmorrhage was present as the most urgent symptom, and in almost all the cases which came to him the patients had been previously treated without success.

After a few preliminary remarks, Thomas Bryant, F.R.C.S., gave the details of

TEN CASES OF OVARIOTOMY, SIX OF WHICH WERE SUCCESSFUL.

The following are their brief notes :—

Case 1. *Multilocular ovarian tumour ; ovariotomy ; death on fourth day.*—M. C——, aged thirty, married. Tumour discovered two years ; never been tapped. Ovariotomy on Dec. 5th, 1860 ; small incision ; pedicle, which was broad, fastened by double ligature ; wound brought together with pins. Opium freely given. Third day, vomiting, with tympanitis ; and death seventy-eight hours after the operation. Post-mortem : Peritonitis.

Case 2. *Unilocular ovarian tumour ; ovariotomy ; recovery.*—E. D——, aged thirty-two, married. Disease existed two years and a half ; had been tapped once. Ovariotomy on Oct 15th, 1862 ; small incision ; adhesions in front ; pedicle secured with clamp ; wound brought together with silver sutures. Uninterrupted recovery in one month. This patient has since been confined of a living female child.

Case 3. *Unilocular ovarian tumour ; ovariotomy ; recovery.*—A. S——, aged twenty-five, single. Disease four years ; tapped twice. Ovariotomy on March 20th, 1863 ; no adhesions ; small incision ; pedicle secured with clamp. Acute bronchitis. Perfect convalescence from the operation in one month. The patient subsequently died from pneumonia, two months after the operation.

Case 4. *Double ovarian disease ; ovariotomy ; death.*—E. C——, aged thirty-two, married. Disease two years ; tapped once. Ovariotomy on April 15th, 1863 ; extensive adhesions ; broad pedicle secured with three whipcord ligatures on left side, on right side with two. Collapse and death in twenty-two hours. Post-mortem : Peritonitis.

Case 5. *Semi-solid ovarian tumour ; ovariotomy ; death.*—J. P——, aged forty-four, married. Disease many years ; tapped once. Ovariotomy on July 25th, 1863 ; small incision ; broad pedicle secured with three whipcord ligatures. Death in thirty-seven hours from peritonitis.

Case 6. *Multilocular ovarian tumour ; ovariotomy ; recovery.*—L. W——, aged seventeen, single. Disease existed one year ; never been tapped. Ovariotomy on Sept. 8th, 1863 ; small incision ; no adhesions ; broad pedicle secured by three whipcord ligatures ; silver sutures to wound. Rapid convalescence.

Case 7. *Multilocular ovarian tumour ; ovariotomy ; death.*—H. D——, aged twenty-four, married. Disease three years ; tapped three times. Ovariotomy on Oct. 8th, 1863 ; small incision ; extensive adhesions ; broad pedicle requiring seven whipcord ligatures. Collapse and death in twenty-three hours. Post-mortem : Slight hæmorrhage into abdominal cavity.

Case 8. *Multilocular ovarian tumour ; ovariotomy ; recovery.*—H. B——, aged thirty-four, married. Disease one year ; tapped once. Ovariotomy on Oct. 8th, 1863 ; large incision ; no adhesions ; pedicle secured with three ligatures ; silver sutures to wound. Uninterrupted convalescence.

Case 9. *Multilocular ovarian tumour ; ovariotomy ; recovery.*—A. J——, aged thirty-seven, single. Disease one year ; never been tapped. Ovariotomy on Oct. 16th, 1863 ; large incision ; no adhesions ; clamp to pedicle ; silver sutures. Rapid recovery.

Case 10. *Multilocular ovarian disease ; ovariotomy ; recovery.*—S. C——, aged fifty ; married. Disease eighteen

months; tapped twice. Ovariotomy on Dec. 2nd, 1863; large incision; no adhesions; clamp to pedicle; silver sutures to wound. Rapid convalescence.

The author then passed on to make some general remarks on the operation. He confessed that in three of the cases which had been noticed the chances of securing a successful result from the operation were looked upon as being very slight, and that he should now in similar cases refuse to operate. He dwelt upon the propriety of being very careful in selecting cases, and expressed his belief that the surgeon had better err on the side of caution than on that of rashness. He considered that the best patient for the operation was the one who was in the best health, and that there was no special general preliminary treatment demanded which was not applicable to other operations. He enforced the necessity of isolating the patient, and of guarding her well from the contact of all who were not specially required for the treatment of her case. It was to the careful observance of this rule that he attributed his success. During the operation he preferred to place his patient in the half-sitting posture, as such was the most convenient for many reasons. He was indifferent to the length of the incision which he made, but had commenced always with the small incision, and increased it when any difficulty in the extraction of the tumour was experienced. He condemned the practice of exploring the abdominal cavity with the hand, in the search for adhesions, and advocated the practice of breaking them down as they manifested their presence during the operation, stating that by following this rule there would be but little necessity in the majority of cases of fingering the peritoneum.

LEGAL INTELLIGENCE.

WESTERN CIRCUIT, BODMIN.

NISI PRIUS COURT.—(*Before Mr. Baron* BRAMWELL *and a Special Jury.*)

MILLET V. EDMONDS.

Mr. Coleridge, Q.C., Mr. H. T. Cole, and Mr. Bullar were counsel for the plaintiff; and Mr. Karslake, Q.C., and Mr. Kingdon for the defendant.

The declaration alleged that the defendant had maliciously and without probable cause made an information before the Recorder, Mr. Tonkin, imputing to the defendant that he had maliciously administered poison to Jacob Curnow Millett, with intent to cause his death, and that he had so caused his death; that an application was made to the Secretary of State, for an order for the exhumation of the body; that the charge was pursued before the magistrates; that the case was heard for many days, and resulted in the discharge of the plaintiff.

This case, as may be recollected, created a great sensation at the early part of this year. The plaintiff was Richard Oke Millett, and was a member of the College of Surgeons. The defendant was also a surgeon residing in London, and had married the sister of the plaintiff. The action was brought to recover damages for a malicious prosecution, which charged that the plaintiff had caused the death by poison of his own brother Jacob Curnow Millett. The charge was made in the most deliberate manner, and was persisted in. The deceased resided with his brother, the plaintiff, at Penpoll, in this county. There had been an estrangement in the family, in consequence of the marriage of the plaintiff's sister with the defendant. Jacob Curnow Millett was of peculiar habits, had water on the brain, and was a man of very generous habits and strong religious feelings. Last year he had been failing, his eyesight had become impaired, and he complained much of his head, and could take but little exercise. In February, 1863, he altered his will, and bequeathed everything to the plaintiff. On the 30th of December, he partook of a very hearty dinner, and afterwards complained of feeling "sinking." The plaintiff gave him brandy, and he said he thought he felt better, but complained of cold. In the course of that evening it was evident that he had a seizure, and in a few hours he died. The plaintiff then sent for the coroner and the undertaker. An inquest was held, and a verdict was returned that the deceased had died from natural causes, and he was in due time buried; but in a short time the defendant applied to the Secretary of State for an order for the exhumation of the body. This was granted, and on the 22nd of January the plaintiff was arrested by two policemen on a charge that he had poisoned his brother; he was the next day taken before the magistrates at Hayle, where a large mob had collected. He was taken before the magistrates four times, but he was detained in custody all the time, as bail was refused; he was fourteen days in custody, but eventually he was discharged, and he then brought this action.

The plaintiff was examined at very great length, and he swore that there was not the slightest pretence for saying that he had anything to do with his brother's death or his uncle's death. His uncle was found dead in his bed. He found his father dead in his bed. His sister Jane had been found dead in her bed by his sister Caroline, who slept in the same room.

Dr. Taylor was called, and stated that he examined the intestines of the deceased, which were sent to him and he could not detect any symptom of poison nor the effect of any. The appearances were quite consistent with death having arisen from natural causes. The circumstances attending the death also led to the belief that death had arisen from natural causes. A copy of his report had been sent to the Secretary of State. He believed the deceased had died from pressure on the brain, from the serum found in the ventricle of the brain. The pain in the stomach of which the deceased had complained was to be accounted for by the hearty meal he had made. It was not a system of narcotic poisoning.

Several medical men were examined, who agreed in the view taken of the case by Dr. Taylor.

The defence was that in consequence of the sudden deaths of several members of the family, there were rumours in the neighbourhood which had at last reached the defendant, and that he had thought it incumbent on him to cause an investigation; that he had acted perfectly *bonâ-fide* in the matter and had not been actuated by any ill-will or malicious motive towards the plaintiff. In his examination the defendant stated that although at the time he considered there were sufficient grounds for the course he had adopted, yet he was now fully convinced of the plaintiff's innocence of the charge.

Mr. Baron Bramwell, in summing up, observed that it was impossible not to say that the plaintiff had been entirely acquitted of the charge which had been made against him He was acquitted on the evidence of some of the most eminent authorities in the world and on the statement of the defendant himself.

The jury, having retired, returned a verdict for the plaintiff—Damages, 400*l.*

The trial of Samuel Porter for the ill-treatment of a lunatic, took place at Bodmin last week, and resulted in a verdict of guilty, accompanied with a recommendation to mercy on the part of the jury, on the ground that they thought the defendant was not aware of the law. As the case was one involving some legal questions, the judge did not pass any sentence, and the defendant was discharged in the meantime, but under recognisances to appear when called upon.

OBITUARY.

THE DEATH OF MR. JOSEPH BOWMER, M.R.C.S.E.

We are sorry to record the death of this gentleman, which took place a few weeks since. Mr. Bowmer was very well-known to many of the Profession as the conductor of an agency office for the sale and transfer of practices and partnerships, and for other similar matters connected with the Medical Profession. Mr. Bowmer never enjoyed robust health, and indeed from early youth he was a victim to the complaint which finally carried him off in the thirty-fifth year of his age. The disease was asthma, caused by or complicated with emphysema, and this distressing af-

fection rendered his early studies in Medicine, and his subsequent career in practice, pursuits of extreme labour and difficulty. It was partly from this cause that he adopted the agency business in preference to the active duties of the Profession, but his disease became so much aggravated of late that he was obliged to resort to a warmer climate in search of relief. He returned to England in the spring of 1862, considerably improved in health, but the cold of last January was too much for his enfeebled constitution, and he sank in the early part of February. Mr. Bowmer was a most gentlemanly, honourable, and amiable man, and was highly esteemed by all those who came in contact with him. We are very sorry to add that he has left a widow and several young children wholly unprovided for, and the attempt to put forward one of the orphan boys as a candidate for a foundation scholarship in the Royal Medical Benevolent College, has failed from the circumstance that Mr. Bowmer did not practise in England. We understand that the business formerly conducted by Mr. Bowmer will be continued by Mr. Langley, and that the proceeds will be partly devoted to the family of the deceased gentleman.

Births, Marriages, and Deaths.

BIRTH.

HOOPER.—On the 11th ult., at Eastrop house, Basingstoke, the wife of Charles Hooper, M.R.C.S.E., of a son.

MARRIAGE.

WATSON—HOLDER.—On the 10th inst., at St. Barnabas, Kensington, by the Rev. Dr. Hessey, assisted by the Rev. J. McCaul, Charles George Watson, Esq., late Surgeon R.N., to Amy, only child of the late W. J. Holder, Esq., of Kensington.

DEATHS.

FROGLEY.—On the 15th inst., at Brighton, Ralph Allen Frogley, F.R.C.S.E., of Hounslow, aged 70.

PALEY.—On the 15th inst., at Seal, Sevenoaks, Kent, Anne, the wife of James Paley, M.R.C.S.

MEDICAL NEWS.

UNIVERSITY OF LONDON: MASTER IN SURGERY.—The following gentlemen have just passed the examination for the degree of Master in Surgery:—Richard Whitfield Hewlett, M.D., King's College; Walter Rivington, M.B., B.A., F.R.C.S. Eng. (Exam.), London Hospital; Rickard P. Burke Taaffe, M.B., F.R.C.S. Eng. (Exam.), St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having been elected Fellows at the previous meetings of the Council, were admitted as such on the 11th inst.:—William Bell, Rochester—date of membership, April 26, 1826; Frederick Disting Tothill, Charles street, St. James's square—date of membership, June 7, 1833; Charles Manners Smith, of H.M.'s Indian Army—date of membership, April 28, 1843; Charles Vines, Reading—date of membership, July 25, 1836.

LICENTIATES IN MIDWIFERY.—The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 16th inst.:—Jean Baptiste Blanchet, M.D., Quebec—date of membership, Jan. 26, 1864; Charles Edward Covey, Basingstoke—date of membership, May 6, 1863; Richard Thomas Freeman, Hatcham—date of membership, Jan. 27, 1864; James Smith Harris, St. John's wood—date of membership, July 31, 1863; Joseph Langhorn, Savile row—date of membership, Jan. 28, 1864; Alfred Monckton, L.S.A., Brenchley, Kent—date of membership, July 31, 1860; George Frederick Thomas, L.R.C.P., Canterbury, New Zealand—date of membership, Feb. 11, 1859; William Godfrey Watermeyer, Cape of Good Hope—date of membership, Nov. 20, 1863; William Samuel Wilson, Bayswater—date of membership, April 22, 1862.

POOR-LAW MEDICAL REFORM ASSOCIATION.—Mr. Griffin, Weymouth, begs us to state "that the Select Committee on Poor Relief have had three sittings, and it is understood that they have determined not to examine any further witnesses, and are now considering their report." Since March 9, the following subscriptions have been received by him in aid of the funds of the Association:—Dordge, T. G., Launceston, 5s.; Toynbee Joseph, 1*l.*; Ledgard, J. A., Wetherby, 5s.; Pound, G., Ash, 5s.; Pritchard, W., East Retford, 10s.; Barrett, J. T., Ashton-under-Lyne, 5s.; Harris, H. B., Watton post-mark, 2s. 8d.; W. S. E., 1s.; Mott, C., Chertsey, 10s.; Bury, G., Barnet, 10s.; Beurice, A., St. Thomas, 2s. 6d.; Roe, W., Barton-upon-Irwell, 1*l.*; Dorming, D., Barton-upon-Irwell, 1*l.*; Adge, H., Barton-upon-Irwell, 10s.; Fletcher, J. L., Barton-upon-Irwell, 10s.; Rogers, J., Strand, 10s.; Greenwood, T. F. Southwell, 2s. 6d.; Brown, F. J., Rochester, 1*l.* 1s.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAR. 23.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.

THURSDAY, MAR. 24.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.; Royal Institution, Prof. Marshall, "On Animal Life," 3 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

FRIDAY, MAR. 25.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, MAR. 26.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Huxley, "On the Structure and Classification of the Mammalia."

MONDAY, MAR. 28.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAR. 29.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On Diabetes, and its Successful Treatment. By J. M. Camplin, M.D., &c. Third Edition. London: John Churchill and Sons, New Burlington street.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

THE PHARMACEUTICAL SOCIETY.—The notice is inserted.

A SUBSCRIBER FROM THE BEGINNING.—The letter is inserted.

VIATOR.—The situation is procured only by interest with the Directors. The salary is about 200*l.* per annum.

JUVENIS.—The lectures at all the London Schools of Medicine commence in October, and registration takes place at the same time.

Dr. R. B.—In all probability the proceedings of the Medical Council will henceforth be made known to the Profession through the medium of the members of the Press. At present the results of the discussions are supplied, but not the discussions themselves.

A. B.—Ozone is very abundant near the sea, and probably has a favourable effect upon the health in many cases. Ozone is of allotropic oxygen, that is to say, oxygen under a different condition to that in which it usually exists.

Dr. J. L. EARLE's paper on Post-partum Hæmorrhage will be continued next week.

IATROS.—Chloroform is, chemically speaking, the terchloride of formyle, and the latter substance is the hypothetical base of formic acid, so called because it is found in ants, the Latin word for this insect being *formica*.

Dr. E. M.—We have received the newspaper, and have noticed the subject.

VIGIL.—The letter arrived too late this week, but shall be inserted in our next number. The other subject shall also be attended to.

DR. G. DE GORREQUER GRIFFITH's letter on "Missed Labour" shall appear next week.

PRIZE OF BRITISH MEDICAL ASSOCIATION.

Candidates for the ANNUAL PRIZE for 1864 are hereby reminded, that ESSAYS intended for competition must be sent to SIR CHARLES HASTINGS, Worcester, on or before the 11th of July next. The Essay for this year must be on PHYSIOLOGY; and the Writer may select his own subject in that department. The Prize consists of a Gold Medal, value Twenty Guineas, called the "HASTINGS MEDAL." The Essay must not be in the handwriting of the Author, nor must it exceed in length twenty-four pages of THE BRITISH MEDICAL JOURNAL. It must be forwarded, under cover, together with a sealed envelope bearing the motto of the Essay and containing the Author's name and address.

The Adjudicators will receive with most favour Essays showing the bearings of Physiology on Pathology and the Practice of Medicine.

The successful Essay is to be considered the property of the Association, and will be published in the Journal.

T. WATKIN WILLIAMS, Gen. Sec.

13 Newhall Street, Birmingham, March 14th, 1864.

Royal College of Physicians of LONDON.

TWO LECTURES ON THE LARYNGOSCOPE, will be delivered at the COLLEGE, PALL MALL EAST, by Dr. GEORGE JOHNSON, On Wednesday April 6th, and Friday, April 8th, at five o'clock P.M.

LECTURE I:—
THE METHOD OF USING THE INSTRUMENT, AND THE HISTORY OF ITS INVENTION.

LECTURE 2:—
ILLUSTRATIONS OF ITS VALUE IN THE DIAGNOSIS AND TREATMENT OF DISEASE,

(By order of the President.)

1864. W. COPNEY.

Royal College of Physicians of LONDON.

FIRST Part of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School, will commence on Tuesday, April 5th.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licencewill commence on Tuesday, April 12th.

Graduates in Medicine of a University recognised by the College, Licentiates of the Royal College of Physicians of Edinburgh, or of the King and Queen's College of Physicians in Ireland, and Registered Medical Practitioners qualified before January, 1864, are admitted to Examination, under special Bye-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials, required by the Bye-laws are to be left at the same time.

H. A. PITMAN, M.D. Registrar, Pallmall East.

University of St. Andrews.—The

Examination of Candidates for Degrees in Medicine will take place at St. Andrews on Thursday 28th, April next at 10 o'clock, A.M., and following day. Applications must be lodged on or before March 25th.

By order of the Senatus Academicus.

ALEXANDER MUIR, Secretary

14th, March.

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible or have altogether failed in effect. Imitations having arisen, be particular in the address.

Emperor Life and Fire Assurance

SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

Prize Medal, International, Exhibition, 1862.

F. R. Gustav Ernst, Orthopædic

and ANATOMICAL MACHINIST, Manufacturer of Surgical Instruments, Elastic Bandages, &c. &c

19 Calthorpe street, Gray's-inn road, W.C.

New American Preparations.—

W. TWINBERROW begs to inform the Medical Profession that he has had a large consignment (direct from Keith & Co., of New York) of ALL the MOST VALUABLE American Medicinal Preparations. Also—

EXT. CANAB. INDICA, direct from Calcutta.
PIERLLOT'S VALERIANATE of AMMONIA.
Manufacturer of the New Preparation of
PEPSINE with Wine—PEPSINA PORCI—Ditto VITULI.
PHARMACEUTICAL CHEMIST.
Edwards Street, Portman Square, and 59B Westbourne Grove, London.

Dr. Arnott's Hydrostatic or Float-

ING BEDS FOR INVALIDS. Also Air and Water Mattrasses. For prices and particulars, apply to EDWARD SPENCER and Co., 18 and 19 Billiter street, London. E.C.

Hedges & Butler, Wine Merchants,

&c., recommend and GUARANTEE the following WINES; Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s. and 30s.	per dozen.	
Good Hock	30s.	,, 36s.	,,
Sparkling Epernay Champagne, 36s.,	42s.	,, 48s.	,,
Good Dinner Sherry	24s.	,, 30s.	,,
Port	24s., 30s.	,, 36s.	,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820 at	120s	per dozen.
Vintage 1834	,, 108s.	,,
Vintage 1840	,, 84s.	,,
Vintage 1847	,, 72s.	,,

all of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s.; superior Sherry, 36s., 42s. 48s.,; Clarets of choice growths, 36s., 42s., 48s., 60s., 72s., 84s.: Hochheimer, Marcobrunner, Rudesheimer, Steinberg, Liebiraumilch, 60s.; Johannesberger and Steinberger, 72s., 84s., to 120s.; Brauneberger, Grunhausen, and Scharzberg, 48s., to 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontignac, Vermuth, Constantia, Lachrymæ Christi, Imperial Tokay, and other rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; very choice Cognac, vintage 1805 (which gained the first-class gold medal at the Paris Exhibition of 1855), 144s. per dozen. Foreign Liquers of every description. On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,
London, 155 Regent street, W.; and 30 King's road, Brighton.
(ORIGINALLY ESTABLISHED 1667.)

Fine Old Port, Twelve Years in

Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clarets, 14s., 18s., 24s. per dozen.

Bass' Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints; 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts; 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

"JUST IMPORTED—THE FINEST OF THIS SEASON."

Pale Newfoundland Cod-Liver

OIL and LIGHT-BROWN COD-LIVER OIL, from the Loffoden Islands.—These Oils are of superior qualities and can be confidently recommended to the Profession. The Pale Newfoundland Oil in one gallon bottle and basket included, 16s.: the Light-Brown bottle and basket included, 9s. per gallon. Post office Order to be made payable to THOMAS KEATING, 79 St. Paul's churchyard, London.

Weiss's Illustrated Catalogue, con-

taining nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first orignated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'TheLancet,' Sept 12th, 1863.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 180.)

The Signs and Symptoms.

A most essential point in post-partum hæmorrhage is to find out its existence at an early period. Suppose two cases of flooding, each commencing about five minutes after delivery, and, in fact, equal in every point, except that they were attended by different Medical men. In one case the attendant is a careful and intelligent practitioner; he knows very well that, the woman having been delivered, the most likely danger next to be apprehended is from an excessive loss of blood, and is, therefore, on the constant look out for its occurrence. The flooding no sooner begins than he finds it out, and takes immediate measures for its arrest. In the second case, the Medical attendant, belonging to that class who have a great dislike to midwifery, and a contempt for its dangers, takes no notice of his patient for twenty minutes after delivery. He then finds that she is flooding, and commences the proper treatment fifteen minutes after he ought to have done. The hæmorrhage in the first case will have been probably arrested before it has been found out in the other, and how much more satisfactory a state she will be left in than the patient of the indifferent and negligent Medical man!

I have not the slightest doubt in my own mind that several of the cases of hæmorrhage after delivery, which we read or hear of as having terminated fatally, would have ended satisfactorily, had the attendant taken the complication in hand at an early period of its existence.

Fortunately, we have many and simple means of finding out whether a woman is, or is not, losing more blood than is proper. Sometimes the first indication is the increasing rapidity of the pulse. After labour, the pulse generally decreases in frequency, and if we should find it does not fall, or having decreased, it gradually becomes more rapid, we may be sure that the loss of blood is telling unfavourably upon the system. In the majority of cases it is an excellent sign of an undue loss of blood going on. I do not agree with some who think it is sometimes a premonitory symptom of flooding, a forerunner of the coming evil; but that in all cases, whenever a rapid pulse after delivery is connected at all with hæmorrhage, the undue loss of blood is actually going on at the time. A rapid pulse after labour may be due to other causes besides hæmorrhage, for instance, exhaustion, or inflammatory affection of the uterus. The latter is very rare soon after labour, and in exhaustion the pulse is generally frequent, before as well as after delivery; whereas in post-partum hæmorrhage, unless it follows the birth of the child immediately, the pulse first falls, and then gradually increases in frequency. It must be borne in mind that hæmorrhage often occurs after laborious and exhaustive labours, and in such cases, we require the assistance of other signs to enable us to tell how much of the rapidity of the pulse is due to exhaustion, and how much to the loss of blood. Whatever may be the cause, it is our duty to institute an inquiry, and examine the state of the uterus, and the amount of loss externally. I met with the following interesting and rare cause of rapidity of the pulse soon after labour. The pulse was 130. I examined carefully the condition of the uterus externally, and the amount of loss, but the former was well contracted, and the latter was less than usual. The patient did not feel exhausted, and there was certainly no reason why she should be, as the labour had been only lingering, and not laborious. The pulse kept up to 130, neither more nor less for two days; when on the third morning, I found that a large crop of herpes labialis had appeared around the right angle of the lips, and that the pulse had gone down to 100, showing very satisfactorily the cause of its previous abnormal frequency, and at once dispelling my naturally excited fears.

Although in the greater number of instances, an increasing rapidity of pulse within a few hours after delivery indicates an undue loss of blood, we may meet (certainly very rarely) with dangerous cases of flooding, in which the pulse is not affected at all. I have met with two instances in which both the women were blanched from the large amount of blood lost, and yet the pulse was never more than 80 for the first forty-eight hours. Probably in such cases, the hæmorrhage generally occurs in the form of a continual draining, and the heart accommodates itself to the gradual loss.

A dilated pupil is another good sign of an undue loss of blood going on, and it occurs very early. It may be due to pre-existing anæmia or other causes, but its presence ought at once to excite our suspicions. Another symptom is hurried breathing. During the last stage of labour the patient generally breathes more rapidly, that is due to the unusual exertion and excitement she is labouring under, then, as soon as the delivery is effected, the respiration, unless the patient is very much exhausted, or is suffering from a serious chest affection, calms down almost suddenly. When flooding is going on, the increasing shallowness of the breathing cannot well escape the attention of a watchful practitioner.

We should ask the patient every now and then whether she is losing much; we ought never to depend upon her answer alone, because very often a woman has not a clear notion as to what should be considered a large loss of blood. I have frequently asked women if they were losing much, and received in answer "not more than usual," "not more than is proper." On further examination, however, flooding was found actually to be going on; while, in other instances, women have told me that they were losing a great deal, when both the napkin which had been applied to the vulva and ocular examination testified to the contrary. In some cases we are first made aware of the existence of flooding by the patient expressing a feeling of faintness, or that she is "losing a great deal;" while in others we discover the nature of the case by the noise caused by the expulsion of clots, or the splashing of blood from the vulva into the bed or on the floor; in more rare instances, we hear a gurgling sound produced by the uterus first filling with blood, then contracting and expelling its contents.

Another excellent way of ascertaining the amount of loss is by applying a napkin to the vulva. If we should find it in five minutes saturated with blood, we know that the patient could not go on long losing at the same rate without getting into danger, and three napkins wet through in less than half an hour, clearly indicate that the patient is losing too much. There are two or three fallacies which we must remember when judging the amount of loss from the appearance of the napkin. After the delivery of the placenta, the patient sometimes lies in a mixture consisting of blood and liquor amnii; if we were to apply the napkin to the vulva before the nurse had wiped away the mess which surrounds the left buttock and thigh, the napkin would soon become saturated with the fluid previously expelled, and deceive us with the idea that the patient is flooding when she is not. Then, again, if the napkin does not touch the vulva and thigh, an excessive draining may go on without the diaper being much if at all soiled. For this reason the surgeon should always apply the napkin himself. The first napkins ought to be large, so as not only to cover the vulva, but also a large portion of the neighbouring parts.

The most certain testimony is of course ocular examination, and it should always be made if we suspect flooding. There is no necessity for direct exposure. Compress the uterus with the left hand, and lift up the clothes with the right just sufficient to show the back of the left thigh (I am taking for granted that the patient is lying on her left side), all the blood which escapes will run down that leg.

We may be put off our guard even when an ocular examination has been made. If the patient should happen to lie rather forwards towards the belly, the blood, instead of running over the lowermost thigh, will be guided along the groove between the labiæ and nymphæ, forwards over the pubes and abdomen. In such a case, the patient may be quite dry behind while the clothes in front are saturated with blood. Again, if she lies too much towards her back, the blood will gravitate backwards along the groove between the buttocks up the back, and so escape our observation. Whenever we wish, therefore, to ascertain the amount of loss, we should keep the patient perfectly on her side, if anything, lying rather backwards than forwards.

In a few cases of internal hæmorrhage, the uterus fills with blood without much escaping outwardly; but generally, when a large quantity of blood collects in the cavity of the uterus, it is attended by an undue flow externally.

We may sometimes erroneously think that a woman is flooding from the presence of a continual draining, the draining being merely due to the presence of a large clot in the vagina. Press the uterus with the left hand, and turn out the clots with one or two fingers of the right. The draining will of course then cease. By one or other of these means, we can readily find out whether the complication exists or not.

If the loss should go on notwithstanding our attempts to arrest it, the pulse increases in frequency, and becomes more and more feeble; the face and lips gradually lose every vestige of colour; faintings occur at short intervals; the patient frequently sighs deeply and yawns; expresses an uncontrollable desire to sleep, and will drop asleep constantly unless kept awake. While flooding is going on the patient should never be allowed to indulge these feelings—first, because when she is asleep we cannot be certain as to how she is going on; she may be in a fainting fit, and not merely sleeping. 2nd. The temporary sleep of life in these cases, as in those brought on by intense cold, may pass quietly into the long sleep of death. As the loss of the vital fluid progresses, all the above symptoms are intensified, and new ones supervene. The face becomes bedewed with cold perspiration, and the extremities lose their natural heat. The patient says she cannot see, quietly asks for her husband and children, and sinks into a state of apathy, not caring whether she lives or dies. The faintings occur not only more frequently, but are more prolonged, and during the insensible state the jaws are usually spasmodically closed, which is very annoying, as it causes a difficulty in administering the necessary restoratives. When the teeth are tightly clenched, the brandy must be poured through an aperture produced by the loss of one of the teeth, or if they are perfect, through a natural space which exists behind the wisdom teeth.

Vomiting is a symptom which only occurs after the loss of blood has been very great. In the instances in which I have observed vomiting, the patients not only have been flooding for some time, but have imbibed a large quantity of brandy and a dose or two of ergot. May not the vomiting be due in some cases to the mixture of brandy and ergot with its gritty particles? This symptom is very alarming to a young hand; *a priori*, one would think that an attack of vomiting would be most serious in its results to a woman almost brought to death's door by hæmorrhage; increasing the depression, and the loss of blood. Fortunately, on the contrary, when moderate, it has a very beneficial effect. Vomiting excites the uterus to contract, and rallies the patient. Whether it would be prudent to bring on vomiting by giving emetics, requires further investigation. We possess so many other remedies, that it would seldom be necessary to have recourse to vomiting artificially induced.

In the most dangerous cases, the patient asks for air, complains of a sense of tightness or constriction of the chest, says she cannot breathe, and becomes very restless. A fatal termination is preceded either by prolonged fainting, or a few convulsive movements. About two years ago a surgeon asked me to accompany him to visit a woman who was said to be flooding. She had been confined a week. On our arrival we found her dead. I mention this incident because it affords me an opportunity of describing the position in which she lay. It was so characteristic of the great restlessness preceding death from flooding. Her legs were widely separated, one arm was tossed in one direction, the other in another, and the body lay in an oblique direction across the bed.

(To be continued.)

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

NOTES ON SOME OF THE CASES UNDER THE CARE OF

Dr. Greenhalgh, Physician-Accoucheur to the Hospital.

The last patient we visited was one who had an enormous tumour in the abdomen, which caused that part of the body to measure in its circumference about 45 or 50 inches. The skin was, however, not very tense, and was completely unadherent to the tumour, a fact ascertained by passing the hand over the entire surface of the abdomen, and in all directions moving the integument, as well as by making the patient, when she lay in the semi-erect posture, take a deep inspiration. This latter act on the part of the woman showed the skin over the tumour to be quite non-adherent, inasmuch as it freely moved according to the respiration, nor was there any retraction of the umbilicus.

The abdominal veins were distinctly evident as they coursed through the thinned skin.

There was marked dulness over the centre of the tumour; on the right side there was very distinct tympanitis, while on the left the percussion elicited an obscurely clear or slightly tympanitic sound. Fluctuation was easily detected, not that localised fluctuation that would exist were the tumour caused by a multilocular ovarian cyst, but the diffused form; that is, the stroke of the fingers on one side of the tumour agitating the contents, caused that stroke to be felt by the other hand placed on the opposite side; the distinct series of waves from the one side to the opposite produced by the concussion, demonstrated the existence of fluid, and also that it was not contained in separate compartments.

The tumour could be sufficiently distinctly defined to pronounce the case to be not one of ascites. It was, from the history given by the woman, and also from the symptoms now present, clearly a case of ovarian or encysted dropsy; but it was impossible at this stage of the disease to decide which was the affected gland.

This disease develops itself most commonly in women of a scrofulous habit, and of those we meet it more frequently in the married, especially if they have borne children; at the climacteric period we not infrequently meet with it. It may not, however, have originated at this period, but merely have taken on increased activity, and have become developed with a rapidity induced by the changes in the entire generative system. It is rare in the early years of life.

The development of the tumour—always slow—may be divided into stages—the first or pelvic, the second or abdominal. It sometimes is a long period before the diseased ovary may leave its berth in the pelvis; while occupying this position it will give rise to symptoms referrible either to

reflex irritation, to mechanical pressure, or to the morbid conditions and processes in the ovary itself. There are uneasiness and a sense of dragging at the loins, and of weight in the pelvis; in some instances there is a feeling of distension, or of mere fulness in the same region. The menstrual function becomes deranged, and the discharge will in some way or other deviate from its healthy conditions; sometimes it will be altogether checked, morning sickness will set in, and the breasts will enlarge, and become painful, as though the woman were pregnant; in some cases there may be even a secretion of milk. These changes take place especially, according to M. Robert, in that breast which corresponds to the diseased ovary. So far may the idea of pregnancy obtain possession of the patient's mind, that she will even imagine herself to be conscious of the fœtal movements in the womb.

Difficulty in emptying the bladder and bowels will present itself in this stage of the ovarian enlargement, and the woman will be perhaps troubled with piles; sometimes the bladder can only be relieved by means of the catheter. All these last mentioned symptoms will be aggravated and rendered more immediately urgent, if the ovary—premising it to be the seat of cystic disease—should have fallen between the bladder and rectum, and there have become impacted.

By an examination per rectum we can detect the tumour, get beyond it, and bring the finger in contact with the neck of the womb. This manœuvre will assist us materially in our diagnosis, and enable us to distinguish the lesion from an ovary simply prolapsed or enlarged, or from a displacement backwards of the uterus. Vaginal exploration will also make known to us the condition of the os, the cervix, and the entire of the uterus, which may be turned by the tumour away from its proper berth, or being not at all disturbed, may preserve its normal situation.

In the second or abdominal stage the symptoms will be somewhat varied, and the following will be observed:—There will be a defined tumour in the iliac region corresponding to the diseased ovary; the compressing force will in a great measure be removed, so that there will not be that obstinate constipation; in some instances in this stage the bowels will be able to act naturally, the bladder will no longer be affected with retention of its contents, the very opposite condition existing; sometimes the flow of urine will be very much diminished, or even altogether checked by the tumour coming to press upon the bladder. The legs will become œdematous, and the rectal veins will be distended, owing to the pressure exercised by the cystic mass; the different abdominal viscera will be displaced, and as the growth enlarges the thoracic will become functionally deranged, and may even participate in the general alteration of position,—dyspepsia, difficulty in respiration, palpitations will hence be attendant.

At this period of the disease the uterus will be drawn upwards by the ascending ovary, the vaginal canal will be elongated and the mouth of the womb will be found to be higher up than it is naturally; as however the complaint advances the uterus will be depressed, owing to the gravitation of the tumour.

The health continues for some time to be but little affected, until the morbid conditions or processes in the ovary itself come to exercise a prejudicial influence.

The morbid processes, to which allusion is made, are inflammation of the sac, suppuration and its attendant fever; the fever in this form of dropsy is not, however, always of the hectic type, it may in some instances or in certain conditions of the sac be distinctly dynamic, in others as distinctly adynamic; it may even partake somewhat of an intermittent character.

If the patient remain unrelieved, all the above symptoms will become aggravated, the palpitations will be increased, the heart's action irregular and entirely deranged, the breathing greatly interfered with, the tension of the abdomen so excessive as to very much thin the parietes, and to induce so great a degree of tenderness of them, that they can scarcely tolerate even the weight of the bed clothes, the patient rapidly emaciates and dies of exhaustion.

ARMY REPORTS.

No. 3.

STATISTICAL, SANITARY, AND MEDICAL REPORTS FOR THE YEAR 1861.

ISSUED BY THE ARMY MEDICAL DEPARTMENT, OCTOBER, 1863. Pp. 552.

Report on the Gun-shot and Sabre Wounds of Invalids sent to Fort Pitt during the Years 1860 *and* 1861. By Thomas Longmore, Esq., Deputy-Inspector General, and Professor of Military Surgery to the Army Medical School. Pp. 30.

(Continued from page 199.)

In Mr. Longmore's pamphlet, at page 10, we find mentioned, under Class 8, "Wounds of the Upper Extremities," that in one instance only was the discharge of the patient due to non-union of a fractured bone. We can somewhat understand this, as we have recently heard of an instance of a man continuing to do his duty until ordered to rifle practice, when it was found that he could not sustain his musket at the level; on examination by the surgeon, all the tissues around the right elbow-joint were found thickened and condensed, and an indistinct crepitus was heard. It appears that while on foreign service the humerus was fractured, and having united badly, was rebroken, but had never re-united. The thickening of the tissues evidently acted as a natural and effective splint. Strange to say, this man was also blind of an eye. His object, we suppose, in serving under such circumstances must have been to gain service time. His pluck must have been good, and the surgeon had to deal with the converse from what he ordinarily meets—namely, a reticence in order to remain in the service. In a case, page 11, after amputation of the little finger, "the pain was so great, and the irritation so constant, by day and night, slight as its origin appeared to be, that the patient was greatly reduced in general health. The cicatrix was opened, and a portion of it, suspected to be the part in which the nerve was involved, from its special tenderness, was excised. The result was most satisfactory, for total relief from the pain followed. On examination by the microscope, it was ascertained that the part excised consisted chiefly of nerve-fibre enclosed in cicatricial tissue." This may guide us in cases of severe and intractable neuralgia, to excise a portion of the nerve; hitherto, a simple division, generally unavailing, has been practised.

We observe that no cases of wounds of the abdomen passed through Fort Pitt, showing their deadly nature, for all had died.

Under Class 4, "Wounds of the Chest," there are several very interesting cases recorded, and we have to express our satisfaction at seeing that the mode of treatment advocated by Dr. Patrick Fraser is followed, and that in exceptional cases only is venesection practised; also that the signs of lung wound are now better distinguished; although we perceive that there is still a tendency to put down all doubtful chest cases, as those of lung wound. We trace the beneficial influence of Dr. Fraser's opinions in the following remarks: Page 5, "The frequency with which non-penetrating gun-shot wounds of the chest are accompanied with hæmoptysis is well known." Again, at page 6, "Hæmoptysis, dyspnœa, supervention of pleuritis, are well known to be frequent accompaniments of gun-shot wounds of the chest, when no penetration deeper than the external parietes has occurred, and more especially because observation leads to the belief that gun-shot injuries to the chest *without penetration* are by no means unfrequently reported to be *penetrating* wounds, from the presence of symptoms which are really common, under certain circumstances, to both classes of injuries."

Now, these and similar observations are put forth as having been well known and accepted by the Profession.

whereas it was only in 1859 that Dr. Fraser drew attention to the vague ideas which previously prevailed as to the symptoms and treatment of lung wounds.

On the other hand, a clear ignorance of the import of Dr. Fraser's views is displayed at page 7. "The patient, Ensign ——, lived for twelve days after the injury; and chiefly from the absence of the symptoms of hæmoptysis, and of any marked dyspnœa, a Medical officer of experience was led into the mistake of assuring the colonel commanding this officer's regiment, that the lung had escaped from being wounded." This officer shortly died. If John Hunter's very odd suggestion that, in order to be prepared for the possibility of a soldier having one lung wounded, he should learn to breathe with one lung only, could be carried out, the absence of dyspnœa would be still less a proof of lung wound! The third case, at page 5, was sent home as having been a clear case of lung wound, but it was decided at Fort Pitt, and we think rightly, from the evidence given, "that the ball had made a circuit external to the pleural cavity, and had not passed through the lung." We demur to the following remark appended to the foregoing case: "Had there happened to have been forcible expulsion of air at each expiration, which is so strongly marked a symptom in a perforating wound communicating with a bronchus, a different diagnosis would have been necessary."

We do not see how this forcible expulsion of air on expiration can indicate a wound of a bronchus, unless the wounded bronchus be in immediate apposition with the external wound shortly after its infliction, a very unlikely, if not impossible, anatomical condition, or unless from adherent pleural walls, the effects of previous inflammatory action. These mistakes are the consequences of holding an opinion that the air, forced through the external wound on expiration, issues from a wound in the substance of the lung, whereas it is the air forced out from the pleural cavity by the contracting chest parietes, and this happens when there is no wound of the lung; for this we have experiment as well as actual illustration in favour of our view.

An opening was made into the right pleural cavity of a dog, the external air was observed to pass freely inwards upon inspiration and outwards upon expiration. The lungs were found entire, no opening into a bronchus or any portion of the lung tissue. In a soldier, with an apparent wound of the lung, the air gurgled with a loud sound through the wound on expiration; this symptom ceased in four days, and the man perfectly recovered in a month, thereby proving that the lung substance had not been wounded.

We could continue our selections from the "Reports," the "Statistical," by Dr. Balfour; "Sanitary," by Dr. Logan; and the "Medical," by Dr. Mapleton; and the several isolated papers, one especially by Dr. Lawson, on "The Influence of Pandemic Causes in the Production of Fevers," with great interest to ourselves and benefit to our readers, but our space demands a stop. We would say, in conclusion, that in future "Reports," especially on special subjects, such as Mr. Longmore's, a recognition of former writers on similar subjects, even although by the "Civil Element," would not be undeserved or ungraceful.

PROSTITUTION IN NEW YORK.—The "social evil" flourishes in New York as in no other large city of the world. The miserable creatures who ply their trade have not the slightest legal restraint. When so thoroughly diseased as to be compelled to seek medical relief, they apply to the Alms-House, where they remain until relieved, and then return to their old haunts. Every form of venereal disease may be found among these persons, which they propagate far and wide without hindrance. During the year 1862 5,818 females of this class were admitted to the Island Hospital. The greatest problem presented to our philanthropic citizens is the restraint and proper control of this great evil. As yet no one in our community has had the courage to attempt to obtain the necessary legislation. But relief must eventually be sought from the Legislature; and we hope the Prison Association, or some similar body, will move in the matter.—'American Medical Times.'

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF
H. LETHEBY, M.B., M.A., PH.D., &c.,
FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. VIII.

ACIDUM SULPHURICUM.—The sulphuric acid of the London Pharmacopœia was the oil of vitriol of commerce. It had a sp. gr. of 1·843, and all its characters corresponded to the best kind of commercial oil of vitriol. The sulphuric acid of the British Pharmacopœia is not the acid of commerce; but is to be prepared from that substance by a special process. It is described in the Materia Medica as having a specific gravity 1·846; oil of vitriol, rarely, if ever, reaches that density. It is also represented by the Chemical Formula, SO_3HO; this formula, however, strictly speaking, belongs to an acid having a density 1·848; there is, therefore, to this extent, a discrepancy in the description given. The change which has been made in the strength of this acid must be regarded as unnecessary; and the process which is given for preparing the acid, will, we fear, prove to be impracticable.

The impurities commonly present in oil of vitriol are sulphate of lead, nitrous or nitric acid, and arsenic. Occasionally, also bisulphate of potash or soda is fraudulently introduced, to increase the density of the acid. Commercial sulphuric acid, also varies somewhat in strength, arising in some cases from its tendency to attract moisture from the air. The sulphate of lead, which is invariably contained in oil of vitriol, is derived from the leaden pans in which the acid is concentrated. It is precipitated when the acid is diluted with water; its presence is, therefore, readily recognised. The oxygen compounds of nitrogen come from the chambers in which the acid is produced. Their presence may be detected by putting some of the acid into a test tube, and pouring over its surface a solution of protosulphate of iron; a dark ring is formed where the two liquids come into contact. With pure acid, of course no change occurs. The quantity of arsenic in oil of vitriol varies very greatly. It is chiefly derived from the iron pyrites which is burnt for the production of the acid. Some kinds of pyrites contain a very large amount of arsenic; and when sulphuric acid is made from this source, it is largely contaminated. Even the best Sicilian sulphur, however, generally contains a minute quantity of arsenic; and the acid made from it consequently possesses a slight trace. Mr. Bloxam, the Professor of Practical Chemistry, at King's College, carefully investigated this subject some time back, and he found it impossible to obtain in commerce a single sample of sulphuric acid absolutely free from this important contamination, even when specially manufactured from the best materials. Nevertheless, it is always easy to find sulphuric acid sufficiently pure for all medicinal purposes; but, as the proportion of arsenic is so liable to varia-

tion, it is important that the acid should be examined before adopting it for use. It is also desirable, however, to employ such a means of testing as shall not reach very minute traces, or, at all events, shall enable the operator to discriminate readily between much or very little. This the London Pharmacopœia satisfactorily accomplished by directing that the acid, when diluted with twelve parts of water, should yield no yellow precipitate after treatment with sulphuretted hydrogen.

The sulphuric acid of the British Pharmacopœia is to be obtained by distilling the oil of vitriol of commerce with a little sulphate of ammonia. But the commercial acid, selected for this purpose must not contain arsenic. Before it is submitted to this process, it must stand the following test:—"When the acid, mixed with six times its volume of distilled water, is placed in contact with pure zinc, and the hydrogen evolved is ignited as it escapes from the capillary extremity of a glass tube, if a dark stain is formed on a piece of porcelain, held low down on the flame, the acid contains arsenic and is to be rejected." This test is an exceedingly rigid one; far more severe and less practical than the one which was given by the London Pharmacopœia. If carefully and properly applied, it will reveal such small quantities of arsenic, that it will be somewhat difficult to find a sample of commercial oil of vitriol which will comply with it. But it is not so easy to apply the test thus ordered by the British Pharmacopœia. Pure zinc is to be employed; now it is almost as difficult to procure zinc free from arsenic as it is to obtain sulphuric acid free from arsenic. The operator will, therefore, naturally turn to the Pharmacopœia to see how he is to determine the purity of his zinc, and he will find the following test given:—"The hydrogen gas evolved when the metal dissolves in dilute pure sulphuric acid does not blacken a piece of paper moistened with a solution of acetate of lead; and when ignited gives no dark stain to the lid of a porcelain crucible, held low down in the flame." To determine the purity of his zinc, he must have pure sulphuric acid, which must be previously examined by means of pure zinc!

Having obtained sulphuric acid of commerce, which will give no indication of arsenic by Marsh's test, it is to be distilled. Twelve fluid ounces of it are to be put into a plain retort with a quarter of an ounce of powdered sulphate of ammonia, and a few slips of platinum foil. The upper part of the retort being covered with a sheet iron hood, one-tenth of the acid is to be distilled over and rejected. The distillation is then to be continued, and the product preserved until only a fluid ounce remains behind. The sulphate of ammonia reacts on the nitrous and nitric acids, converting them into permanent gases, which escape. The sulphate of lead also remains behind in the retort. The product is, therefore, freed from these two impurities; moreover, by the rejection of the first portion of the distillate, the acid is strengthened. This process is both difficult and dangerous. The boiling point of oil of vitriol is very high, and its adhesion to glass is very great; consequently, when an attempt is made to boil it in a glass retort, the bumping is so violent as either to fracture the retort and scatter the acid about, or else to project the acid bodily over into the receiver. The slips of platinum foil to some extent moderate this percussive action at the commencement of the process, but they are of little avail towards the end. Surely then such a troublesome operation should not be undertaken unless some solid advantage is gained by it? Yet it can hardly be said that the sulphuric acid of the British Pharmacopœia is better in any respect for use in medicine than the acid hitherto employed. If sulphuric acid can be found in commerce free from arsenic, it can also be found sufficiently free from nitrous acid. The sulphate of lead can be readily removed by diluting the acid. There only remains then the increased strength; but we know of no purpose in medicine or pharmacy for which strong acid is required. Moreover, the sulphuric acid of the British Pharmacopœia is only some two or three per cent. stronger than the acid of commerce.

Sulphuric acid forms three definite hydrates. A Monohydrate, $SO_3\ HO$, a Bihydrate, $SO_3\ 2\ HO$, and a Terhydrate, $SO_3\ 3\ HO$. The Monohydrate has, according to Dr. Ure, a sp. gr. 1. 8485. It boils at 620 deg. F., and freezes at many degrees below the zero of Fahrenheit's scale. The Bihydrate crystallises at 45 deg. F., that is to say, 13 deg. above the freezing point of water. It is in the proportion of the Terhydrate, that sulphuric acid and water undergo the greatest condensation, or reduction of volume in combining.

ACIDUM SULPHURICUM AROMATICUM.—This prepartion was contained in the Edinburgh and Dublin Pharmacopœias. It is not quite so strong as the dilute sulphuric acid, for which it forms an agreeable substitute. It is prepared by diluting two ounces of sulphuric acid with two pints of rectified spirit, and digesting in the mixture some powdered cinnamon and ginger.

ACIDUM SULPHUROSUM.—A solution of sulphurous acid gas in water is now officinal. It is to be prepared by putting a mixture of wood charcoal, and sulphuric acid into a glass flask fitted with a bent tube, and applying heat; the evolved gas is first passed through a small waste bottle, and then into a vessel of cold distilled water. The sulphuric acid reacting on the charcoal produces a mixture of sulphurous acid and carbonic acid gases.

$$2\,(S\,O_3\,H\,O) + C = 2\,S\,O_2 + C\,O_2 + 2\,H\,O.$$

The sulphurous acid is absorbed and retained by the cold distilled water, while the carbonic acid escapes. The Pharmacopœia orders sulphuric acid to be used; but we presume sulphuric acid of commerce is meant, and not the redistilled acid. The process given is one in common use, and is very easily conducted. By substituting metallic copper or mercury for the charcoal, the sulphurous acid gas may be obtained pure; but for making a solution of the gas, the production of carbonic acid is of no importance.

Recently boiled but cold water is capable of dissolving thirty-three times its volume of sulphurous acid gas. The solution is very liable to become weakened by evaporation

of the gas ; it is also very prone to absorb oxygen from the air, and form sulphuric acid. It should, therefore, be kept in a well-closed bottle and in a cool place. The presence of the sulphuric acid may be recognised by chloride of barium, which is not affected by the sulphurous acid. The Pharmacopœia directs the strength of the solution to be determined by the volumetric solution of iodine.

One fluid drachm mixed with a little mucilage of starch, should require 164 measures of the iodine solution to produce a permanent blue colour. When iodine comes into contact with sulphurous acid in the presence of water, hydriodic and sulphuric acids are formed.

$$SO_2 + I + HO = SO_3 + HI.$$

Sulphurous acid is very poisonous to plants, and especially so to cryptogamic vegetation. Hence it is used in the treatment of certain skin diseases of parasitic origin.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. BAKER BROWN continues his Clinical Lectures on the "Diseases of Women Remediable by Operation," his present subject being "Recto-Vaginal Fistula." This lesion is most commonly produced by sloughing of the soft parts in consequence of protracted labour. Recto-vaginal fistula and vesico-vaginal fistula sometimes occur in the same subject. The first is cured more easily than the second, because there is no complication from the trickling of the urine. The operation consists in paring the edges of the opening and bringing them together by sutures. The after-treatment of recto-vaginal fistula consists in the administration of opium to keep the bowels confined, and the liberal use of wine and generous diet to maintain the vital powers of the patient, and thus ensure a better union of the parts.——Mr. HOLMES COOTE relates the "Particulars of the Treatment of a Case of Tetanus" in which the Calabar Bean was freely administered. The patient was a healthy looking man, who had had his finger amputated for an injury by an iron roller. Several medicines were administered, namely, croton oil, calomel, the Calabar bean, morphia by hypodermic injection, and quinine ; but although the man recovered, it is not easy to determine to which medicine the cure was to be attributed. He took altogether fourteen minims of the extract of Calabar bean, equal to fifty-six grains of the powder.——Dr. J. MOORHEAD contributes the particulars of an interesting case of "Spurious Encephalitis." The patient was a gentleman, aged sixty-two, who was seized with symptoms somewhat similar to those which indicate congestion of the brain, but which were really due to exhaustion of that organ. The treatment was stimulating throughout, and the result was quite successful.——Mr. HENRY SMITH gives a Report of a case where a "Portion of Tobacco-pipe was Broken into the Bladder, and was Removed successfully after the use of the Lithotrite." The patient was a youth of nineteen, who had introduced a clay pipe down his urethra into the bladder, for some supposed difficulty in micturition. On removing it he found that two inches of the pipe had been left behind. Mr. Smith introduced the lithotrite and broke the portion of pipe into two pieces, and then crushed one of the pieces. The patient afterwards passed spontaneously a portion of the broken part of the pipe, and subsequently all the rest came away, including the part *which had not been crushed by the lithotrite.*—— Dr. G. MACKENZIE BACON contributes a "Brief Account of the Government Regulations on Prostitution in Italy, and of the Sifilicomio at Naples." The regulations now in existence in Italy are very similar to those established in Paris ; and in Naples they have lately been assimilated to those already existing in Northern and Central Italy. The *surveillance* exercised over prostitution is exceedingly strict, the whole of the regulations being enforced in a systematic manner, and according to the statistical returns the results are a diminution of syphilitic disease, and a considerable revenue to the Government.

THE 'MEDICAL TIMES AND GAZETTE.'

Mr. PAGET communicates a clinical lecture on "Some Cases of Local Paralysis." The principal subject of the lecture was a young man who, in consequence of an injury to his head, lost the use of his left arm, which soon began to waste. Mr. Paget relates some other cases of local paralysis, one of which was in one of the lower extremities in a gentlemen who had been thrown from a horse, and had injured his left hip-joint. For cases of local paralysis, Mr. Paget recommends warmth, friction, and shampooing, constant voluntary efforts, and the employment of galvanism. ——Dr. GARROD continues his "Lectures on the British Pharmacopœia," his present lecture commencing with Opium, its Constituents, and Medicinal Compounds. Dr. Garrod believes, as the result of numerous trials, that hydrochlorate of morphia is about four times stronger than opium as an anodyne and sedative ; that the hydrochlorate is quite as good a preparation as any other salt ; that codeia is destitute of the valuable properties of opium. The resins of opium probably possess some active properties, which may account for the difference between the action of opium and that of the salts of morphia. Lactucarium, though not included in the British Pharmacopœia, is noticed by Dr. Garrod, who has employed it in practice, but has found it inefficacious as an anodyne and sedative, although he has given it in very large doses amounting to sixty grains three or four times a day.——Mr. LE GROS CLARK continues his clinical lecture on "Excision of the Knee-joint," an operation which he has performed in seven cases, generally with a successful result. Mr. Clark has never met with serious hæmorrhage, and generally the bleeding is trifling compared with what might have been anticipated, nor has he found the shock to be severe, or that, in his own cases, pyæmia has supervened.—— Mr. JOHN WOOD communicates a paper on "Rupture," and describes the operation he has devised and practised for the radical cure of that affection. He has performed the operation in nearly a hundred cases, with the result of more than two-thirds of cures, and only one death, and that from pyæmia. The object of the operation

is to close the aperture by which the hernia descends, and this is effected by passing silvered wires across the inguinal ring, and skewering or trussing up the sides of the canal; or in more severe cases by invaginating so much of the fundus of the hernial sac and its coverings as to fill up the openings completely, and tying upon it the sides of the hernial canal. The ligatures used by Mr. Wood are made of stout copper wire, silvered over.

The 'British Medical Journal.'

Mr. Brodhurst continues his lectures on "Orthopædic Surgery," his present subject being "Torticollis or Wry-Neck." This affection is sometimes congenital, but more usually acquired, and its most frequent cause is paralysis. The immediate occasion of wry-neck is shortening of some of the cervical muscles, especially of the sterno-cleido-mastoid, and in confirmed cases, the subcutaneous section of this muscle must be practised.——Dr. W. Tilbury Fox communicates a paper on the "Nature of the so-called 'Parasites' of the Skin," being a criticism of an article written on the same subject by Mr. Erasmus Wilson in the last number of the 'British and Foreign Medico-Chirurgical Review.'——Mr. E. Cousins relates a case of "Recent Intussusception in a Child," the malady being relieved by inflation *per anum*.——Dr. T. M. Rooke relates a case of "Large Calculus Impacted in the Urethra, and its Removal." It was lodged in the urethra near its orifice, and as it was impossible to extract it by an ear forceps, the urethra was slit up from the mouth, and the calculus was removed though not without difficulty.

GENERAL CORRESPONDENCE.

A WORD ON THE LECTURE SYSTEM.

To the Editor of the Medical Circular.

Sir,—I am obliged to you for the honour of the able comments with which you accompanied the publication of my letter, and am glad to think that in the main there is little substantial difference in our views. The examining bodies do not, as you tell us, exact even so many as a thousand lectures out of the three or four thousand, which I suggested as offered by the lecturers and also dabbled in by the students. There are, as you remind us, "magnificent museums," invaluable "chemical laboratories," with "long ranges of sick wards," all open to allure the student to the practical study of his profession, and, as you add, the colleges have of late years essayed to encourage the tendency by giving to their examinations a more practical character. But what of all this Sir, if the result be as you tell us, that a sufficient supply of clinical clerks and dressers is not to be obtained, and if, as you add, "with confidence," "a lamentable want of practical knowledge is displayed by candidates at many of our medical and surgical examining bodies?" Whatever the explanation, whether the students are overdone with theory, or underdone with practice, or suffer equally under both disadvantages, the effect appears to be the same. The first moment that the only test that is worth a farthing is applied, they fail; a failure that might mean the loss of everything to some valuable member of society, whose lot it might be to offer the practical test now essayed in more harmless forms in the colleges.

In writing my observations on the excessive development of the "vox et præterea nihil" in our Medical teachings I failed, apparently, to make it clear that I was thinking less of the requirements of the examining bodies, than of the immense supplies of the lecturing element with which our schools find it desirable to compete for the preference of students, now consulting the last programme of an establishment which claims to offer the *ne plus ultra* of a modern medical education, the University College School, how many courses do your readers think are offered to the neophyte? In addition to practical pharmacy, to anatomical demonstrations, and to three courses on clinical midwifery, clinical medicine, and clinical surgery, I find there are eighteen courses set down, and if "logic" happen to be one of these, the explanation is added, that it is at all events necessary for the candidates of the Army Medical Department. Only think of eighteen courses! As the three clinical courses I have named, taking the lecturers to keep their promise of giving seven a week, would amount alone to a thousand or more in the four years, how alarming is the total reached, when we think of eighteen more courses under delivery with more or less frequency during the week through the same periods, and always tempting the attendance of men who, having paid "perpetual for the whole," do not easily reach the assurance that they have received their money's worth? For their own sakes it is to be hoped that they never attain to the self-inflicted misery of listening to the three or four thousand at which I roughly estimated their number, but if they do, I will only say that a conversation with one of them, as met on his return from attending a lecture, heard perhaps for the fourth time, would be more interesting than even the explanations of Demasippus, whose impressions after a somewhat like occasion, are described for us in the "Unde et quo" of Horace. But, if in a school, under such modern organization as that of Gower street, we have the professors offering so many temptations to withdraw their pupils from all the more useful arenas of their duty—how must it be in Edinburgh, where, as Mr. Syme complains, matters are still worse, and where, as he assures us, "the students have seldom in their second or third years more than one hour in the day available for the dissecting-room?"

The truth is, this "theory, theory, theory," is the error and vice of all our systems of teaching, and has possessed itself of our Medical system more than of any other in the proportion that it is more out of place. All the senses are placed on the superannuated list in favour of the ear, and the thoroughly experienced physician or surgeon, who remembers that he began practice with twenty theories for every disease, and fifty sure modes for their treatment, and now has scarcely more than one remedy for fifty diseases, and no satisfactory theory to account for any fully, as he hears some young professor teaching him how to deal with the old foe with many faces, must feel much as old Hannibal must have done when hearing the Asiatic Professor eloquently expounding to him the only sure mode of taking rich cities, and winning great battles.

The views on the great laws of nature, and on the adaptation of means to the actual exigencies of our human experience, are only to be acquired by a very thoughtful observation of whatever phenomena fall within the range of our duties, and that inner digestion of our own knowledge which makes it an almost original part of our own organization. Without this, we may, like Hamlet's courtiers, acquire the tune of the profession, and a certain airy dexterity, which may carry us through the "habits of outward encounter," but once blown to our trial, "the bubbles will out." As the Irish farmer said to some celebrated agricultural chemist lecturing on the improvement of soils, and whom he had perhaps listened to by the light afforded by some instructive failures in the neighbourhood, "Your thaoury may be all very fine, misther, but for my part, sur, give me the craps." The lecturer thought Pat a dull scholar for seeing no connexion between the two; but who knows if he was not as near the mark after all as his master?

I am, &c., Vigil.

The Medical Mission at Canton have resolved to enlarge the hospital connected with the mission. Towards this object nearly three thousands dollars have been received. Dr. Colledge, F.R.S., at present in England, has been chosen President for the ensuing year.

THE MEDICAL CIRCULAR.

WEDNESDAY, MARCH 30, 1864.

GRATUITOUS MEDICAL SERVICES.

The death of a woman at Birkenhead, from hæmorrhage after delivery, and without Medical assistance, has given rise to a somewhat sharp discussion, on opposite sides of the question, between the 'Medical Times and Gazette' and the 'British Medical Journal.' It appears that the poor woman with her husband came to Birkenhead about six weeks since, and had engaged no Medical attendant, and in the beginning of the present month late one night she was taken in labour. The husband went in succession to the houses of six Medical men, but none of them would attend, and one of them is reported to have said that "he would not turn out till a guinea was put into his hand." At last one of them who had gone to bed ill, and who had therefore refused to go at one o'clock in the morning, was again applied to at four, and being adjured to come and save the woman's life, obeyed the summons, but his services were too late, as the patient was pulseless, there was no brandy to be had, and she sank.

There was a Coroner's inquest, and, of course, several severe observations were made by some of the jurymen against the Medical Profession, but the Coroner explained to them that there was no law to compel a Medical man to attend a case unless he pleased, and that the real blame rested on the deceased herself and her husband in not engaging Medical assistance on their first arrival in the town.

This painful but by no means unusual circumstance has, as we have just observed, given occasion for some smart sparring between our two contemporaries, the 'British Medical Journal,' applauding the six doctors for their refusal to obey the summons, and congratulating the Medical Profession at Birkenhead for the healthy state to which they had been brought on the subject of gratuitous Medical services; while the 'Medical Times and Gazette' denounces the whole transaction as a disgrace to the Medical Profession throughout the world, and severely takes to task the writer on the subject of Gratuitous Medical Services, in the 'Journal' of the Association.

The 'Medical Times and Gazette' scorns the idea of the Medical Profession being in any way influenced by trading notions, and urges that a Medical man should always act for the benefit of others and not for his own; that he should cultivate science for the interest of his fellow-creatures; that he should give away his services to all who are unable to pay for them; and that when he receives anything he should take it as a gratuity, which may be greater or less according to the means of the person benefited, and should never claim it as a right. It therefore follows, according to this reasoning, that in a poor neighbourhood, Medical men should fix their abode solely to relieve the sufferings of their neighbours, that they should be ready to wait upon them day and night for the love of science, and that they should expect their reward from the advent of some peer or millionaire from Belgravia, whose bounty would compensate for the penury or dishonesty of the rest of the district.

Now, we do not condemn the sentiments of the writer of the article in the 'Medical Times and Gazette;' we only declare them to be Utopian. He may probably be some Oxford or Cambridge graduate, fresh from College, warmed by the generous and enthusiastic notions inspired by the perusal of the standard writers in ancient and modern literature, and full, to overflowing, of confidence in the innate goodness of human nature. Or perchance he may be some middle-aged or elderly practitioner on whom fortune has been benignant with her gifts, whose coffers have been always well filled with inherited wealth, or whose richer patients shower upon him in profusion the golden rain which captivated the heart of Danae, and which even to the philosopher is seldom unacceptable. We heartily hope that such may be the case, and that many of our brethren are in this happy condition, which naturally has a tendency to tinge with a roseate hue our views of human life, and to create generous sentiments towards all mankind.

But, unhappily, there are a vast number of our professional brethren, and we fear they are the great majority, whose condition is the reverse of that which we have just shadowed forth; whose generous feelings have become blunted by intercourse with a hard and unfeeling world, whose means have become exhausted by their unavailing efforts to obtain a maintenance, and who, even if successful, are barely able to keep the wolf from the door. Such men would probably inform us that the writer of the article to which we refer is a mere visionary, and that if his views were carried out in actual practice, the universal bankruptcy of the Medical Profession must ensue. They would tell us that a great multitude of patients do not pay them, and that they never intend to pay; that some intend to pay and are not able to do so, and that some who intend to pay while they are ill, forget all about the matter when they are well. As far as the higher and the richer walks of life are concerned, many a practitioner could tell us that such persons do not throw away their guineas indiscriminately on the deserving members of our Profession, however much they may patronize quacks and pretenders of all descriptions, and that instances are not wanting where even some of this favoured and exalted class will not hesitate to cheat the Doctor, if it can be done in a genteel way.

Hence, therefore, we cannot altogether endorse the enthusiastic views entertained by our contemporary, although at the same time we cannot treat the Birkenhead case quite so lightly or so exultingly as is done by the 'British Medical Journal.' We cannot believe, and we do not believe, that any member of our Profession would willingly and knowingly allow a fellow-creature to die, any more than we should believe that he would refuse to extricate from the water a person in danger of drowning, or from the fire a person in danger of being burned. We rather believe that the announcement that the poor woman at Birken-

head was dying, was received with that natural incredulity which results from the fact that most applications to Medical men are expressed in those exaggerated terms, for the purpose of obtaining prompt attention, and was neglected on the same principle that the child who cried "wolf" so often, at last received no assistance when the wolf had really come.

There is justice in what the 'British Medical Journal' states about the Medical Profession having a heavy and long unsettled claim against "society." It is "society" which too often cheats the doctor, makes him work for little or for nothing, recompenses him but scurvily when he deserves recompense the most, and abuses and ill-treats him whenever it can. We have no wish to hear of a repetition of the Birkenhead calamity, which, after all, might have been averted by an application, on the part of the sufferer, for paid Medical advice, or for the aid afforded by some of those charitable institutions in which our country abounds; but at the same time we hope that the Profession will hereafter put a fair value on their own services, and either persuade or compel the public to estimate them at an equitable rate.

THE INSURANCE OF THE POOR.

[COMMUNICATED.]

Mr. Gladstone's Industrial Annuities Bill is exciting a notice amongst us altogether disproportioned to our interests in it. As a profession, we have as little to do with it as many are individually fancying that we have much. It concerns the Government and the assurers—but beyond them whom? They propose to have a business transaction together, and may reasonably stipulate whatever conditions they please as to the contract that is to bind them to one another. If they want our assistance, they can have it on precisely the same principle. We in our turn are the masters to fix our own conditions. We may safely leave their bargain to the ordinary laws of commerce. If unfavourable to the industrious assurer, the law will prove a dead letter. If over favourable, the advantage will not be considerable enough to be worth our protest; for who would be at pains to amplify about some trifle exceeding which would be after all but a premium on honest thrift. A Medical man can hardly expect much from a system of insurances meant exclusively for the poor, and implying payments that will average but a few pence a week. Where there is nothing, says an old proverb, the king loses his rights; and men who have a reputation to maintain as members of a learned and gentlemanly profession would find it hard, probably, to reconcile the dignity of their position with taking a share as "experts" in bargains in which the advantage rendered would so rarely be worth the expense of time and money at which it would be secured.

The data of age, occupation, and general good health, may not furnish very conclusive evidence or a perfectly equitable contract; but what matters it if there be some slight miscalculation, and an average on large numbers being formed, who shall say that the steadiness and good sense implied by the very proceeding may not bring right results which calculated on other bases, would probably be unsatisfactory?

It is our money to be sure that is dealt with as much as that of any other portion of the community, and without waiving our interests as consulting authorities on one side, we may not unreasonably claim to be guardians of the public purse on the other. There is, however, some difficulty in reconciling pleasantly the two positions, and a professional movement about the trifles that alone are really in question, would be as undignified as some of the parochial tempests elicited by Medical Officers when claiming from Poor-law Boards a becoming repayment of their public services. And if it be indeed "our money" that is to make good the possible loss through inequitable insurances, it may be that our interference would not make the loss much less, or compensate for the difference or the injury arising to the great object of the proposed law by any corresponding good effect on our professional standing. The experience supplied by our Medical relations with the benefit societies is not an encouraging one. It is not pleasant to think about a worthy colleague with the diplomas of the College of Surgeons and the Society of Apothecaries in his pocket, walking his three or four miles to earn the sum of four pence by a professional consultation. Better occasionally that assurers against sickness and death should make a mistake than that the members of a learned profession should be degraded by being made the instrument of such humiliating exigencies.

SUMMARY OF THE WEEK.

THE MEDICAL COUNCIL.

Although the proceedings of the Branch Meetings of the Medical Council are not officially communicated to the public press, and although, in fact, the Report of the last sitting in London was sent out only in a private and confidential manner, it has transpired that a resolution has been passed to the effect that the Branch Council for England having given their attention to the Report of the Medical Acts' Amendment Committee, are of opinion that it is not expedient at the present time to engage in fresh legislation. The exact meaning of this resolution is not very apparent at first sight, but it will become intelligible when coupled with the recent small agitation in favour of legislation for the chemists and druggists, and the more important question of defining the meaning of certain clauses in the Medical Act, the interpretation of which has hitherto caused considerable discussion, and involved great disappointment to the Profession. As far as the proposed changes in Pharmacy are concerned, we stated long ago that there was no chance of their being carried, as we knew that the English Branch Council was entirely opposed to the scheme, which was concocted on the other side of the channel, and was founded upon the existing state of Pharmacy in Ireland. But if the resolution also affirms that the Act of 1858 requires no amendment so as to make its operations more effectual in suppressing illegal practice, we deeply regret the decision

of the Branch Council, for we think that it is the duty of the Council to press the Legislature to render clear and distinct many clauses in the Act, which lead at present only to confusion and misapprehension.

THE COLLEGE OF PHYSICIANS AND THE NEW PHARMACOPŒIA.

At a recent meeting of the Fellows of the Royal College of Physicians of London, the worthy and excellent President, Dr. Watson, who was unanimously re-elected, observed *inter alia*, that he believed he was expressing a general and deeply-rooted opinion when he said that the New Pharmacopœia had occasioned great disappointment and perplexity, and that many of the changes which had been introduced, such as that in the atomic constitution of corrosive sublimate, were not only injudicious but highly dangerous. He stated that he himself had not been able to master the details of the new work, and he understood that many of the Fellows were in a similar predicament. We may take leave humbly to suggest that it was from an apprehension of this kind that we commenced and are now continuing in the MEDICAL CIRCULAR a series of able and elaborate papers on the British Pharmacopœia, by writers of tried and acknowledged reputation, and that if the learned President and the Fellows of the College, together with the mass of the Profession generally, will peruse those articles for about six months, we will promise them a considerable addition to their existing stock of knowledge. We are no apologists for the new Pharmacopœia, and we have boldly exposed many of its errors and absurdities, but, nevertheless, it may be taken as an instalment of something better to come hereafter. In the meantime, and while the College of Physicians are mastering the details of the new work, we willingly second the recommendation of the President, that Medical men should for the present continue to prescribe according to the London Pharmacopœia, only taking the precaution to write P. L. or Pharmacopœia Londinenses at the top of the prescription.

REVIEW OF BOOKS.

Proofs of the Non-existence of a Specific Enthetic Disease. Addressed to the Secretary of State for War. By David Macloughlin, M.D. Pp. 58. London: Churchill and Sons.

In point of bad reasoning, bad taste, bad grammar, and bad spelling, this is one of the worst pamphlets we have ever seen. The object of the writer is to prove that there is no such thing as syphilis, and therefore no necessity for curing it, or of preventing its propagation. In the year 1814, Dr. Macloughlin attended two soldiers, both of whom had ulcers on their genitals. One had mercury administered to him and died in two months; the other had no treatment at all, except washing the sores, and he recovered in eight days. Hence, we presume, we are asked to believe that in the one case the patient was killed by the treatment, and in the other that the patient recovered because he had no treatment. But moreover, some of the most distinguished surgeons have declared their inability to point out the exact diagnosis between a primary syphilitic ulcer and one which is not syphilitic; therefore, there is no such thing as a true syphilitic ulcer, and the medical treatment of the so-called syphilitic disease annually deprives the army of the services of thousands of men, even if it does not, as Dr. Macloughlin broadly hints, destroy the lives of thousands. The Army Medical Department knows nothing about the so-called syphilitic disease, having never studied it scientifically; and the civil surgeons understand it just as little as their military brethren. Such is the trash put forth in this pamphlet, which lugs in the names of some of the most experienced practitioners in France and England, as being favourable to the views advanced, and for this compliment the practitioners in question will no doubt be duly grateful. It would be a waste of words to notice this production any further.

On Diabetes and its Successful Treatment. By John M. Camplin, M.D., F.L.S. Third Edition. Revised, with Additional Notes and Observations, by J. G. Glover, M.D. Pp. 104. London: Churchill and Sons, 1864.

The author of this little work was unfortunately carried off by death while he was preparing the materials for a third edition, and his literary executors have thought it advisable to meet the demands of the Profession by presenting it in its new and slightly enlarged form. As far as revision is concerned, there is very little to be said in the way of commendation, for the author's additional manuscript seems to be in the same state as where he left it; the punctuation being entirely neglected in the later passages, and the sense therefore being very obscure.

The work itself is already favourably known to the Profession as a species of autobiography, written by a gentleman of no great scientific attainments, but who wrote from personal experience on the treatment of a disease, from which he himself was a sufferer, and from which he obtained very considerable relief by adopting the dietetic and medicinal regimen he has described in his pages for the benefit of the community. Regarded in this light, it is a very useful monograph, and is characterised by a modest tone, as the author makes no pretension to having discovered any specific remedy for the malady of which he treats. He lays, however, very great and just emphasis upon the benefits derivable from a strict attention to diet, and an abstinence from sugar and starchy substances; and the now well-known bran bread and biscuits, the formulæ for which were devised by Dr. Camplin, form most important articles in the successful management of what is too often a fatal, and always a most alarming disease.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 23.

Mr. PRESCOTT HEWETT, President.

Mr. SYDNEY JONES brought forward a boy who had

NUMEROUS EXOSTOSES.

They were very numerous, and were situated chiefly on the lower extremities; but there were some on the ribs and on the bones of the arms. They were symmetrical. Mr. Jones said that, as the boy's parents would not permit any operation to be performed, dilute nitric acid was given internally, and, he thought, with some benefit. None of the exostoses were larger, and some were certainly smaller.

Mr. W. ADAMS referred to cases of multiple exostoses under his care at the Orthopædic. They were, he said, invariably symmetrically placed and symmetrically developed. He had never given nitric acid. In ninety-nine out of one hundred the growth spontaneously ceased. He had seen cases ten years after they had ceased to grow. If an acid were to be given, he should, on theoretical grounds, prefer the phosphoric.

Mr. SYDNEY JONES said that he commenced the treatment by phosphoric acid; but he was found fault with for using it. It was said that if there were an excess of lime in the system, the acid would form with it phosphate of lime, and thus furnish more material for deposition.

Mr. HULKE said that the growth of the exostosis was due to the cartilaginous layer over it rather than to an excess of earthy matters in the system.

Mr. SYDNEY JONES thought that if there were an excess of phosphate of lime in the blood, the tendency to the increase of the exostoses would be greater.

Dr. SANDERSON suggested that it would be well to give distilled water in such cases.

Mr. BROOKE asked if lactic acid had been tried, as it was said that lactic acid removed excess of phosphate of lime.

Mr. SQUIRE exhibited

A MALE CRAB LOUSE.

This was a rare specimen, as Kuchenmeister had only examined females, and Moquin-Tandon makes no mention of the male. The male differs considerably from the female. Mr. Squire also exhibited a photograph taken from the microscope, and suggested that more use should be made of photography to delineate microscopical specimens in pathology.

Mr. HENRY SMITH exhibited

PARTS REMOVED IN EXCISION OF AN ANCHYLOSED KNEE.

A soldier was shot in the knee-joint at Inkermann. Violent inflammation followed, but he at length recovered with a stiff knee, and was enabled to act as a Commissionaire for six or eight years. At the end of this time inflammation again set in. When Mr. Smith again saw the patient the limb was bent nearly at a right angle, and was nearly useless. Mr. Smith removed a wedge of bone, and thus restored the limb to the straight position. He was able to remove just enough to get the leg straight by the two incisions necessary to cut the wedge. The patient, a tall, healthy man, recovered. His limb was quite anchylosed, and he was now overlooker at a mine in Wales, and could walk twelves miles a-day.

Mr. HENRY LEE said that excision of the knee-joint was not so successful in adults as in children. He had recently removed a segment from the anchylosed knee of a child with an excellent result.

Mr. HENRY THOMPSON thought the case should scarcely be called one of excision of the knee-joint.

The PRESIDENT remarked that the operation was rather to be thought of as one of excision of bone than as an excision of a joint. The joint was quite gone, all the parts being fused together.

Mr. TEEVAN exhibited

AN OBTURATOR HERNIAL SAC.

It was taken from the body of an adult male which came into the dissecting-room at Westminster Hospital. The sac was about an inch long, quite empty, and had protruded before it a considerable piece of the subperitoneal fat. There was also in this subject extensive tubercular affection of both lungs, together with a scirrhous cancer of the rectum.

The PRESIDENT then related a case in which a patient with symptoms of strangulation, and who had protrusion of the femoral ring, was operated on, as for femoral hernia, but no intestine was found. The symptoms continued, and the patient died. At the autopsy, strangulated obturator hernia was found. The President remarked that Mr. Obré was the first to diagnose strangulated obturator hernia during life, and thus to save the patient's life.

Dr. MURCHISON read a report on Mr. Pitt's case of obstruction of the bowel by a concretion. The concretion contained a good deal of cholesterine, and was no doubt of biliary origin. Dr. Murchison also showed another like specimen, by which the small intestine had been obstructed; but in this case there was a fistula between the duodenum and the gall-bladder.

Dr. DICKENSON showed a piece of bowel from a patient who died of

TYPHOID FEVER.

A boy, a sweep, died of typhoid fever on the sixth day. He had had no spots, but diarrhœa and abdominal tenderness. All the solitary glands in the small intestines were in a state of great prominence, nearly as large as peas; they had large, round heads, and narrow necks. Peyer's patches were swollen, and one or two were ulcerated near the valve.

Dr. MURCHISON did not think such appearances rare in typhoid. In some cases Peyer's patches, in others the solitary glands, were chiefly affected. Such a condition of the solitary glands had led some to compare it with variola.

Dr. MURCHISON exhibited a specimen of

ABSCESSES IN THE KIDNEY FROM A PATIENT WHO HAD HAD TYPHOID FEVER—PYÆMIA (?).

The patient, a girl, aged nineteen, died on the forty-second day. On the thirtieth day she was well of the special typhoid symptoms, but still did not get on, but became more and more emaciated; but she had no rigors, and none of the ordinary symptoms of pyæmia. After death, ulceration of the intestines was found, presenting good specimens of the atonic ulcer. The spleen had returned to its natural size, and the mesenteric glands were not enlarged. In the kidneys were several small abscesses. There was no other evidence of pyæmia.

TESTES FROM AN HERMAPHRODITE SHEEP.

Dr. Wilkes exhibited some testes which had been given him by Mr. Turner, of Bermondsey, and which had been taken from an ewe sheep. The animal had always been regarded as a female sheep, and was cut up as such by the butcher. The testes were found in the groin. Each consisted of two rounded bodies placed one over the other; the lower was evidently an undeveloped testis, but the upper was of a more doubtful nature. It contained several large tubes, and Dr. Wilkes thought it might be the remains of a Wolffian body. The vas deferens ended in a blind extremity. Dr. Wilks alluded to the fact of too much stress having hitherto been laid upon the fact of an animal possessing undeveloped testes as determining the sex. A more modern investigation, such as that of Mr. Curling, had shown that a testis retained in the body, and of the character described, was functionally powerless, and thus its possessor might have none of the attributes of the male sex. What was remarkable, however, was the fact that in such instances the animal often put on the character of the female. It was so in the present example. John Hunter had remarked the same in oxen, and in the human subject similar cases had been observed. Dr. Wilks mentioned the instance of a person who possessed every feminine quality except the essential sexual character, and yet in this person undeveloped testes existed. Although she had always been considered a woman by herself and friends, she was now (as regards the undeveloped organs) to be placed in a bottle, and ticketed as a male. There did not seem sufficient reason for so doing. Although the poet Tennyson had declared that "Woman was not undeveloped man, but diverse," this doctrine had not been physiologically proved.

Dr. WALE HICKS exhibited a specimen of

MALFORMATION OF THE GREAT VESSELS.

This specimen was taken from a child who died on the fourth day. The true aorta, arising from the left ventricle, was small, and gave off only the innominate and the left carotid and subclavian arteries, while the artery given off from the right ventricle was very large, and after giving off the pulmonary arteries, was continued over the left bronchus as the descending aorta. The septum ventriculorum was perfect. The same child was the subject of crania bifida, a circular opening in the occipital bone forming a communication between the cranial cavity and a sac formed of dura mater, lined by serous membrane, and containing fifteen fluid ounces of blood-stained serous fluid.

Dr. GIBB exhibited for Dr. Grant, of Ottawa,

A DRAWING OF THE HYPOGASTRIC REGION OF A LAD AGED TWENTY,

with eversion of the bladder, absence of the normal umbilical cicatrix, and deficiency of the corpus spongiosum. There was constant dribbling of urine, and consequent irritability of the surrounding skin. Directly above the pubes was a projecting growth, red, villous, and exceedingly vascular, three inches broad, and divided into three lobes, the whole structure arising from eversion of the bladder. The penis was rudimentary. There was a congenital inguinal hernia of the left side, and both testes were normal, and so was the body in other respects.

Mr. HINTON exhibited a specimen from a case of

LARGE AURAL POLYPUS.

The specimen was taken from a man, aged 42, who died

from an injury. A fibro-cellular growth occupied the whole meatus of the left petrous bone, and protruded from its orifice. It was attached to the periosteum of the canal at its superior part, but took its origin chiefly from the cavity of the tympanum, which it seemed entirely to fill, being attached to the whole of its walls except the inner surface of the membrana tympani, the upper third only of which was destroyed. The Eustachian tube was not obstructed, but the growth was attached all around its tympanic orifice.

The upper portion of the mastoid cells also were filled with a similar fleshy mass. There was no disease of the bone. The right ear was healthy.

Mr. HINTON showed also

THE PETROUS BONES TAKEN FROM A BOY, AGED 16, WHOSE SKULL HAD BEEN FRACTURED BY MACHINERY.

In this case the line of fracture passed from near the left orbit through the petrous bone of the opposite side (the right); it took the line of the Eustachian tube, and the membrana tympani was separated from its attachment to a small extent at its most superior part. There was profuse bleeding from the mouth and from this ear. From the other ear also, although not at all implicated in the fracture, a few drops of blood had escaped; and on examination it appeared that the membrana tympani had been detached in exactly the same spot as on the opposite side, thus indicating a line of force traversing the skull on this side corresponding to the direction taken by the fracture on the other.

HARVEIAN SOCIETY.

MARCH 3RD.

PRESIDENT, WM. ADAMS, ESQ., in the Chair.

Dr. HICKMAN related the following case: A man, a butler, aged thirty-two, expired suddenly. He had been quite well on going to bed, and a young man going to fetch him found him lying dead. On making a post-mortem examination thirty hours after death, no clear cause of death could be discovered. The blood was fluid. There was no disease of the heart or great vessels; right side of the heart flabby and full of blood. Brain and kidneys healthy. Naturally suspecting that this might be a case of suicide, he removed the stomach for analysis. At the inquest, however, there was no evidence tending to prove that there was the slightest probability of suicide, nor was there any history of previous illness. Consequently, Dr. Hickman could not pronounce as to the cause of death, and the verdict was left an open one. On examining the contents of the stomach for prussic acid, none was discovered. Since the inquest he had ascertained that the man had for some time complained of pain in the side, and that he had had a fit. For many years he had complained of pain in the side after walking fast. Did the man die of angina pectoris?

The PRESIDENT asked whether the coronary arteries had been examined?

Dr. HICKMAN replied in the negative.

Mr. JAKINS asked whether the arteries in the brain were healthy?

Dr. HICKMAN replied in the affirmative.

Dr. BALLARD mentioned two cases of sudden death which had come under his notice. 1. A man with orchitis was lying on a sofa with a lotion on his testicle, otherwise in perfect health, but he suddenly died, and after death no lesion could be discovered sufficient to account for this fatal result. 2. A magistrate, a patient of his, had been at Goodwood races a few days before his death. On that day, however, at twelve o'clock he was walking up and down Marylebone lane. Being constipated, he asked Dr. Ballard to give him something to relieve him, and Dr. Ballard sent some medicine and an enema. About an hour afterwards he expired suddenly at stool. On post-mortem examination, the coronary arteries were found to be ossified; but otherwise the body was perfectly sound.

Mr. SEDGWICK related a similar case of sudden death: A young man had gone to bed a little ailing. His landlady had administered a warm drink to him as he complained of feeling poorly. When she awoke she found him dead, and that he had been dead for some time. There were no post-mortem appearances sufficient to account for the death, though the body was thin and the heart weak; consequently, the verdict was left open. The young man used oxalic acid in his trade; but none was found in his stomach.

Dr. TILBURY FOX mentioned the case of a coachman of Dr. Walshe, who, having been rather unwell the day before, was brought into University College Hospital, and died in a few hours afterwards. No post-mortem appearances were found to account for death. There was some albumen in his urine, which might possibly have poisoned the brain and caused stoppage of the heart's action.

Dr. HICKMAN remarked that uræmia seldom causes death of so rapid a kind. He thought some alteration ought to be made in coroners' law, as such cases were slurred over, and there was a disposition on the part of some coroners to come to a verdict too rapidly.

Dr. COCK mentioned a case of spontaneous gangrene occurring in a child aged eight. The child had been feverish for some days, when its left thigh began to swell above the knee and upwards. There was no pulse in the artery or in the posterior tibial. The liver was mottled, cold, and shrunken.

Dr. HART VINEN thought it probable that a plug of fibrine had been sent into the artery and had blocked it up.

Dr. BALLARD mentioned that Dr. Murchison had seen thirty or forty cases of phlegmasia dolens after typhoid fever, almost all occurring in the left thigh.

Dr. VINEN had seen lately such a case in the left thigh after typhoid fever.

Dr. HICKMAN had seen lately a case of spontaneous sloughing of the skin of the feet, small in extent, but occurring in both feet. The arteries were patent and there was great pain. Also a case of sloughing of skin of the breast in a young woman.

Mr. ADAMS had recently had a phagedænic ulcer under his care, extending down deeply, almost as far as the bone. No special history was attached to the case, except that the patient, a girl, had been kicked on it. This was the largest sloughing ulcer he had ever witnessed, and he now had some difficulty in making the foot a useful one. The girl was not at service. He had at present also a case of sloughing of both feet from frost-bite. Both legs and feet were much swollen.

Dr. DRYSDALE related a case where death had apparently been caused by the inhalation of sulphurous acid gas. The patient, aged thirty, a healthy young man, without hereditary taint, was, with two other workmen, employed in a gallery at the mint, where all three were involved in the fumes of the gas. He was rendered insensible, and on recovery felt a tightness at his chest. About a week afterwards he had profuse hæmoptysis, and after this the percussion note was high pitched under both clavicles, but most under the left. Profuse sweats ensued, and all the symptoms of phthisis pulmonalis. He was able to walk about, but in four weeks he became insane, and being taken to Hanwell, he died shortly. No post-mortem was allowed.

Dr. HART VINEN mentioned that a child he had seen had become insane after drinking sulphuric acid. He thought that phthisis pulmonalis and insanity were very frequently observed together and related.

Dr. T. FOX thought it possible that this case might have been one of acute abscess of the lungs without tubercles.

Dr. COCK thought it probable that, although the man had no hereditary predisposition, still he might have been as a townsman, in a condition liable to the outbreak of the tubercular crasis.

Dr. HICKMAN thought that the delirium at the latter part of this history might have been caused by tubercular meningitis.

PROPOSED NEW LUNATIC ASYLUM AT NORWICH.—The Commissioners of Lunacy having objected to the present building and site, the Town Council of Norwich have resolved upon erecting a new asylum.

OBITUARY.

R. A. FROGLEY, F.R.C.S.

Ralph Allen Frogley was born and educated in the town of Hounslow, afterwards the scene of his honourable and successful career. His professional studies were conducted in London, at the Hunterian School in Great Windmill-street, and at St. George's Hospital. He obtained his diploma at the Royal College of Surgeons in the year 1812, and forthwith commenced the active practice of his profession. He was compelled to this step by the complete failure of his father's health, to whose fast declining practice he succeeded. In the field of usefulness thus open to him he speedily established his own reputation and a very lucrative practice This he conducted single-handed till the close of the year 1839, when he received his former pupil and assistant, Dr. Emmot (since of Egham), into partnership. He was subsequently associated in practice with Dr. Hall, now of Brighton, a gentleman well-known to the profession, and of high repute in that town; and lastly with his worthy successors, Messrs. Bullock and Douglas, who at present successfully carry on the practice. Mr. Frogley was elected a Fellow of the Royal College of Surgeons in the year 1852. He was married to Mary, daughter of the Rev. John Neville Freeman, vicar of Hayes, who survives him, by whom he had no family.

In Mr. Frogley the profession and the public have lost one of the most able of the hard working surgeons who have devoted their time and energies to practice in a country district—a position in which all the capabilities of the physician and operative snrgeon may at any time be called into requisition, while the same individual should possess aptitudes to perform with equal efficiency the minor ministrations of the ordinary family medical attendant. Few have been more fitted by natural attributes to succeed in all these branches of professional practice. By the nobility and gentry of his neighbourhood he was received on terms of intimacy and friendship, while his professional services were highly appreciated by them. But it was amongst the poor that his natural benevolence of disposition and kindness of heart found their full scope. To them, as a labour of love, he ungrudgingly gave his skill, his energies, his time, and his money that he might alleviate their sufferings in the time of sickness and danger; and in return they freely accorded to him their gratitude and love. He was endowed with great physical strength and powers of endurance—qualities so essential to the unremitting performance of arduous duties occurring and recurring at all hours of the night and day, and at considerable distances from his home. In addition to his private practice, he officiated for many years as surgeon to the parishes of Heston, Norwood, Southall, Feltham, Hanworth, Bedfont, Cranford, and Harlington.

With great activity of mind and body, Mr. Frogley was gifted with more than ordinary powers of observation—with a sound and cautious judgment which gave him an almost intuitive insight into the difficulties and dangers of the cases brought under his consideration. In the management of the untoward occurrences and complications incident to obstetric practice, where promptness, judgment, and operative skill are all important, Mr. Frogley was acknowledged to be pre-eminent. He was also deservedly in high repute as an operating surgeon. To his skill and efficiency in this branch of practice he principally owed his fame and success in life. The writer has witnessed the dexterous performance by him of all the principal operations of surgery. Amongst these may be mentioned lithotomy, reduction of hernia, ligature of the carotid artery and of the common femoral artery, and various amputations. Two successful cases of amputation for enchondroma of the femur will be found narrated in the "Medico-Chirurgical Transactions," vol. xxiv. In one of these cases the limb was removed immediately below the trochanter minor, the incisions being made so as to admit of disarticulation at the hip joint if found necessary. The limb when removed, with the tumour, weighed four stone—one-third of the entire weight of the patient before the operation. His reputation as an operating surgeon, and as an experienced and skilful obstetrician, naturally led to his being consulted in cases of difficulty by many of his brother practitioners residing in the adjoining villages—a compliment paid only to those in whom great integrity of character is known to be associated with superior talent.

With unswerving resignation to the will of the Almighty he suffered for the last four years of his life from that lingering and debilitating disease, diabetes; to which were latterly added valvular disease of the heart, anasarca, and pulmonary congestion. Under these maladies his strong constitution ultimately succumbed. He departed this life on the 15th instant, aged seventy, in peace with all men. His loss will be deplored by all who knew him well, and his memory will ever be held by them in the highest esteem.

His funeral took place in his native town; and the thronged thoroughfare, the arrest of business, the closed shutters, silently, but feelingly, showed that his fellow-townsmen were sensible that a great and good man had passed from amongst them.

DEATHS.

BRADY.—On the 16th inst., Dr. T. Brady, of Upper Temple street, Dublin, aged 62.

HAMILTON.—On the 10th inst., J. Hamilton, L.R.C.S.Ed., of Dungannon. Co. Tyrone.

KING.—On the 18th inst., at Gibson square, Islington, G. King, Inspector-General of Hospitals and Fleets R.N., aged 73.

MACKENSIE.—On the 17th inst., at Cheltenham, T. Mackensie, C.B., late Inspector-General of Hospitals, Bombay.

QUINTON.—On the 14th inst., W. Quinton, M.R.C.S.E., of Cannock, Staffordshire, aged 53.

RANKINE.—On the 15th inst., at Beulah Lodge, Helensburgh, Dr. J. Rankine, late of Blackwood, South Australia, aged 61.

SMITH.—On the 19th inst., at Caroline street, Bedford square, Mary Anne, the wife of Henry Smith, F.R.C.S.E., aged 35.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:—At a General Meeting of the Fellows held on the 21st instant, the following gentlemen, having undergone the necessary examination, were duly admitted Members of the College:

Frederic Bagshawe, M.B. Cantab., 21, Connaught-square; James Alexander Grant, M.D., Montreal, Ottawa, Canada West; William Henry Witherby, Coombe, Croydon.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 17th inst.:—

Edward Colden, St. George's Hospital; John Henry Edwards, Llangefni, Anglesea; William Gandy, South-street, Park-lane; William Garlick, Park-square, Leeds; Daniel Isles, Fairford, Gloucestershire; Joseph Morris, Studley, Warwickshire; Harvey John Philpot, Wilton-terrace, Kensington; Charles Richard Price, London Hospital; Edward Peter Shorland, Westbury, Wiltshire; Algernon Newbegin Watts, Westminster Hospital; Walter Whitehead, Windermere; John Hargreave Wraith, Over Darwen, Lancashire.

The following gentleman also on the same day passed his first examination:—

Frederic George Denton, Hornsea, Hull.

SMALL-POX AT PORTSMOUTH.—The small-pox has made its appearance to a considerable extent amongst the soldiers and sailors at Portsmouth. There are many cases in the hospital.

HARVEIAN SOCIETY OF LONDON.—The next meeting of this society will be held on Thursday, April 7, at eight p.m., when a paper will be read by Mr. Weeden Cooke, "On the Tumours affecting the Female Breast;" following a discussion "On Diphtheria."

VITAL STATISTICS OF THE ROYAL NAVY.—The latest report of the health of the navy, recently issued, is for

1860. That year the total force of the service is estimated at 64,025 officers and men. Of this number 938 died, or in the ratio of 14.7 per 1,000 of the mean strength. Of these deaths, 712 were from disease, and 226 from violence, chiefly by drowning and falls from aloft, for only 4 were from wounds received in action. The death-rates, therefore, from disease and from violence respectively were 11.1 and 3.6 in every 1,000 men employed; so that of every four deaths in the service, in 1860, one was accidental or violent, and three were the result of disease. Besides the losses by death, 2,844 men, or fully thrice the number dead, were invalided or discharged out of the service in consequence either of chronic and inveterate disease or of the results of injuries. What proportion of these men died on shore after their discharge there are no means of determining. That many must have sunk under these maladies may be presumed from the fact that between a third and fourth of the whole were labouring under pulmonary (chiefly phthisical) or cardiac disease, or under the effects of dysentery. The total number lost to the service by death and invaliding during the year was 3,782, or rather more than a seventeenth part of the whole force employed. As to the proportion of men constantly off duty from sickness, the average throughout the service, taking one day with another, was 3,436, or more than a nineteenth part of the entire force; in other words, the effective strength of the navy was at all times reduced by the aggregate crews of four or five ships of the line. To these facts and figures it may be added that the total number of cases of disease and injury was in the proportion of 1·4 each man in the service; and that the total number of days' sickness, spent either on board ship or in an hospital on shore, was such as to give about twenty days off duty per man in the course of the twelvemonth.

QUEEN'S COLLEGE, LIVERPOOL.—H. G. Morton, Esq., F.G.S., Honorary Secretary to the Liverpool Geological Society, has been appointed to the Lectureship on Geology and Palæontology; and Rev. R. Grant Brown to that on Arabic.

A NEW MEDICAL CHAIR IN PARIS.—The Minister of Public Instruction has just created at the Collége de France (a Government institution for the gratuitous teaching of the higher branches of science and literature) a chair of the History of Medicine. The course of lectures will commence early in April, and the professor appointed is the eminent philologist Daremberg.

THE CHALMERS HOSPITAL, EDINBURGH.—The Chalmers Hospital, a new and elegant building recently erected in Lauriston-place, has just been opened. The Directors, with a large number of Medical gentlemen, met on Saturday, the 12th inst., at the hospital. The building has been erected and founded in accordance with the will of the late Mr. Chalmers, plumber, in Edinburgh, who left 27,000*l.* for that purpose. The Directors have appointed Dr. A. H. Douglas, Acting Physician; Professor Miller, Acting Surgeon; and Dr. J. Clark Wilson, House Surgeon.

IMPROVEMENTS IN THE PARIS HOSPITALS.—The physicians attending the Hospital Cochin in Paris, having observed for some years past several cases of puerperal fever among the women there, and of which they have not been able to discover the cause, have determined to make a change in the arrangements. They have resolved that the wards devoted to female patients shall be occasionally closed; that is, when a ward shall have been occupied for several months, it shall be left vacant for some time, and exposed to a current of air. In order to assist in carrying out this arrangement the Municipal Council of Paris are about to build a large addition to the hospital. The new building is to contain four wards for women. Three only of them are to be occupied at a time, and one left vacant. Another improvement is about to be introduced into the Paris hospitals. A sitting room is to be attached to each dormitory, so that when a patient is sufficiently recovered to leave his bed he may have a place to read or to play at some innocent game, such as chess or draughts. Besides assisting in a perfect recovery of the convalescents, this plan will enable the patients confined to their beds to enjoy more quiet.

A FOREARM WRENCHED OFF DURING EFFORTS AT REDUCTION FOR DISLOCATION.—M. Adolphe Guérin related to the Paris Surgical Society, of which he is a member, the following extraordinary case. A woman aged sixty-three was admitted into the St. Louis Hospital for a luxation of the shoulder-joint of three months' standing. On examination, it was found that the humeral head was lying under the coracoid process; and, notwithstanding the long time the dislocation had existed, M. Guérin immediately gave directions for an attempt at reduction. Not having pulleys at hand, mere traction was tried first. Extension was made by a lac, first fixed above the elbow, and afterwards at the wrist. Counter-extension was employed as usual, and four very intelligent and steady pupils were desired to pull gently, steadily, and without jerking. Whilst traction was thus gradually being accomplished, a snapping noise was heard, and the forearm fell to the ground, the operators, rather terrified, being besprinkled with blood from a spouting artery. M. Guérin controlled the vessel immediately, applied a ligature, pared the wound, sawed off the protruding portion of the humerus, covered the wound with a lateral flap formed by the tearing process, and obtained a stump of the usual kind. By examining the forearm lying on the ground, it was found that the severance had taken place at the elbow, and the forearm seemed to have broken off like a dead bough breaks off from a tree. The bones and surrounding parts were soft and friable, and the muscles could be easily unravelled with the finger, like a clot of blood. All the textures, in short—vessels, nerves, muscles, and bone,—were discovered to be unsound, and the radius and ulna were snapped across by the moderate traction which the students had employed. Microscopic examination confirmed these views. M. Guérin considered that the alterations above alluded to were the result of the compression of the brachial plexus during the luxated state of the head of the humerus; and he thought that the practical lesson to be derived from this accident was, that surgeons having to treat luxations of three months' standing will do well to order tractions of a very moderate kind, so as to avoid so unpleasant an issue as the one just described. It seems to us that the *age* of the woman had a good deal to do with the result; nor can it be overlooked that the pulling of four persons at an aged patient's arm was in itself a procedure of some peril.

COMPULSORY VACCINATION.—Mr. E. S. Leete, Medical officer of the Newton district, has appealed to the Warrington Board of Guardians for the enforcement of the provisions of the Vaccination Act. Notwithstanding the prevalence of small-pox in the district, several parents have opposed the vaccination of their children. The Board have given directions to the registrar to proceed against the parties so offending.

TESTIMONIAL TO A SURGEON.—A testimonial, bearing the following inscription, has been presented to Edgar George Pottle, Esq., as a mark of esteem for his valuable services and kind attention to many cases of accidents and injuries which occurred during the progress of the main drainage works at Plaistow:—"Presented to Mr. Edgar G. Pottle by the surgeon, engineer, and managers of the North London Main Drainage, as a token of their high esteem and confidence, also for the satisfactory manner in which he performed the duties of assistant-surgeon to the above works."

DR. DUNCAN MACPHERSON AND THE MADRAS GOVERNMENT.—The Indian press, which has so frequently supported the members of our profession in their just claims on the Government, has recently commented in strong terms on the injustice recently inflicted on Dr. Macpherson. The *Madras Athenæum* thus briefly states the case: "Dr. Macpherson, who was promoted for distinguished services in 1858, proceeded to England on medical certificate in 1862, when he had before him, in the terms of the Royal Warrant of 1860, her Majesty's assurance that his appointment was secured to him until he should attain the age of sixty-five years. While he was absent, the Madras Government, though failing to procure the concurrence of the Governor-General, succeeded in gaining the acquiescence of the Home authorities to the limitation of the services of the Inspector-General to a period of five years. Yet, though they had the

power to reappoint him for a further term of five years, they did not do so, but actually dislodged him before he had completed his short five years' tenure of office. And notwithstanding a stringent dispatch from the Secretary of State Dr. Macpherson remains at present out of employ." In the *Gazette* of the 27th of January we read that "Inspector-General of Hospitals, Dr. Macpherson, is permitted to *reside* and draw his pay in the Mysore Centre, or Southern Division." The public are, therefore, deprived of the experience and knowledge his published werks prove him to possess.

THE KNIFE AND SAW VERSUS CONSTRICTING AND BREAKING. — Two Paris surgeons of reputation, Messrs. Maisonneuve and Chassaignac, seem to have bid adieu to the knife and saw, and taken to constricting of soft parts, and snapping of bone. The dread which some patients express at the usual surgical instruments is sometimes very great; but what would they say were they to know all the horrors accompanying the amputation of a limb by first breaking the bone, through the soft parts, by means of a *crusher*, and then dividing these parts with relays of chains and whip cord! M. Chassaignac has ridden his hobby so far as to perform lithotomy with his chain; and M. Maisonneuve has amputated the thigh by breaking and tearing. All these distressing proceedings are undertaken with a view of preventing hæmorrhage and purulent infection; but, in spite of twisting and snapping, the parts *do* bleed, and patients *do* die after the operations. It is with these methods as with all the theories of medicine which have from time to time been propounded: too much universality is attempted, and exaggeration spoils the good which moderation might have produced. 'La France Médicale' (of March 16th) states that M. Maisonneuve removed a tubercular testis by constricting skin and cord to separation. No bleeding ensued. When suppuration had begun, serrefines were used, and the patient did well. We beg nevertheless to say, that constriction of the strictures which compose the cord may act injuriously on parts within the abdomen. And we add that when a portion of the frame is removed, a little bleeding does no harm, if there is no special counter-indication. The same system, with hemp cord, was adopted for a cancer of the lip: three threads were passed through the base, and the three loops twisted until the tumour fell off. Here, again, no dressings were applied, and healing took place rapidly after suppuration.

THE PLYMOUTH PUBLIC DISPENSARY.—At the quarterly meeting of the Committee of the Plymouth Public Dispensary, on the motion of the Rev. J. Yonge, seconded by the Rev. J. Bliss, C. R. Prance, M.D., was elected one of the physicians to the Institution, in the room of Dr. Cookworthy, resigned.

GRATUITY TO A SURGEON. — At a meeting of the Governors of the Torbay Infirmary on Saturday last, a unanimous vote of thanks was passed to Dr. Woodman on his retirement from the duties of house-surgeon, and a purse of ten guineas presented to him, the funds of the institution not allowing them to make a larger grant.

PROPOSED INFIRMARY AT DONCASTER. — The movement for the new institution is proceeding most favourably. The only difficulty connected with it is that of finding an appropriate site; the one already in view being in many respects ill-adapted in the essential requisites for an hospital. The best sites are in the position of Mr. Forman, a gentleman to whom the noble example of Mr. Howard, of Stanley, in his gift of a plot of ground for a similar purpose at Burnley, might be presented for imitation.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAR. 30.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.

THURSDAY, MAR. 31.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; London Surgical Home for Diseases of Women, 2 p.m.

FRIDAY, APRIL 1.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, APRIL 2.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.

MONDAY, APRIL 4.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, APRIL 5.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Laryngoscopal Medication, or the Local Treatment of the Diseases of the Throat, Larynx, &c. By L. Elsberg, M.D. New York: W. Wood and Co.

On the Nature, Pathology, and Treatment of Puerperal Convulsions. By R. Hodges, M.D., F.R.C.S.I. London: John Churchill and Sons, New Burlington street.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

MEDICAL EDUCATION.—In reference to our remarks on Medical Education, condemnatory of the custom of paying the Examiners according to the number of successful candidates, we have been informed that at the University of St. Andrew's, since the year 1850, the Examiners have been paid the same fee for successful as for unsuccessful candidates.

AN INVALID.—Mr. Acton, 17 Queen Anne street, Cavendish square, W.

Dr. KIDD.—We regret our inability to publish the paper in consequence of its length, and the other urgent demands on our space.

Opodeldoc.—We shall feel obliged if any of our readers can inform us what is the etymology of this word, and when it was introduced.

A LATE MEMBER OF THE EXAMINING BOARD AT THE UNIVERSITY OF ST. ANDREW'S will find that we have noticed the subject of his letter.

THE HARVEIAN SOCIETY.—The Report of the meeting is inserted.

Dr. E.—The newspapers have been received, but for reasons already given, we think it inexpedient to allude any further to the subject.

Mr. O'D., *Limerick.*—The report of the trial is too long for insertion, and the points involved are of no public or professional importance.

Dr. C. J. P. will find that we have adopted his suggestion.

CHANGE OF NAME.—We are requested to state that Dr. Charles Jones, of Manchester square, has taken the additional name of Percival, as was announced in the 'Times' of the 10th inst.

Dr. HEATON.—We do not at present know of any person calculated to supply the vacancy, but we should recommend our correspondent to apply to the office of one of the Medical agents, either personally or by letter.

JOHN OF ST. ALBAN'S.—Will the new Act as contemplated by the "Medical Council," (if realised) be likely to prohibit chemists from compounding medicines; if so, such powers will go far beyond the Apothecaries' Act of 1815, that Act not being retrospective in its operation. Such an Act would ruin the chemists and druggists of this country, and such an Act of Parliament would operate against registered surgeons, if they did not happen to possess the Apothecaries' Hall certificate, and thus prohibit such parties from dispensing their own prescriptions, as well as those of legally-qualified physicians.

[It is not likely that any such measure will ever pass, but pure surgeons cannot, under the present law, dispense their prescriptions.—ED. MED. CIRCULAR.]

To the Editor of the Medical Circular.

SIR,—In consequence of the brief notice in your "Review of the Periodicals" of March 9, of a paper by Dr McClintock, I am induced to offer a few remarks on "missed labour;" it was

applied by Dr. Oldham to those cases in which the woman went on to her full time, but the child failed to be brought forth, owing to a want of parturient efforts. The waters in those cases are discharged at the expiration of the natural gestatory period, unless they have been so previous to it, and the fœtus is apparently dead at the time when labour should have come on. It is somewhat difficult to distinguish missed labour from extra-uterine pregnancy, and no doubt some of the cases supposed to be and published as belonging to the former, should be placed under the head of the latter.

There are about twenty well-authenticated instances of missed labour. The child sometimes remains in utero an almost incredible length of time beyond the usual period of gestation, and that too without the supervention of decomposition; in the instance adduced by Dr. Cheston, this period was protracted to fifty-two years, and yet "the body of the child was very firm and compact, as if condensed by great pressure; it seemed completely deprived of its fluids, and formed therefore a contrast to the juicy state of a body recently deprived of life; of blood either in a fluid or coagulated state or of that colour, which results from this fluid being contained in the vessels of a part there was not the slightest appearance." The cause of the non-putrefaction is the exclusion of air from the cavity in which the fœtus is enclosed.

In the following instances the period of protraction was:—3 months (Oldham); 8 months (Menzies); 16 months (McClintock); 17 months (Dewes); 2 years and a half (Montgomery); more than 3 years (Nebelins); 9 years (Schulz); 11 years (Vondorfer); 20 years (Caldwell); 40 years (Voigtel); 52 years (Cheston).

The discharge—when putrefaction has taken place—may be so intensely fœtid as to lead to the supposition that malignant uterine affection is present. The etiology of the occurrence is yet involved in obscurity.

One of the last recorded cases of this lesion is that mentioned by Dr. McClintock, in the 'Dublin Quarterly Journal of Medical Science,' Feb. 1864; we give the following abstract:—The patient, a large flabby woman of cachectic appearance, was forty-five years of age, and mother of many children; her last confinement had taken place fourteen months previous to her calling upon Dr. McClintock. Her condition on presenting herself was: *Great* impairment of the general health, owing—the patient considered—to the existence for some months of a constant profuse and intensely fœtid discharge per vaginam; there was not any hæmorrhage and but little pain. A globular tumour, in size equal to the uterus when four months gravid, was detected in the hypogastric region.

The os uteri was thickened and indurated, and on pressing the finger against it the fœtid discharge flowed freely and copiously away; these led to the inference that the affection was malignant. Examination with the *sound* demonstrated the presence in the uterus of some hard substance, evidently osseous or calcareous in its nature; examination with the finger passed well up the cervix and into the uterine cavity enabled several bony projections and surfaces to be made out. Having fully satisfied himself of the presence of the bones in the uterus, Dr. McClintock elicited from the patient this additional history respecting herself:—Twelve children had been born alive, a thirteenth was born dead, but at full time; conception again took place for the fourteenth and last time, and she went on well until the seventh month, when the fœtus died; gestation continued, and at the end of the ninth month labour pains set in, and discharge of blood and water supervened, nothing was born; five weeks subsequently severe pains resembling those of labour again occurred, and continued for two days without any cessation; they were attended with hæmorrhage, and on vaginal exploration a fœtal rib was found in the vagina; other bones entirely denuded of flesh came away at this time, and on various subsequent occasions fragments of bone were extruded. After dilatation of the os and cervix by means of a sponge tent, the patient was submitted to ten successive operations, at each of which more or less of the bony mass lodged in utero was removed. Symptoms of pyæmia, and death occurred after the tenth operation.

The treatment to be pursued in cases of missed labour is removal *as soon as possible* of the mass of corruption lying buried in the cavity of the womb; the os should be capable of admitting two fingers, and if not so previously to the time we may have selected for operation, it should be dilated by the sponge tent, or by one composed of sea tangle.

I am, &c.,

March, 1864. G. DE GORREQUER GRIFFITH.

Royal College of Physicians of LONDON.

TWO LECTURES ON THE LARYNGOSCOPE, will be delivered at the COLLEGE, PALL MALL EAST, by Dr. GEORGE JOHNSON, On Wednesday April 6th, and Friday, April 8th, at five o'clock P.M.

LECTURE I:—
THE METHOD OF USING THE INSTRUMENT, AND THE HISTORY OF ITS INVENTION.

LECTURE 2:—
ILLUSTRATIONS OF ITS VALUE IN THE DIAGNOSIS AND TREATMENT OF DISEASE,

(By order of the President.)

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible, or have altogether failed in effect. Imitations having arisen, be particular in the address.

Emperor Life and Fire Assurance SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to
EBENEZER CLARK, JUN., SEC.

Prize Medal, International, Exhibition, 1862.

F. R. Gustav Ernst, Orthopædic and ANATOMICAL MACHINIST, Manufacturer of Surgical Instruments, Elastic Bandages, &c. &c
19 Calthorpe street, Gray's-inn road, W.C.

DINNEFORD'S

Pure Fluid Magnesia, now perfect in purity and strength.

"Mr. Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal.' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared in a GRANULAR and EFFERVESCENT Condition the Constituents of the following MINERAL SPRINGS:—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT, &c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER:—
GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS:—
GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.
GRANULATED AND EFFERVESCING CITRATE OF QUININE.
GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON
PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON
MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.
143, NEW BOND STREET, LONDON.

James's Fever Powder, 4s. 6d. per bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all wholesale Druggists.

Leeches, Turkey Sponge, and all Kinds of Medical Herbs. Best and Cheapest at H. POTTER'S DEPOT. 65 FARRINGDON STREET, LONDON, E.C.

His New Priced Catalogue sent to any address on application. Established 1812.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By Robert Hunter Semple, M.D.,
Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 164.)

The Alterations in the Sounds of the Heart.—Having considered the nature and the causes of the healthy sounds of the heart, it is now necessary to explain the modifications which they undergo under the influence of disease. Remembering that the maximum of intensity of the first sound is immediately below and a little to the left of the nipple, and that of the second is a little higher above and to the right of the nipple, on the left side, and that these sounds diminish in intensity in proportion as they are distant from the præcordial region, till they are absent altogether in the right side and back of the chest:—the auscultator will be able to appreciate the abnormal conditions which the sounds present when disease is present. Even when there is an absence of morbid sounds, or murmurs, the healthy sounds may be altered in their situation, their extent, their intensity, their pitch, or their order of succession, and it is very essential to note these particulars, which sometimes accompany or help to characterise serious diseases of the heart, sometimes result from abnormal conditions of the blood, at other times are due to disturbed states of the nervous system, and occasionally are caused by morbid affections of different organs unconnected with the heart except in a physiological sense.

Thus, for instance, the sounds of the heart and the impulse which always accompanies the first sound, will be altered in their seat, and will be perceived above the points just indicated, in cases where the diaphragm is pushed upwards by flatulent distension of the abdomen or by ascites; and they are perceived on the right side to a greater or less extent in the well-known case where the heart is dislocated by a pleuritic effusion on the left side.

The extent to which the sounds will be heard will also vary very considerably, being sometimes confined to an unusually limited space over the præcordial region, and sometimes spread over the greater part of the front and even the back of the chest. The diminution in the extent to which the sounds are heard may depend upon the diminished size of the heart, or to the feebleness of its action, or to general weakness of the system, and this condition is almost always accompanied by a diminution in the impulse of the organ. On the other hand, the extent to which the sounds are heard, and the impulse felt, will often be very much increased by a number of circumstances, some of great pathological importance, and many of no great significance; and the Medical attendant must carefully examine, not only the sounds themselves, but all the concomitant circumstances of the case, in order to arrive at a correct conclusion. Thus, an increase in extent of the sounds of the heart may denote a dilatation of the organ, which, however, is usually accompanied by hypertrophy, and will present other more characteristic signs. Hence, except in rare instances, a mere increase in extent of the sounds without a corresponding increase of impulse, does not denote organic disease of the heart, and is usually indicative either of some peculiar condition of the nervous system, or of some disease in adjacent structures. Nothing, in fact, is more common, especially in thin persons, children, and women, than to find the sounds of the heart perceptible over a very considerable portion of the front of the chest, and yet there may be no organic disease, either of the heart, or of the lungs, or of any other structure. It is still more important, however, to recollect that in tuberculous disease of the lungs, or any other affection which consolidates those organs, the sounds of the heart will be heard over a very extensive space, because the condensed tissue will then act as a conductor of the sound. This is sometimes one of the earliest signs of pulmonary tuberculosis, and in not a few cases the heart has been pronounced to be diseased, when the real malady was in the lungs. It may, however, be observed that in such cases the dulness on percussion and the presence of bronchial breathing and bronchophony will throw light upon the diagnosis.

The intensity of the sounds of the heart also varies very considerably, being sometimes so loud as to be heard by the patient himself, or by persons at a distance, and sometimes so feeble that the ear can scarcely hear them at all when it is applied to the walls of the chest. In hypertrophy of the heart, the first sound is diminished and the impulse is increased; while in dilatation, the first sound is increased and the impulse is diminished; but as the usual morbid condition of enlargement of the heart is a combination of hypertrophy with dilatation, the sounds, and the impulse, and the extent to which they are perceived, are all increased in the same proportion. Again, the intensity of the sounds is diminished and their extent limited, and the impulse of the heart enfeebled, in those conditions of the organ where it is diminished in size and weakened in its action, or degenerated in its texture, or in other words, in that condition which is the opposite to hypertrophy with dilatation.

It was Laennec who first established the fact that the pulsations of the heart might sometimes be heard at a certain distance from the patients; in 1823, he observed this curious phenomenon in a young girl, and in 1824, he had two patients who exhibited it in a more remarkable degree than in his first case. He never heard the pulsations at a greater distance than from a foot and a half to two feet, and he convinced himself that the sound was that which accompanied the contraction of the ventricles, by their isochronism with the pulse at the wrist. Laennec states that out of more than twenty persons in whom he had heard the pulsations at distances varying from two inches to two feet, only about three or four were suffering from organic disease of the heart, all the rest presenting only nervous palpitation, and in all of them the phenomenon was transient. He, therefore, attaches to it no great pathological importance, but attempts to account for it by a theory which now seems absurd, and was never supported by any facts. He considered it to be due to the effusion of gas in the pericardium.

In a note appended to the last edition of his 'Traité d'Auscultation Médiate,' Laennec states that he observed this phenomenon in his own person, the sounds of the heart being perceptible to himself, and also to others who were in the room with him. He was ill at the time, and he suddenly felt and heard the contractions. He caused an attendant in the room to place her ear about six inches from the walls of the chest, and she heard them also very distinctly. The reason in his own case was evident, for he felt the region of the stomach distended with gas, and after an eructation the sounds were no longer perceptible at a distance.*

This observation is the more interesting, as it was written by Laennec on his death-bed, and was almost the last that he wrote. In a note appended to Laennec's work by Andral, the latter physician confirms the truth of Laennec's observation, and relates an interesting case in which he found the same phenomenon to exist. The patient was highly nervous and hysterical, and Andral heard the pulsations of the heart at a distance of several feet from the patient. The phenomenon was observed only during

* Laennec, 'Traité d'Auscultation Médiate,' vol. iii., p. 130.

certain hysterical or cataleptic fits, to which the patient was occasionally subject.

Since the time of Laennec, the sounds of the heart have been heard by numerous observers at a distance from the chest, but generally in a morbid condition of the heart or of the blood. Dr. Elliotson, who was one of the earliest investigators of the auscultatory phenomena of the heart, once heard a cooing murmur so loud that it was audible at the distance of nearly a foot from the patient. Dr. Hope states, that he once heard a sound of this character at the distance of two feet from the patient's chest.

Another curious circumstance, occasionally observed in relation to the sounds of the heart, is that instead of the ordinary double sound, there are three sounds, each systolic sound being repeated, the diastolic remaining single, or the diastolic sound being repeated, the systolic being single. In other cases there are four sounds, the systolic and diastolic being both doubled, and it is sometimes observed that only one sound is audible, which is always the first sound. When a triple sound exists, it is most frequently owing to a reduplication of the systolic sound. Dr. Bellingham † states that in two cases under his care where the first sound was doubled, he had the opportunity of examining the bodies after death, and he found the right ventricle much hypertrophied and dilated in both, and forming the apex of the heart; the left ventricle was normal in one and slightly dilated in the other, but the valves at the left side of the heart were sound in both cases, and no murmurs had been audible during life.

(To be continued.

HOSPITAL REPORTS.

KING'S COLLEGE.

Deficiency of the Anterior Wall of the Abdomen Remedied by Operation.

Mr. Wood operated on a boy in whom there existed a deficiency of the anterior abdominal wall from the umbilicus downwards, also of the anterior wall of the bladder and of the penis, as far as its bulbous portion. This kind of deformity is probably occasioned by want of proper development of the allantois.

The present condition of the parts was:—The lower portion of the abdomen was of the peculiar reddish tinge indicative of its being constantly moist with urine; the perinæum and upper and inner part of the thighs were in the same state; the penis was short, and almost hid beneath a mass of tissues, which stretched over it in a bridge-like manner, leaving, however, a space between their under surface and the shrunken organ. Immediately above this mass of tissues, which had been formed by Mr. Wood on the occasion of a previous operation, came the deficiency in the anterior walls of the abdomen and bladder, the cavity of the latter communicating externally, not alone through this deficiency, but also through the space lying underneath the mass of tissues to which reference has just been made.

The first step of the procedure was to pare a thin slice from the upper margin of the "mass of tissues," and the second was to map out from the left side of the abdomen by three incisions a somewhat parallelogram shaped piece of tegument; this part so mapped out was then dissected up from the subjacent tissues in order that it might fit to and cover-in the space in the pubic region; the dissection, especially toward the mesial line of the body, had to be carried on most carefully, lest the peritoneum should be endangered. A triangular-shaped piece of tissue was in the same manner taken up on the right side; the lines of incision, when taken together, were not unlike the letter *M*, placed with about the degree of obliquity here given. On examining the interior of the bladder, some phosphatic concretions were found in it, and were removed with the tip of the little finger, after which the viscus was well washed out with tepid water.

At the margin of the integument which had been brought down in the former operation, so as to fill up the lowermost gap in the deficient walls, the tissue of skin could be seen to have already began to assimilate itself to that of mucous membrane.

The left flap, having been freely dissected up and its inferior external angle having had a little piece removed from it, in order to allow the whole to fit more completely into the place intended for it, was doubled downwards upon itself, so that its cuticular aspect looked towards the interior of the bladder, and its raw bleeding surface outwards; in this position it was made fast to the bridge of tissues already formed by the previous operation; and it was also secured above to the margin of the gap in the abdomen, wire sutures being employed for the purpose.

The thighs were approximated, and the flap from the right side of the abdomen was then brought down upon that which had been laid over the bladder; the two raw surfaces were now in contact throughout, and were held together by means of the wire suture.

There remained now the two spaces from which the tegumentary tissues had been taken, and these Mr. Wood proceeded to treat by means of long needles and the twisted sutures; two needles being required in each wound for its closure, and a simple thread of suture being also put in at the lowermost part of each wound; strips of adhesive plaster, carried from one side of the abdomen to the other, and a few strips of wetted lint placed over them, all being then made fast by a perinæal bandage, completed the operation.

Mr. Wood mentioned that there are on record three successful cases of this kind of plastic operation.

Mr. Holmes, who in England has drawn so much attention to this subject, in the cases upon which he operated, took his flaps from above, having their roots also superiorly, the surfaces between them being vivified, so that more perfect union might be obtained. Unfortunately, in some of Mr. Holmes's cases, sloughing of the flaps ensued and frustrated the operation; one of the cases, however, was successful.

Professor Pankoast, of America, also takes a flap from the centre, and then brings his side flaps into the centre, where he unites them.

The causes of failure are sloughing of the flaps from want of proper arterial supply, or their death from urinous extravasation between their denuded surfaces. The plan adopted by Professor Pankoast and by Mr. Wood of putting one layer over another, is decidedly the best, because, even should the urine escape through the deficiency, it will not get between every part of the opposed surfaces, and adhesion must take place at least in some spots. The flaps must be sufficiently large; the under one to close in the vesical opening, and the upper to cover entirely the deeper flap; unless these conditions be obtained, there is very great probability of failure in the proceedings.

The great difficulties in the operation are, that the recti muscles are wide apart, and that the structures imposed upon the peritoneum are so thin that the greatest caution is absolutely necessary for the protection of that membrane.

If the sac of the peritoneum should be opened, the urine will pass into it, and the chances are then very much against the patient; as the testes are usually in such instances in the groin, we must likewise avoid opening the sac containing them.

The flaps will slough should their roots be too narrow, or their entire depth from the surface too slight.

Mr. Wood's operation differs in one very material point from that of Professor Pankoast; the former takes the greater part of his flap from below, that is, from the scrotal

† A treatise on 'Diseases of the Heart.' By O'B. Bellingham, M.D., F.R.C.S., p. 132.

tissues, the base of the flap being likewise below. The advantage of this is, that you avoid dividing the arteries as they run from below upwards, which you can scarcely do, if you reverse the order of taking up the flap; when the arteries are in this manner cut across, the flap is obliged to depend upon anastomosing vessels for its arterial supply, and is, therefore, insufficiently nourished.

It should be our great rule to have the root of the flap downwards.

A difficulty in effecting a complete cure sometimes presents itself; it arises from the impossibility in some instances of procuring a closure of the wound at the upper margin of the pubis; as a consequence of this want of closure a fistula forms, and that, too, of no very tractable form.

We must avoid having a strain upon the flaps or upon the tissues surrounding them; should there be any, we must remove the sutures which occasion it, otherwise our flaps will be destroyed. Cases of this malformation are by no means uncommon, but the proportionate number of cures effected by operation is—as shown above—very small indeed.

Of this operation, Mr. Erichsen speaks as follows in his 'Science and Art of Surgery:' "This malformation is incurable. Operations have been planned and performed with the view of closing in the exposed bladder by plastic procedures, but they have rarely proved successful, and have terminated in some instances in the patient's death; they do not, therefore, afford much encouragement for repetition. The patient should, therefore, wear a properly-constructed instrument to receive and collect the urine, consisting of a hollow shield strapped over the part, communicating by means of a tube with an India-rubber bottle, which may be attached along the inside of the thigh."

In cases like that under notice, the inner or mucous surface of the bladder is everted and protrudes through the deficiency in the abdominal wall; the tumour thus formed varies in its dimensions according to the natural size of the bladder, the laxity of its coats and the condition of the viscera behind it; it is exquisitely sensitive, of a bright red or scarlet colour, very vascular in appearance, is papillated, presents all the features of mucous membrane, and is seen to be covered with a mucus-like secretion, which is alkaline, and seems poured out expressly to protect the delicate lining of the organ.

Conical papillæ mark the situation where the ureters open into the bladder; there is one of these papillæ on each side of the mesian line of the inferior wall or floor of the bladder, and in each is an ovoid depression, not more in diameter, perhaps, than about a line.

The penis is short as though it were shrivelled up, and is generally implicated in the lesion, being affected with epispadias; the testes are drawn into the inguinal canals, and the scrotum, with the neighbouring parts, are in a raw condition owing to the urine being constantly poured over their surface; the scrotum is besides shrunken.

The ureters do not appear to be at all so sensitive as is the bladder.

These cases of extroversion of the bladder afford opportunities of studying various matters in connection with the action of the urinary system.

The first to which we shall allude is the manner of the passage of the urine from the ureter into the bladder:—The lower end of the ureter, immediately above its papilla-like projection, is perceived to become distended and the ovoid depression in the papilla is opened to the extent of two or three lines, revealing a drop of urine in its cavity, and at once explaining the cause of the distended appearance of the lower part of the tube and of the opening of its mouth; this drop falls into the bladder, and the ureter then, with an evident sphincteric action, closes itself, and in doing so increases the depth of the oval depression. These series of actions are performed about three times in every minute, and the drop let fall from the one ureter uniting with that from the other to form one large drop, trickles down to the floor of the bladder.

The quantity of urine is pretty uniform, but the amount discharged through one ureter varies not a little nor is their action simultaneous, but, on the contrary, it is irregularly alternating.

As would be anticipated, the recumbent posture is not favourable to the emptying of the kidneys, but on the person assuming the erect position after he has lain for a little time in the horizontal, the flow is both rapid and full, the fluid being projected downwards in a little stream, or else in large drops.

The urine when thus expelled from the kidneys, supposing the patient to be otherwise healthy, is acid, and has an average specific gravity of 1·25.

From experiments conducted with different medicinal preparations, it has been demonstrated that their rapidity of absorption is dependent upon the condition of the stomach at the time of their introduction into it; for in those instances where a full meal has been taken, the substances so introduced were not noticed in the urine until a much longer time had elapsed than in the cases where a light meal had been taken, or where fasting had been enjoined for some hours.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF
H. LETHEBY, M.B., M.A., PH.D., &c.,
FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. IX.

ACIDUM TANNICUM.—We have already had occasion to allude to the chemical constitution of tannic or gallo-tannic acid when speaking of gallic acid; and shall now confine ourselves to the process given for its extraction from gall-nuts. The British Pharmacopœia directs galls in coarse powder to be percolated with ether saturated with water. The liquid which passes into the receiver separates into two layers. The lighter upper layer, is ether containing in solution a very small quantity of tannic and gallic acid, and some colouring matter; the lower is a yellow syrupy liquid, consisting of tannic acid, ether, and water. The lighter liquid is separated, and the heavier is first concentrated over a water bath, and finally completely dried in a hot-air chamber, the temperature of which must not exceed 212° Gall-nuts thus treated yield from 35 to 40 per cent. of tannic acid.

No objection can be made to this process; but if the directions of the Pharmacopœia as to the drying of the product be explicitly followed, the tannic acid will not be obtained in the light vesicular state in which it is found in commerce. The drying is, in fact, the part of the process requiring peculiar management. When the heavier liquid has been evaporated almost to dryness over the water bath, it is usual to distribute it in small portions over glass plates, and the heat is applied above. In this way the lumps become puffed up as they dry.

The Pharmacopœia process, though very well adapted for procuring tannic acid in a small way, is not the process followed on the large scale. It is argued, however, that the Pharmacopœia is not meant to be a guide to manufacturers, and the processes given only pretend to be such as would

enable Medical men and pharmaceutists to prepare small quantities of medicines for themselves. This reasoning, perhaps, may justify the rejection of the simple method for obtaining the acid, which is given in the new American Pharmacopœia, and which is generally followed.

Powdered galls, first exposed to steam or to a damp atmosphere for some hours, are made into a paste with ether saturated with water. A pound of galls will take up about a pint of ether and four ounces of water; the ether and water must be well shaken together before they are mixed with the galls. The mass is well covered up, and allowed to stand for six hours; it is then placed in canvas bags, and submitted to pressure. A thick syrupy liquid is squeezed out of the mass, and the lower stratum is treated as in the previous process, and is dried in the same way. The galls may be completely exhausted by a second treatment, and the product amounts to 60 per cent.

It is unnecessary to say that the tannic acid obtained from gall-nuts by either of these processes is never pure. It always contains some gallic and ellagic acids; but as the Pharmacopœia seems to regard the presence of these as unimportant, we need not describe the rather complicated processes for the purification.

Tannic acid is a pale yellow powder, with a strongly astringent taste; it is sparingly soluble in ether, but readily soluble in rectified spirit and water. The aqueous solution precipitates gelatine, and strikes a bluish black colour with persalts of iron.* Its formula is C^{54} H^{22} O^{34}.

Acidum Tartaricum.—The British Pharmacopœia retains the Edinburgh process for making tartaric acid. It is a very good process, but manufacturers know of a better. The source of the acid is cream of tartar—the bitartrate, or, as it is now more correctly termed, the acid tartrate of potash, since tartaric acid being a bibasic acid, is in this case combined with only one equivalent of base. The first part of the process consists in adding carbonate of lime to a solution of the acid tartrate as long as effervescence is produced. In this way a precipitate of tartrate of lime is obtained, and neutral tartrate of potash remains in solution. Chloride of calcium is now added to decompose the latter, and thus the whole of the tartaric acid is thrown down in combination with lime.

The precipitated tartrate of lime is collected, washed, and then decomposed by means of diluted sulphuric acid, which takes the lime, and sets free the tartaric acid. The solution of the latter is filtered from the precipitated sulphate of lime, evaporated to a density of 1·21, and set aside for the acid to crystallise. The foregoing is a brief description of the Pharmacopœia process. Makers of tartaric acid on the large scale, usually start with *argol*, the impure acid tartrate of potash obtained in the making of wine. This is treated in several ways: among others, the following is given by Dr. Hofmann, in his "Report on Chemical Products and Processes," as the method employed at the works of M. Kestuer, at Thaun.

The crude tartar is dissolved in hydrochloric acid, which separates at once the greater part of the organic impurities and also some colouring matter insoluble in hydrochloric acid. The solution is then precipitated with lime, and the tartrate of lime thus obtained is decomposed by sulphuric acid as in the Pharmacopœia process. The crystallisation is effected in the usual way; but the first crystals of acid, obtained from crude tartar require to be re-dissolved and decolorised by animal charcoal.

Grape juice is, of course, the original source of all the commercial tartaric acid, but it is worthy of remark that the acid may be formed artificially. Liebig has found it among the products obtained by the action of nitric acid on sugar of milk; and Messrs. Perkin and Duppa observed that it was produced by the decomposition of bibromosuccinnic acid, when the silver salt of this acid was boiled with water; and, according to Schindler, it is formed from citric acid when lemon juice is kept for some time in bottles.

Tartaric acid, as we have said, is bibasic, a fact to be remembered when prescribing it with an alkali. Its formula is C_8 H_4 O_{10}, 2 H O = 150. Twenty grains will require for complete saturation the following amounts of alkaline carbonates:—

Bicarbonate of soda . .	22 grains.
Carbonate „ (crystals .	38 „
Bicarbonate of potash . .	27 „
Carbonate „ (B. P.) .	24 „

Tartaric acid crystallises in oblique rhombic prisms; it is freely soluble in water and in alcohol. A little acetate of potash added to either solution gives a white precipitate of acid tartrate of potash. It is sometimes contaminated with lime, which will be detected by oxalate of ammonia; and with sulphuric acid, which will cause a precipitate with chloride of barium.

* It is much employed in medicine as an astringent, especially in the form of an injection; but it may also be administered internally.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 22nd, 1864.

Mr. Partridge, President.

A paper was read by Chas. H. Moore, Esq., F.R.C.S.,

ON A NEW METHOD OF PROCURING THE CONSOLIDATION OF FIBRIN IN CERTAIN INCURABLE ANEURISMS,

WITH THE

REPORT OF A CASE IN WHICH AN ANEURISM OF THE ASCENDING AORTA WAS TREATED BY THE INSERTION OF WIRE, BY CHARLES MURCHISON, M.D., F.R.C.P.

In this joint paper the theory of the operation was first described by Mr. Moore. Dr. Murchison furnished the report of the case, with medical comments upon it. For the surgical remarks, Mr. Moore was alone responsible.

In February, 1863, Mr. Moore had been led to review the conditions of such aneurisms as could not be surgically treated through the artery, and had devised a method of producing consolidation of them in accordance with the mode of their natural cure.

The principles involved in this method were—1, that large aneurisms can only be benefited by the deposition of fibrin within them; 2, that the natural means of obtaining fibrin from the blood are inadequate, because it can only settle in layers on the wall; 3, that in the central part o an aneurism

there is a large quantity of blood with fibrin ready to collect on any apt material; 4, that fibrin may be elicited from arterial blood by exposing a foreign body in it. Two cases were quoted in which this had occurred: one, an instance in which gangrene of the leg had resulted from plugging of the arteries by fibrin detached from a needle in the left ventriele; the other, that of a sailor, who died three days after being shot, and in the interior of whose ascending aorta was a bullet imbedded in fibrin.

The foreign body which, according to our present knowledge, would produce least irritation was wire. If a large quantity were coiled in aneurism, it would attract fibrin, as the twigs do in whipping freshly drawn blood, support the mass which it entangled, and lead to the cavity of the aneurism being eventually filled. The wire might be passed in through a small canula, with care not to leave the last end in the minute wound, and not to direct a coil into the orifice of the artery.

Only a sacculated aneurism could be so treated, not one which had two orifices, since fragments of fibrin would be broken off by the force of the current. Brasdor's operation might be previously required in some parts. This danger might be incurred in a sacculated aneurism also, if wire enough were not introduced, because of the large intervals which would be left between the few coils of wire. The wire would remain in the solidified aneurism, and be harmless.

Mr. Moore then described the operation by which the foregoing proposal might be carried out.

Report of a Case of Saccular Aneurism of the Ascending Aorta projecting through the Anterior Wall of the Left Side of the Chest.

Daniel D——, aged twenty-seven, became a patient at the Middlesex Hospital, under Dr. Murchison, on Nov. 10th, 1863. Eight years before, he began to suffer from palpitations and dyspnœa, and after some months he had an attack of hæmoptysis. The hæmoptysis recurred at intervals, and in Nov. 1862, he first noticed a pulsating swelling in front of the chest to the left of the sternum. This increased with considerable rapidity, and the patient now became subject to severe attacks of angina pectoris. At the time he first came under observation, the tumour was situated in the angle formed by the left clavicle and the left margin of the sternum; it measured 10 inches in circumference at its base, and projected about 2 inches from the wall of the chest; its surface was rounded, and tolerably uniform, except at the upper part, where there was a tendency to point. Over the whole surface of the tumour distinct pulsation could be felt, each beat corresponding to the impulse of the heart. Nothing resembling an aneurismal bellows-murmur could be heard; but both cardiac sounds, and particularly the second, were louder over the tumour than at the base of the heart. There was dulness on percussion to the right of the tumour, over a space measuring 2 inches transversely, and 3 inches from above downwards. The apex of the heart could be felt beating between the fifth and sixth ribs. The cardiac dulness was slightly increased, but the sounds heard on auscultation were normal. There was no inequality of the arterial pulse on the two sides of the body. The voice was normal. The patient had an occasional cough, and expectorated a viscid muco-purulent matter, but there was nothing peculiar in the character of the cough. Over the whole of the left side of the chest there was comparative dulness on percussion, with coarse, at some places tubular, breathing, and subcrepitant râle. On the right side of the chest the percussion was clear and the breathing puerile. The appetite and digestion were good, and the bowels regular. There was no dysphagia, and no pain or tenderness at any part of the spine. The pupils were of normal and equal size. On Nov. 20th, and again on Dec. 28th, the urine was ascertained to be free from albumen.

After the patient was admitted into the hospital, on the 20th of November, the attacks of angina almost entirely ceased. The pulse varied from 104 to 116 when the patient sat up, but would fall to below 100 when he lay down. The size of the tumour continued to increase, until, on the morning of Jan. 7th, 1864, it measured 16¾ inches at its base, and projected 2⅔ inches from the wall of the chest. The tendency to point at its upper part became more decided, and the integuments at this part were much attenuated, and assumed a dusky red discoloration, while occasionally they were the seat of pricking pains, and were slightly tender. These changes were most marked during the last week of December and the first week of January. The patient's general health notwithstanding did not suffer. He ate and drank well; he got up daily, and walked about the ward. On the evening of January 6th he played a game of draughts with another patient, and on the following morning he was up and walking about as usual.

Early in January it became obvious that the bursting of the aneurism through the integuments could not be long delayed. It was accordingly resolved to recommend to the patient Mr. Moore's proposed operation. During the month of December this operation had been carefully considered, but it was then deemed unadvisable to have recourse to it. It was now explained to the patient that the procedure in question offered some chance of prolonging his life, although in itself it was not free from danger. The patient at once assented, and the operation was performed on Jan. 7th, at half-past one p.m.

The operation consisted in the introduction of a quantity of fine iron wire into the aneurism, with the object of inducing coagulation. A small pointed canula was inserted into the tumour, and the wire was passed in through this without difficulty. The operation occupied one hour, and the quantity of wire introduced was twenty-six yards. It gave rise to no pain or inconvenience excepting a slight and transient feeling of faintness. The quantity of blood lost did not exceed half a fluid ounce.

The immediate effects of the operation were a reduction of the pulse from 116 to 92, an almost complete cessation of the pulsation in the tumour, and a diminution in its size. Immediately before the operation, the circumference of its base was 16¾ inches; at the close of the operation it was 16 inches. These changes began to be noticed soon after the commencement of the operation, and became more marked as it was proceeded with. At a quarter past eleven p.m. the patient was asleep, and his pulse was only 78. He slept comfortably during the night, and had no bad symptom until the following morning.

On Jan. 8th, at nine a.m., the patient was seized with a fit of rigors lasting three quarters of an hour, and followed by great pain in the back of the neck and some pain in the tumour. At one p.m. the pulse had risen to 144, and was full and bounding. The action of the heart was tumultuous, and all the arteries of the body could be felt throbbing with considerable force, but there was no difference in the force or volume of the beat on the two sides of the body. The patient complained of great pain in the tumour when he moved. The tumour was already somewhat larger than before the operation, and the dusky discoloration was of a deeper tint. There was intense thirst and great restlessness; the skin was dry and very hot; and the respirations were 40. At twenty minutes past one p.m. the patient was bled to the extent of eighteen ounces, and at half-past three p.m. twelve ounces more blood were abstracted. After the second bleeding twenty minims of Battley's sedative solution were administered.

From these measures the patient derived temporary relief, but he had a restless night, and at half-past six a.m. of the following morning (Jan. 9th) he had a second attack of rigors. At one p.m. he had a third attack. At half-past one he was in great distress, owing to pain in the tumour and at the back of the neck. The tumour was extremely tense and decidedly tender, particularly at its upper part. Its circumference at the base measured 1¾ inches more than before the operation. Distinct pulsation could be felt again at its upper part. The pulse was 136 and soft; the action of the heart was less tumultuous, and there was no abnormal cardiac sound. Large and repeated doses of opium and digitalis were now commenced. At half-past ten p.m. the pulse had fallen to 126, but the patient complained of being afraid to cough on account of a severe jerking pain in the tumour, which the effort to do so always induced.

On Jan. 10th, at ten a.m., the patient had taken seventy-three minims of tincture of digitalis, and the equivalent of almost ten grains of opium, during the preceding twenty-one hours, and the result was, that he was in less pain, the pulse had fallen to 104, and the tumour was slightly reduced in size, its circumference being half an inch less than on the preceding day. At half-past seven p.m., however, he was seized with a severe burning pain in the tumour, and a feeling of tightness as if it were going to burst. The tumour was larger and more tense than ever; the pulse rose to 132; the heart's action was again more impulsive, and there was intense thirst. To-day it was noted for the first time that the pulses in the right temporal and radial arteries were slightly fuller than in the corresponding vessels on the left side.

Opium in large and repeated doses, along with digitalis, was persisted with. In the course of two days and a half (commencing on Jan. 9th), as much as the equivalent of twenty-seven grains of opium was administered. The treatment, however, failed to give relief. The tumour increased rapidly in size, and on the 11th distinct pulsation could be felt at several parts of its surface. The radial pulse was 128, small and compressible, and still fuller on the right side. The beat of the right anterior tibial artery was also decidedly fuller and stronger than that of the left. The cardiac impulse was extremely feeble. The respirations were performed chiefly by the diaphragm and the muscles on the right side of the chest; the left side of the chest was almost motionless. The whole of the left side of the chest in front, unoccupied by the tumour, was dull on percussion, and no respiratory sound could be heard on this side, except immediately below the clavicle. Brandy and other stimulants were now given, but without any decided result.

On the morning ot the 12th the patient was evidently sinking. The pulse was about 136, but was so weak as to be counted with difficulty. The circumference of the tumour at its base was now 3½ inches more than before the operation, and the urine passed during the night was found to be loaded with albumen. At eleven a.m., four and twenty hours and a half after the operation, the man died.

An autopsy was performed a few hours after death. The walls of the external tumour were formed by the integuments and fibres of the pectoral muscle, infiltrated with serum. They were nowhere less than a quarter of an inch in thickness. The skin covering a great part of the tumour presented a deep livid hue. The interior of the tumour was filled, for the most part, with a fibrinous coagulum, enveloping and imbedded in the coils of wire, and firmly adherent to the surrounding walls. The rest of the cavity contained fluid black blood. The interior of the outer tumour was nowhere lined with a prolongation of the arterial coats; but it communicated with the proper aneurismal sac within the chest by two large openings in the first and second left intercostal spaces, the intervening rib being bare and eroded, and at one place broken through. The aneurismal tumour within the chest was about the size of a man's fist. It lay immediately behind the sternum; it encroached slightly upon the upper lobe of the left lung, and inferiorly it rested upon the right auricle. It was partially filled with a fibrinous coagulum, which was continuous with that in the outer tumour, and was adherent at one part over a space measuring about one-third of an inch in diameter. It communicated by a circular opening, scarcely so large as a sixpence, with the ascending aorta. Through this opening a clot projected from the aneurism into the vessel, and extended downwards into the heart, and upwards into the arch. The greater part of this clot was evidently of post-mortem date; but part of it, close to the opening, was pale, firm, and laminated. There was considerable atheroma of the coats of the thoracic aorta. The pericardium contained about eight ounces of turbid serum, and its opposed surfaces were coated with a thin layer of recent lymph. The upper part of the parietal pericardium presented a patch of livid discoloration, about the size of a florin; and at the centre of this patch the cavity of the pericardium was merely separated from that of the aneurism by a delicate membrane. It was at this part of the aneurism that the coagulum was adherent. The heart was slightly hypertrophied. Its valves and muscular tissue, and likewise the coronary arteries, were healthy. The left lung was everywhere firmly adherent, and its pleura much thickened. On section, numerous cavities were observed, evidently resulting from dilatations of the bronchial tubes. In the intervening spaces a firm fibrous tissue took the place of the normal vesicular structure. The right lung was for the most part healthy. Both kidneys contained a number of circumscribed abscesses, varying in size up to that of a small pea. A cluster of six of these small abscesses was found at the apex of the left kidney. In the cortical substance of both kidneys a number of patches of yellowish deposit, of a large size, but less defined outline, were also observed. On microscopical examination, this appearance appeared to be due to the presence of a granular exudation deposited between the uriniferous tubes. The liver was large and fatty The other parts of the body could not be examined.

After recording the history and post-mortem appearances of the case, Dr. Murchison enumerated some of the more important features of clinical interest, independent of the operation, which it presented.

In his concluding remarks, Mr. Moore referred first to the circumstances of the operation, and to its early effects, which were highly satisfactory. So much fibrin appeared to have collected at the end of an hour that the pulsation of the tumour and its sharp second stroke were no longer perceptible; the aneurism had much diminished in size; the pulse, which, notwithstanding medicines, had beat 112 for weeks previously, and was 120 before the operation, had fallen to 92, and at night was about 80. This unlooked for abundance of the fibrin accumulated not by an inflammatory, but by a mechanical process, was an unprecedented circumstance. Its effects could not be foretold. It appeared to have caused local inflammation and the rigors, with great acceleration of the pulse. No aneurism could long resist such a pulse. Death had probably resulted from acute pericarditis, which was induced, not by continuity with the inflammation outside the chest, since neither the inner aneurism nor the pleuræ were inflamed, but incidentally by the imminent bursting of the intra-thoracic aneurism into the pericardium. No fragments of the clot of fibrin, large enough to be detected by the naked eye, had been detached, but microscopic portions were supposed to have existed in the kidneys. Neither the old nor the recent disease of the kidneys had actually caused death, which was due to the changes about the chest, and was, through the pericarditis, an indirect and not inevitable consequence of the operation. No coil of wire had passed through the opening of the aneurism.

Three facts appeared to Mr. Moore to justify a repetition of the operation, or of some modification of it:—1. The separation of fibrin upon the foreign body, and its rapid deposition. 2. The exemption of the inner aneurism from inflammation, probably to be accounted for by its possessing a lining membrane, which the outer cavity had not. 3. The firm adhesion of the clot to the wall.

Not having yet thought of a more suitable foreign body than wire, he had but two modifications of the operation to suggest: 1. The introduction of a smaller quantity. The objections to this had already been pointed out. 2. The use of slender needles as temporary means of procuring the consolidation of the fibrin. The safety of this must depend on the number of needles which might be inserted, the gentleness with which they should be withdrawn, and the period at which fibrin so procured should acquire a sufficiently firm attachment to the wall of the aneurism to allow of the artificial support of the needles being dispensed with.

The President inquired if the reading of Mr. Moore's concluding remarks was essential, the time of the Society's meeting having nearly expired.

Mr. Moore said he should be happy to spare the Society from the reading of his remarks in full, and very briefly recounted their principal points. In answer to another question by the President, Mr. Moore observed that the method of treatment which he had suggested differed from that by galvano-puncture, in that the latter caused consolidation of the entire mass of the blood between the points o-

the needles, which was objectionable, as not being permanent and curative; whilst the former elicited fibrin from the blood, which was the material of natural cure.

Dr. Copland remarked that the case was one of very great importance, but it proved nothing in favour of the mode employed for coagulating the blood in an aneurismal tumour. It would be observed, however, that the wire had not been introduced into the inner aneurism, and this to some extent might explain the failure of the proceeding. Moreover, he thought that no such plan could supersede the treatment of aneurismal tumours by diet and medicine, which he believed in most instances would be found more effectual in coagulating the blood. The case before the Society might, however, serve as a guide to surgeons for the future; but the proceeding should not be resorted to so long as diet and medicine could afford benefit.

Mr. Hilton wished to ask Dr. Murchison what he considered to have been the cause of the patient's death.

Dr. Murchison stated, in reply, that several causes had, in his opinion, contributed to the fatal termination. In the first place, he was inclined to put the contamination of the blood with inflammatory products derived from the tumour, giving rise to pyæmia and embolism. The purulent deposits found in the kidneys left no doubt as to the existence of pyæmia. These deposits had been carefully examined microscopically by himself and by Dr. Cayley (the pathologist to the Middlesex Hospital), and had been found to present all the characters of pyæmic abscesses. It was true that they were small, the largest being about the size of a small pea; but this circumstance was at once accounted for by the short time that the patient had survived the supervention of the symptoms of pyæmia. An important observation had been made in this case on the third and fourth days after the operation—namely, a very appreciable difference in the force and volume of the arterial pulse on the two sides of the body. This condition had not existed previously, and was not accounted for by the anatomical relations of the aneurismal tumour. No opportunity had been afforded of examining the arteries of the limbs after death, but the observation referred to, taken in connection with another morbid appearance found in the kidneys—namely, that of extensive inter-tubular deposit of a recent nature—led him to infer that embolism was one of the results of the operation. An observation had been made in the case which seemed to clinch, as it were, the development of these lesions found in the kidneys at a date posterior to the operation. Before the operation the urine had been free from albumen, but the urine passed on the day before death had been loaded with albumen. It was worthy of remark, that the anatomical characters of the aneurism were less favourable to the contamination of the blood with fibrinous flakes and inflammatory products than they would probably be in most aneurisms where the operation would be thought of. The orifice of communication with the aorta was small—not so large as a sixpence; and the whole of the proper sac of the aneurism within the chest had been interposed between the aorta and the external tumour, into which alone the wire had been introduced. Nevertheless, the blood had become contaminated. With regard to the pericarditis, it was a subject for speculation how far it was pyæmic in its origin, or whether it was due to a propagation by continuity of the inflammatory process from the sac of the aneurism, or resulted from the threatened bursting of the aneurism into the pericardium. The last explanation might be the true one; but while it was uncertain if the bursting of an aneurism into the pericardium was usually preceded by pericarditis, there could be no doubt that the pyæmia existing in this case would predispose strongly to pericarditis excited by any cause; and the fact that the pyrexia was ushered in with repeated attacks of severe rigors indicated that the pyæmia, rather than the pericarditis, was the first link in the chain of morbid events. Moreover, it was probable that the pointing of the aneurism in the direction of the pericardium was determined by the operation. Although an aneurism of the thoracic aorta often burst spontaneously into the pericardium, it was well known that this was a very rare event when there was an external tumour. The condition of the circulation on the day after the operation—a full, bounding pulse of 144—was extremely favourable to the giving way of a weak portion of the aneurismal sac. The causes of death, then, appeared to be pyæmia and pericarditis supervening on the operation.

Mr. Fergusson regretted that this case had been detailed with so much unnecessary minuteness, thereby occupying so much time that there was no opportunity of discussing it. It should have been condensed into one-fourth of the space which it occupied. (Hear.) The case, however, was one of great interest, and the Society must feel grateful to Mr. Moore and Dr. Murchison for the description of a case and of a mode of proceeding never before put into practice on the living body. He regretted that the experiment had not been carried out to its full extent, the wire not having been introduced into the aneurism proper, so as to produce a more direct influence of the heart's action on the blood. He considered the proceeding would be justifiable in cases similar to the one related, and in those aneurismal tumours of a more surgical character in which the mode of treatment to be pursued did not clearly suggest itself to the surgeon. The plan of passing wires and needles into aneurismal tumours had been suggested as much as thirty years ago; but he had never heard that it had been actually carried into practice, until the present case.

Mr. Moore, in reply to the observations of Dr. Copland and Mr. Fergusson, said that in the performance of the operation he had taken particular care not to introduce any of the wire into the inner aneurism, both because he had considered it essential to keep the distribution of it within that cavity which he had explored with the probe, while of the inner aneurism, and of what might become of the wire in it, he knew nothing; and also because, had the patient survived and required it, the treatment of the inner aneurism might have been the subject of subsequent consideration. He bowed to the opinion enunciated by Dr. Copland, that no aneurism should be submitted to this treatment so long as medical and dietetic measures were of service; and he should not think of recommending or adopting it except when these measures had lost their beneficial effect on the aneurism. Beyond those circumstances of the case which appeared to his colleague, Dr. Murchison, to have occasioned the fatal issue, he ventured to call attention to one other which he thought to be the most important and the starting-point of them all—namely, the very large mass of fibrin which had collected through mechanical means in the aneurism. To it he attributed both the local and the constitutional excitement which had commenced on the morning after the operation, and had, he believed, caused the pericarditis and the death. The main question before the Society of course was the prospect of advantage which this case held out from a repetition of the operation, or of a modification of it. He had come to the conclusion that the fatal issue was not an essential inevitable result of the operation, and that cases might occur in which it would prolong life. The first effect of the insertion of the wire had been very surprising, the pulsation of the aneurism and the peculiar sharp second stroke having become imperceptible at the end of an hour. This fact implied that the same effect might be produced in a little longer time with a smaller quantity of wire than had been used in the present case, and that that portion of it which had been inserted with difficulty might have been dispensed with. He did not wish, however, to be supposed to be laying down a positive rule for the treatment of other and perhaps dissimilar cases. The grounds on which the operation was based were all of them facts previously known, and familiar to all the Fellows present, whom he considered equally capable with himself of forming an opinion, and of contributing to avert the causes of the failure of the proceeding in the present case.

Some discussion subsequently took place respecting the reading of very long papers *in extenso*, and some irregularities in the manner in which papers were forwarded to the Society. The matter will probably come before the Council.

THE MEDICAL CIRCULAR.

WEDNESDAY, APRIL 6, 1864.

MEDICAL EDUCATION IN ENGLAND.

In our former articles on the subject of Medical education, we have addressed ourselves to readers in all parts of the three kingdoms of which our country consists, and in the remarks we have made, we have alluded to Medical education as a whole, and not as it was carried out in any one division of the empire. From the width of our scope and the general nature of our observations, and from the studied caution we have maintained in avoiding any allusion to individual cases, we have unfortunately fallen into the dilemma of having our strictures misappropriated by quarters in which they were never intended to apply, and of calling forth reclamations from institutions which we never intended to censure. One of the causes which induced us to enter upon the question of Medical education was the extraordinary pamphlet on the subject published by Professor Syme ; and one of our chief objections to the sentiments it expressed was that they were ludicrously inappropriate to the state of affairs in England and Ireland, however much they might be applicable (though still in a very limited sense) to one of the Universities of Scotland. We feared that the notions entertained by Mr. Syme might, from the natural respect due to his position in Edinburgh, be misconstrued as conveying the views and wishes of the Profession, and we have laboured, and we believe not altogether in vain, to disabuse the public on the subject. Some of our contemporaries have handled the same topic, but the writers have committed pretty much the same error as Mr. Syme in one respect, namely, that they have examined the question only in a partial light, as seen at the school or in the province where they are themselves established.

It is time, however, to descend from generals to particulars, and as England is certainly the largest and most populous division of the United Kingdom, it is only fair to devote an article to the state of Medical education as it exists in our own part of the nation ; and without any undue bias on the score of nationality, we think we may affirm that things are not so bad with us as some writers assume them to be. In a pamphlet which has just reached us "On the Present System of Medical Education in England," by Mr. G. W. CALLENDER, Assistant-Surgeon to St. Bartholomew's Hospital, the subject is very ably and temperately handled, and we are the more inclined to commend the opinions expressed by Mr. Callender as they entirely coincide with our own.

It will be recollected that among the faults of the present system commented upon by Mr. Syme was the enormous number of lectures which it was alleged the Medical student was bound or expected to attend, and other writers have indorsed the imaginary views which he expressed. We do not in the slighest degree impute wilful exaggeration or misrepresentation to Mr. Syme, but we distinctly accuse him of allowing himself to utter statements which are unsupported by sufficient evidence, and of supposing that the system he deprecates is really in operation throughout the United Kingdom. We may even offer an apology, or rather a justification, for the University of Edinburgh, in requiring attendance on a somewhat disproportionately large number of lectures by different professors, because that institution has always maintained a very high character as a school of Medicine, and the courses delivered there are probably more ample than those conducted at inferior schools. But Mr. Syme asserts that the British student of Medicine in general is overwhelmed by a multitude of lectures, and we have proved that such is not the case in our leading article of March 16.

Mr. Callender, who derives his experience from the largest of our Metropolitan Hospitals, confirms, and, indeed, more than confirms, the statement we then made. He shows that the time actually occupied by the lectures at St. Bartholomew's amounts *to two hours daily*, a period which is utterly insignificant when compared with the length of the day, or with the time expended in learning any art or science whatever. It is true, indeed, as we ourselves remarked, that some people object to lectures altogether as means of instruction, but then it is incumbent on such objectors to invent some other plan to supply their place.

Having thus shown how small a space of the twenty-four hours was really devoted to lectures, we pointed out that ample time was left for practical study, and here again we are completely confirmed by the testimony of Mr. Callender. He tells us that the courses of Anatomy, of General Anatomy and Physiology, and of Chemistry, during the first winter session at St. Bartholomew's, occupy exactly twelve hours of the student's time in each week : but that Practical Anatomy, that is to say, learning the bones and dissecting the various parts of the body under the superintendence of the demonstrators, occupies three hours daily. In addition to these exercises, it is the habit of the teachers of the school to require students during their first winter session to attend the surgical practice of the hospital for one or two hours daily, in order to render them familiar with the work in the wards, with the out-patient department, and with the post-mortem examinations, and for the purpose of cultivating a general acquaintance with surgical nomenclature, and with the appearances presented by accidents and diseases. Thus seven hours a day are apportioned to study, but only *two* for lectures, and the rest to Practical Anatomy and Hospital Practice. During the summer session, Botany, Materia Medica, and Practical Chemistry, involve an average daily attendance of *an hour and three-quarters*, but as the lectures on these subjects are concluded each day by noon-time, the rest of the day is left free for attendance on the practice of Surgery, and on the Medical wards and Medical out-patient department. During the second, third, and fourth winter sessions, a routine of pretty much the same character is pursued, the lecturing element being, in fact, entirely

subordinate to the practical; but to pursue the subject as sketched out by Mr. Callender, would be little more than to repeat the words of our own article, to which we have alluded.

We cannot help adverting in terms of the highest approbation to one of the features in the educational system pursued at St. Bartholomew's, namely, that there is provision each year in the wards and out-patient department for *one hundred and four clinical clerks*, and for *one hundred and twelve dressers*, each pupil remaining in office for three months at least, in either department, and having under his charge for that time, whilst on duty in the wards, the occupants of fifteen medical, or twenty surgical beds. We advert the more readily to this most valuable and excellent arrangement, because it is not very many years ago when such offices at our large hospitals could be procured only by money, and were altogether inaccessible to the great bulk of the students.

Mr. Callender, in the case of the students of St. Bartholomew's, rather indignantly repudiates the idea that they ever avail themselves of the perverted system of teaching, which goes by the name of *grinding*, and he gives a very high character for industry and attention to the students now attending at that great institution. We are delighted to learn that such is the case, and we hope that the students at all the other metropolitan schools will follow the example so admirably set them. The fact is, as we understand from Mr. Callender, that the best features of the grinding system are retained at his school, while its abuses are rejected, and that the demonstrators and tutors are so diligent in their duties as to render it unnecessary for the students to seek for tutorial assistance outside the walls of the building. This gratifying statement entirely carries out our opinion, that if the duties now performed by the grinders were ably and honestly performed by intra-academical lecturers and tutors, from *the commencement of the student's career*, the grinding system, thus conducted, would become one of the greatest boons to the student of medicine, instead of being, as we fear it too often is at present, a mere refuge for the destitute, and the last hope of the idler.

In connexion with this subject, we may state that the whole question of Medical Education was discussed at a late meeting of the Edinburgh Medico-Chirurgical Society, when Dr. Andrew Wood, who was the chief speaker, laid down a series of propositions, as heads of an improved plan of Medical Education. The following are his suggestions, in his own words, and we affirm, without fear of contradiction, that they *have all been adopted in London*, except the class-examinations, which, although strongly recommended, no authority as yet has power to enforce.

"Make," says Dr. Wood, "the preliminary studies and examinations in truth preliminary. For this purpose raise the age of commencing strictly professional study to 18; prune the professional course so that the student may have fewer courses of lectures to attend, and fewer lectures in each course; re-arrange the sessions; make class-examinations imperative on teachers and students; see that ample time is left to the student for reading and reflection, and that his course of reading is properly directed; see that he has ample time and opportunity to avail himself of practical instruction in the dissecting-room, in the wards of the hospital, at the dispensary, in the laboratory; see that, while the class-examinations be as minute and searching upon all points connected with the subjects taught as may be desirable, the final examinations be chiefly based upon the requirements of practice, and be directed to ascertain whether the student retains that knowledge which he ought to retain, and without which he cannot practise safely; see that a distinction, as is right, be made between the curriculum and examinations for a simple license to practise, and those for a license to practise accompanied with a title of honour, such as the degree of an university."

SUMMARY OF THE WEEK.

THE PROPOSED LEGISLATION FOR CHEMISTS AND DRUGGISTS.

We have already announced that the Branch Medical Council for England have decided that in their opinion it is not expedient at present to apply to Parliament for any amendment in the Medical Act; and thus, among other proposed novelties, the scheme of legislating for the Chemists and Druggists will probably fall to the ground, so far as the Medical Council is concerned. But in the meantime, the Chemists and Druggists themselves are stirring in the matter, and whether from the fear of legislation being pressed upon them, or from a desire to improve their status, are joining the Pharmaceutical Society in preparing the heads of a Bill to be presented to Parliament. The Society itself is not taking any very active steps, from the natural fear of defeat in case it should propose any plan which might be suspected of favouring exclusive interest, but it is rather yielding to the pressure of the Pharmaceutical practitioners out of the pale of the Society, in devising a measure which may give satisfaction to all parties. On the 17th of March, a Special General Meeting was held at the Pharmaceutical Society for the purpose of considering the propriety of asking for legislative interference, and the following heads of a Bill were proposed for consideration:

"After the 1st of January, 1865, no person to keep open shop for dispensing the prescriptions of duly qualified Medical practitioners unless registered as a Pharmaceutical Chemist under the Pharmacy Act, or as a Chemist and Druggist under this Act. Examination established for all who commence business after this date.

"Examiners under Pharmacy Act to be the Examiners under this Act.

"Registrar under Pharmacy Act to be Registrar under this Act.

"Chemists and Druggists in business in Great Britain before 1st Jannary, 1865, entitled to be registered as Chemists and Druggists, on payment of a fee not exceeding one guinea, and saving to them all their existing rights.

"Assistants and Associates under Pharmacy Act, who have passed Minor Examination, to be registered as Chemists and Druggists on commencing business.

"Council of Pharmaceutical Society to make orders for regulating Registers to be kept.

"Duty of Registrar to make and keep correct Register.

"Evidence of qualification to be given before Registration—of Examination on the part of those who enter business after said date;—of having been in business before said date by others.

"Annual Register to be published and be evidence.

"Penalty on wilful falsification of Register.

"Penalty on obtaining registration by false representations.

"Penalty on falsely pretending to be a registered person, or keeping open shop for dispensing said prescriptions, not being registered.

"Registered Chemists and Druggists, having passed Minor Examination, may be elected as, and continue and use title of, Associate of Pharmaceutical Society, and may vote at Meetings of the Society.

"Saving of rights of duly qualified Medical practitioners.

"Benevolent Fund may be applied to past Members and Associates, also to Parmaceutical Chemists and Registered Chemists and Druggists."

MR. GRIFFIN AND THE POOR-LAW BOARD.

Mr. Griffin, in anticipation of the Poor-law Medical Relief question being again brought under the notice of the House of Commons, has printed and published a Summary of the Principal Points of Evidence submitted to the Select Committee of the House of Commons on Poor Relief. In this summary, Mr. Griffin urgently presses upon the notice of the House of Commons the grievances at present suffered by the Poor-law Medical Officers, and the measures which ought to be introduced in their favour, and he also exposes the erroneous conclusions which Mr. Cane, one of the Inspectors of the Poor-law Board, has drawn upon the whole subject of Medical Relief to the Poor. We very much fear that the lawyers and other officials of the Board are the reverse of friendly to the Medical Profession, and we, therefore, advise our brethren throughout the country to be true to themselves, and to second Mr. Griffin in his persevering endeavours to obtain for them an adequate degree of justice at the hands of the Legislature. Mr. Griffin's pamphlet should be in the hands of every Poor-law Medical Officer.

MISS GARRETT AND THE MEDICAL CORPORATIONS.

From the pass-lists published in the newspapers, it appears that Miss Garrett, who is well known to be pursuing her Medical studies with a view to qualifying herself for practice, has passed a second ordeal at one of the Medical Examining Boards, the first being the Preliminary Examination in Classics and Mathematics, in which branches, we have been informed, she not only passed respectably, but most creditably. In her recent examination she has gained another step, having qualified herself, by her attainments in Anatomy, Physiology, Chemistry, Materia Medica, and Botany, to present herself hereafter for a final examination for a licence to practice. It is matter of public notoriety that many of the Examining Boards have refused to admit Miss Garrett to examination, but in the case of some of them, which are regulated by the provisions of certain Acts of Parliament, it appears that, as a mere matter of dry law, they have no power to exclude her, and are, therefore, without choice in the matter, and must admit her to examination if she presents the necessary documents and complies with the requisite formalities. Whatever may be thought of Miss Garrett's proceedings, as a precedent for the conduct of others of her sex, (and we ourselves have serious misgivings on the subject), it is quite impossible to deny the merit of great industry and energy, amounting to moral heroism, to this accomplished young lady. Impelled by no sordid motives, inasmuch as her resources are sufficient, and her social position most respectable, she has voluntarily devoted herself to pursuits, which, to the majority of her sex, are distasteful, and positively repulsive; while in the collateral studies relating to Medicine, she has proved herself not only equal, but in many instances superior, to her male competitors. Driven from one Medical institution, she has sought refuge in another; denied the means of acquiring information in the English Schools of Medicine, she migrated to those of Scotland, and, being there denied attendance at the public lectures, she availed herself of private instruction. Returning to England, she applies for permission to attend the dissecting-room of one of the Hospital Schools, and the permission is withheld; but, undaunted by the obstacle, she obtains, by night, the practical knowledge which she is unable to acquire in the day; and as she is refused the privilege of entering the Hospital as a student, she obtains an engagement as a nurse, and acquires for herself the knowledge which she vainly seeks from the assistance of others. As we have before remarked, we offer no opinion as to the propriety or expediency of committing the treatment of disease to women, but in the instance to which we refer, we cannot withhold our admiration for the courage displayed under circumstances which would have daunted the spirits of most men, and which, it might have been thought, would long ago have crushed the aspirations of a woman.

DR. MOORE AND THE POOR-LAW BOARD.

It is but too plain that the Medical Profession have little or nothing to expect from the tender mercies of the Poor-law Board. Dr. Moore having been dismissed by the Bethnal Green guardians, on grounds which are utterly untenable, the Poor-law Board has sanctioned the dismissal by requesting him to resign. The Poor-law Board does not pretend that any charges have been established against Dr. Moore, unless, indeed, it be that he has occasionally used black ink for red, or red for black, we forget which, in some of the entries in the parochial books. But the Board thinks that he ought to be called upon to resign, on grounds of expediency, as they do not think that he and the Guardians can act together in harmony. Not one word do they allow to escape them of the horrible condition of certain parts of Bethnal Green, the purification of which has been effected mainly by the energetic remonstrances of Dr. Moore, and the true condition of which the Bethnal Green Guardians long attempted to conceal. They lay great stress upon some strong expressions employed by Dr. Moore in reference to the Guardians, and which we do not intend to defend, except on the ground of enormous provocation: for when a man is boldly accused of lying, pilfering, and extortion, it is almost too much to expect that he will tamely submit to the imputations; and the very consciousness of his innocence will sometimes increase his indignation, and cause it to exceed the bounds of moderation. If the Poor-law Board imagine that they will gain popularity by thus attempting

to whitewash the Bethnal Green Guardians, they have made a grievous mistake, for public opinion, in this case at least, is in favour of the Medical victim, and the records of Poor-law cruelty and neglect in Bethnal Green will long cry out "trumpet-tongued" against the iniquities which may be sometimes perpetrated by local mismanagement.

REVIEW OF THE PERIODICALS.

The 'Lancet.'

Mr. Solly commences a series of "Clinical Lectures on Diseases of the Spine and Paralysis," and relates the particulars of two cases recently under treatment at St. Thomas's Hospital. One was that of a sailor, who was precipitated from the topmast during a gale of wind, and who sustained a serious injury to the spine, from which, however, he eventually recovered, under the use of caustic over the lower portion of the spine, mild and continued doses of mercury, and eventually quinine and strychnia. The other case was that of a man who had been a soldier, and whose spine had become injured by long marching, and exposure to wet and cold. He was treated successfully by the use of the moxa to the region of the spine, the internal employment of quinine, and wearing a spinal support.——Dr. Edward Smith contributes his second paper on "Dietary in Disease," and describes the treatment of spareness of habit, which is to be corrected by lessening any marked activity of the vital functions, and supplying starchy, oleaginous, and highly nitrogenised food, in as large a quantity as can be digested. Milk is one of the most useful articles of food for this purpose, as it contains fat and nitrogen in large quantities.——Mr. Hancock continues his "Cases Illustrative of the Benefit derivable from Division of the Ciliary Muscle." In one, this operation was successful after iridectomy had failed; in another, it was successfully substituted for the extirpation of the eye-ball; and in another, the division of the ciliary muscle of one eye was the means of restoring sight to the other.——Dr. Thomas Palmer offers some observations on "Subclavian Murmur," which, as Medical Officer to certain benefit societies, he has frequently heard in cases where the subjects were apparently in perfect health. He attributes the sound to pressure upon the subclavian artery by some accidental cause, and does not attach to it much pathological importance.——Mr. C. F. Pollard relates "A Case in which Extensive Fibrinous Coagula in the Heart and Large Vessels were Diagnosed previous to Death." The case is interesting at the present time, when the subject of coagulation in the vessels during life is exciting great attention.

The 'Medical Times and Gazette.'

Dr. Garrod continues his "Lectures on the British Pharmacopœia," the present lecture being principally devoted to a description of the changes in the preparations and compounds made in the new work. A list is given of the chief omissions and new introductions, none of which, however, are of very great importance, and many involve only technical or nominal alterations. But the liquid extract of ergot is described as a preparation worthy of notice, and useful in obstetric practice; the liquid extract of opium is intended as a substitute for the present sedative solution; and the liquid extract of pareira is said to possess all the valuable properties of the plant.——Mr. J. Z. Laurence commences a series of "Lectures on the Optical Defects of the Eye." The present part is devoted to some introductory observations on the laws of optics and the nature of light.——Dr. Julius Althaus communicates a very learned and elaborate paper on "Trichina Disease: its Prevention and Cure." The history of this parasitic worm has lately acquired fresh interest from the fact that its introduction into the human system through the medium of certain articles of food, especially pork, has been lately ascertained to cause disease and death. The trichinæ, as is well known, were first accidentally observed in the muscles of a body in the dissecting-room of Guy's Hospital, and were described by Professor Owen as belonging to the tribe of nematoid worms; and since that time their characters have been minutely examined by a multitude of observers, especially by Virchow and Leuckart. The worm itself, and the disease to which its presence gives rise, have been abundantly observed of late years, especially in Germany, and several fatal cases have been recorded. With regard to the propagation and development of the trichina, the curious discovery has been made, that just as the cysticercus cellulosæ is the larval state of the tænia solium, so the *encysted* trichinæ are the larval conditions of the *free* trichinæ. Thus, if a dog is fed with encysted trichinæ, numerous free trichinæ may be found a few days afterwards in the intestines of the animal. When trichinæ are introduced in the encysted form into the human stomach and intestines, they appear to burst from their covering, and assuming the free state, they force their way into the general structures of the body. While the cysticercus and the tænia seldom cause death, fatal results are often caused by the trichina.

REVIEW OF BOOKS.

Excision of the Scapula. By James Syme, F.R.S.E. Pp. 35. Edinburgh: Edmonston and Douglas. 1864.

This little work contains the details of three cases in which an entirely new operation was performed by Mr. Syme, and as the proceeding is a formidable and dangerous one, but nevertheless may become absolutely necessary in certain cases, the operator has done well in describing it. The first case was that of an old woman who presented a large tumour involving the left scapula, which was removed, though not without great danger from hæmorrhage. The patient recovered from the shock of the operation, but afterwards sunk, apparently from old age, and the tumour was found to be composed of a mixture of osseous and cerebriform matter. The second case was that of a man, aged forty-three, who presented a somewhat similar disease to that described in the last case, and in whom also the scapula was removed. The tumour, on microscopical examination, presented a suspicious appearance, but still the patient was well fifteen months after the operation, and an illustration is given in the frontispiece of the appearance the man presented after his recovery. In the third case, which was that of a gentleman aged forty, there was a growth of a fibro-cartilaginous character of the head of the

humerus, which was excised by Mr. Syme; but the disease returned, and the scapula was, therefore, removed, with a successful result. In relation to the formidable operation described in this monograph, Mr. Syme draws the conclusions, that "the entire scapula, either alone, or together with the arm, may be removed without much difficulty or loss of blood; that the wound thus inflicted may heal quickly and soundly; and that the arm, if preserved, may be strong and useful;" and he therefore trusts that Excision of the Scapula will be recognised as a legitimate and established procedure in Surgery.

On Paralysis, Neuralgia, and other Affections of the Nervous System; and their Successful Treatment by Galvanisation and Faradisation. By Julius Althaus, M.D., M.R.C.P.L., Physician to the Royal Infirmary for Diseases of the Chest. Third Edition. Pp. 236. London: Trübner and Co. 1864.

Since the discovery of electricity, a variety of attempts have been made to render its powers available in the treatment of disease, and it is, indeed, not to be wondered at that so powerful an agent should be supposed to be endowed with therapeutical properties. As soon as the electrical machine was invented, the sparks obtained by friction were applied in the treatment of paralysis and other diseases; and when, at a subsequent period, the phenomena of galvanism were exhibited, the continuous electrical current was called into operation on account of its supposed curative powers. Still more lately, our distinguished countryman, Faraday, ascertained that electric currents, of an interrupted character, might be obtained from a permanent steel-magnet, and these currents were also applied to the treatment of disease, especially by Duchenne, by whom this method of employing electro-magnetism has been called "Faradisation," and is known at present in France by that name. As usually happens in the case of the discovery of a new and powerful agent, its therapeutical properties are often over-estimated, and its application is often misunderstood, and such has certainly been the case with electricity and its modifications, galvanism and electro-magnetism, which have often been employed therapeutically by electricians unacquainted with medicine, and sometimes by Medical men unacquainted with the principles of electrical science. Dr. Althaus has the double merit of thoroughly understanding electricity in all its forms and applications, as well as being an able and accomplished physician, and in consequence, his book has become a trusthworthy guide upon the subject of which it treats. The present is the third edition, and it has been carefully revised, and enlarged by numerous scientific and practical additions.

GENERAL CORRESPONDENCE.

THE USE OF MERCURY.

To the Editor of the Medical Circular.

SIR,—Permit me, in the briefest possible terms, to answer a letter addressed to you by Dr. Drysdale, and published in the MEDICAL CIRCULAR of Feb. 17th.

In my communication, to which the letter of your correspondent is a rejoinder, I mentioned the name of Dr. Gooch in connection with mercurial administration, merely because he, being a man of the very highest distinction and of acknowledged merit, must be looked upon in Medical subjects at least, as an authority, and more particularly as an authority upon the *good* to be derived from the proper administration of the drug, which Dr. Drysdale I fear unwisely, has proposed *to blot out altogether* from the list of therapeutic agents.

I employ the word "unwisely," for I think that the great mercurial opponent, by carrying his antipathy to the drug too far, and urging against it such an array of objections, without allowing it even one good quality, has damaged, or at least tended to damage, the cause he might otherwise have so ably advocated and supported.

It was right to quote the opinion of Dr. Gooch, since he has shown, in his report upon cases of "irritable uterus," the immense benefit accruing to the sufferers from the administration of the medicine now under consideration.

I might have advanced a number of names in support of the *fact* that mercury *is* a most powerful *remedial* agent, and the names so advanced would have been of men esteemed and renowned in the Profession for their acute observation, and for those other qualities which form sound and discriminating practitioners. But I rest satisfied with the names I have already brought forward, and will not even now fall back upon the body of reserve which I have at command.

Dr. Drysdale, at his leisure, might peruse the essay of Dr. Gooch.

In reply to the question, "For what end is the drug to be given in typhoid fever?" I will refer the inquirer to the article upon typhoid fever, written by Dr. Wood in his "Practice of Medicine," since in it he will find the answer, and which, based upon the experience of Dr. Wood himself, must command attention.

I would ask Dr. Drysdale if he has never heard of mercury being prescribed in the morbus coxæ of even scrofulous subjects, and prescribed with most decidedly beneficial effects? Surely he has both heard of it and seen it.

I have now before me a case, which in the course of last summer I saw in Dublin, under the care of Dr. Walshe, of that city. It is that of a little child, who was dying of tabes mesenterica, and with whom the usual remedies were used, but without effect; hydrarg. cum cretâ was administered, and very soon the condition of the patient became improved, and he subsequently left the hospital with the disease not only arrested, but wholly "got under," so that he was again able to enjoy life, the disease having been *mastered by the poisonous* (?) *drug*, and made rapidly to yield place to renewed health and strength.

I cannot understand what Dr. Drysdale means by—"With regard to irritable uterus, it has been my lot to see mercury frequently given in inflammation of the cervix uteri, &c., but *never with any good* effect." In the first place, I would say irritable uterus has nothing whatever to do with the subsequently mentioned affection—namely, inflammation of the cervix; and, secondly, Dr. Drysdale does not state to *what form of inflammation* reference is made in his words; moreover, from his quotation of Dr. Hewitt's opinion, I am inclined to think he imagines "inflammation of the cervix uteri, &c." to occur only in the "puerperal states." Again, I must mention that I do not *remember* Dr. Hewitt to have said "Mercury was of no service in *any* puerperal states." I should like Dr. D. to define what he means by "puerperal states." Is the bichloride of mercury wholly inert in thickened and indurated conditions of the cervix uteri? In allusion to another part of Dr. D.'s letter, I would make answer, that I hope, upon a future occasion, to bring forward examples of rupia, ecthyma, pemphigus, in which the subjects of the affections had not been submitted to the influence of either mercury or syphilis.

I give again—again, because it has been published before—the following history of the case to which Dr. D. has alluded, inasmuch as that contained in his letter differs materially from what I have previously stated, and from the report I am bound to make of the patient's condition at the time Dr. D. took his notes.

The patient asserts "that the sore felt quite hard,—that there was very little, scarcely any matter from it—that he had a bubo in the left groin about a week after the sore appeared—that this bubo was opened, and that a good deal of matter came away—that when this bubo was healing, and about a month after its first appearance, another came in the right groin—that it also was opened, and gave exit to much matter—that each bubo took about a month to heal—that he never had any enlargement of the glands, *till* the sore appeared, and that then, *for the first time*, he noticed enlarged and hardened glands in the neck—that the sore was on the left side of the urethral orifice on the glans." Concerning his present condition, I have to state that he is covered *all over* with spots and cicatrices—that there are large indurated glands in both groins—both

axillæ and in the neck—that on his admission he had no red line at the margin of the gums, nor any sponginess of them, indicative of having had mercury administered—that mercury, no matter how given, always disagreed with him, and aggravated all the appearances of the malady, while, under simple treatment, he made a comparatively rapid and steady progress to health.

Dr. Drysdale says:—"At present he has the marks of a *mild* attack of rupia on his face and various parts of his body." Why, sir, he was covered with the marks of a *most severe* attack of the disease in question, and the "marks," *comparatively* light upon his face, were, at the time, in a condition—passing as they were through their several stages—characteristic of the severe form which the malady had assumed. Had Dr. D. seen the patient some weeks previous to the occasion of his taking notes, he could never have used the words "mild attack."

I know not how Dr. D. can surmise "that probably the patient took a three months' course of bichloride of mercury, in small doses, at Haslar, and more at Holloway;" because the gums were at no time made even tender, nor has the system ever in any way been affected by the treatment either at Haslar or at Holloway; moreover, there was *no sign* of mercurialisation when the patient presented himself at the Lock, and whenever he took mercury during his stay in the last-named hospital, he was invariably made worse, whereas, by the treatment pursued at the first two mentioned places, he was benefited, and, apparently, cured, as he was likewise by the *simple* course of treatment which was tried with him at the Lock Hospital.

Again, supposing—which of course I do not admit—that the patient *had* taken the bichloride, Dr. Drysdale's statements cannot be made to hold good—since they are conflicting—because he thus writes, in the words of Dr. Bennett,—"This disease I have *never* met with but in individuals who have been subjected to mercurial *poisoning*." Now, sir, I contend that Dr. Drysdale cannot adduce one sign upon which to rest his supposition, that the patient was, at one time or another, subjected to "mercurial poisoning"—not one link in the entire history of the patient could be pointed at as indicating any "mercurial poisoning." Dr. Drysdale says,

"The sore was a *soft* one."

I published in one of your previous numbers the fact that the sore was a *hard* one, as the man himself told me at the time, and still persists in saying.

By the Doctor's asking:—"How do we know that the rupia was not entirely caused by the mercury?"—I opine he considers the syphilitic taint in no wise connected with the causation of the skin affection. I will grant him this—since I deem it a truth, and one at which he has arrived—that mercury, if it has produced deterioration of the health, will, or may, *per se*, tend to rupial disease, or will actually produce it.

Dr. Drysdale writes, "there is no enlargement or induration of the glands:" this I am in justice bound to oppose, since it does not accord with the result of my examination made both before and after Dr. Drysdale had seen and examined the man. The glandular conditions I have mentioned above.

I must ask, how can we diagnose the cicatrix of a soft sore from that of a hard one?

I beg to state that I *have* brought forward as full an account of Mr. Erichsen's case, alluded to by Dr. Drysdale, as was necessary, and that it is published in your hospital reports for this year, and that I understood from Dr. Drysdale that he was going, immediately after his visit to the Lock, to the University College Hospital, for the express purpose of giving the patient himself a thorough cross-examination.

Furthermore, in one part of his letter your correspondent states:—"Rupia is met with but in individuals who have been subjected to mercurial poisoning;" while in another he has it, "Syphilitic bone disease has been seen only in those cases which have been submitted to a *course* of mercury."

With many apologies for encroaching upon your space, already replete with communications upon this subject,

I am, &c.,

G. de Gorrequer Griffith.

Claverton Terrace, St. George's Square.

P. S. I would draw attention to the fact, that we Allopaths have been vigorously attacked in 'The Monthly Homœopathic Review," and that one of the subjects which forms the ground of attack is, "The Use of Mercury in Syphilis."

POOR-LAW MEDICAL REFORM ASSOCIATION.

To the Editor of the Medical Circular.

Sir,—Be good enough to allow me space to inform the Poor-law Medical Officers, that on March 30, I forwarded to the Select Committee on Poor Relief a pamphlet containing a Summary of the Principal Points of Evidence relating to the Medical Relief of the Poor, which I had the honour of submitting to them last February. I did so in consequence of observing in Knight's 'Official Advertiser,' that "it is understood the Committee have determined not to examine any further witnesses, and are now considering their report." Having, therefore, great fear that my evidence might not be taken into consideration, I adopted the simple course of sending a condensed report of it to each member of the Select Committee, thinking it just possible that during the Easter Recess he might have leisure to read it.

Mr. Cane, in his "statement" to the Committee, took my evidence, and replied to it almost *seriatim*. I have adopted a similar course with his statement, and in like manner have given a rejoinder, which I hope will entirely refute his plausible but erroneous conclusions. I regret that the low state of the finances would not permit me to print a sufficient number of copies for all the Poor-law Medical Officers; one, however, I have sent to each of the subscribers to the Association for this year, and so far as the remaining part of the 200 copies will go, I shall be glad to forward them to those who may send their subscriptions. I understand that it is probable the Committee will shortly make their report to Parliament. I sincerely trust it may be favourable to our views, but whether it is so or not, I feel convinced we have proved our case, and judgment ought to be given in our favour.

Since March 20th, I have received the following subscriptions:—

R. T. Morris, Wigan, 1*l.*; P. A. L'Fargue, Meriden, 5s.; W. Prowse, G. Farthorne, B. A. Brickwell, all of Amersham, 2s. each; Dr. Barker, Aldershot, 5s.; T. Odell, Atfield, 10s.; H. J. Dowling, 5s.; T. M. Kendall, Freebridge, Lynn, 10s.; T. Harper, J. N. Stevens, J. H. Hicks, W. Dale, J. H. S. May, all of Plymouth, 2s. 6d. each; A. S. Kingdon, Bideford, 10s.; T. L. Pridham, Bideford, 5s.; A. Fernie, Barnstaple, 10s.; J. P. Berryman, St. Anstell, 6s.; W. B. Irwing, Newark, 5s.; G. Hardy, Rugby, 5s.; Dr. Smith, Weymouth, 1*l.* 1s.; G. T. Smeathman, Wycombe, 5s; H. S. Wood, Tavistock, 5.; W. B. Young, Reading, 10s; T. L. Walford, Reading, 5s.; F. Workman, Reading, 5s.; H. Dodgson, Cockermouth, 5s.; H. Bell, Cockermouth, 5s.; H. Giles, Witham, 1*l.*; E Moore, Bethnal Green, 2s. 6d.

I am, &c.

12 Royal Terrace, Weymouth, April 2, 1864. Richard Griffin.

New Voltaic Pile.—M. Maistre Fils has proposed a new voltaic pile. The peculiarity consists in the employment of iron instead of zinc for the oxidable metal, and in the arrangement of the charcoal or copper discs; these, which are circular, are all placed on a spindle which can be made to revolve; the discs dip into the liquid in the cups to such an extent that about one-third of their surface is covered; the exciting liquid employed is water containing a hundredth part of its volume of nitric acid. Iron is considered better than zinc, because there is no danger of its forming a deposit on the discs, the revolution of which prevents their becoming coated with hydrogen, and so rendered inactive.

BRITON MEDICAL AND GENERAL LIFE ASSOCIATION.

The tenth annual general meeting of shareholders and members of this Association was held at the head office on Thursday, the 17th of March. Francis Webb, Esq. (Deputy-Chairman), presided, in the absence of Dr. G. H. Barlow (the Chairman of the Board), who was professionally attending an important trial in the provinces. The Association will be more familiarly known to the Medical Profession as the New Equitable Life Assurance Company, which is now incorporated with the Briton under the present title. The New Equitable was founded by the late Mr. Wakley for the purpose of securing to the members of the Medical Profession a proper remuneration for the important services rendered by them to life assurance companies, and which, up to the date of its formation, had received no adequate recognition.

It is stated that the Briton Medical and General (and New Equitable) Life Association has in the past ten years paid in medical fees over 17,000*l.*, and that during the last two years alone the fees paid amount to 4,844*l.*

The Chairman said, among other observations, that one-fourth of the proposals brought before the Board had not been completed, showing that the same care and vigilance which had always characterised this Office, and which had been the greatest causes of its success, had still been exercised. Notwithstanding the rejection of so many proposals, they continued on the ascending scale as regarded the new premiums. They had gone from 10,000*l.* and 15,000*l.*, to 18,000*l.*, and next year they hoped to do 20,000*l.* or 21,000*l.*, and this showed that they were looked upon throughout the country as one of those offices which agents had pleasure in recommending. This continuous rate of progress was very satisfactory. The receipts for the past year were 113,000*l.*, and after deducting all expenses and claims of which they had any knowledge, up to the 31st of December, there was a surplus of 45,000*l.*, to carry over to the reserve fund. Any office that could carry over one-third of its income was doing exceedingly well. It was one of the data by which they could judge of the soundness of an office. One-third of the income of this Association would be 37,000*l.*, whereas they carried over 45,000*l.*, notwithstanding many extra expenses.

The state of the Association was considered by the meeting to be highly satisfactory, and the proceedings terminated by the usual votes of thanks to the officers.

DEATHS.

AMESBURY.—On the 27th ult., suddenly, J. Amesbury, M.R.C.S.E., of Lansdowne place, Brighton, aged 68.

ANDERSON.—On the 16th ult., at Nice, Dr. Anderson, of Newburgh.

BELL.—On the 26th ult., at Jedburgh, J. Bell, M.D., aged 34.

BEVERIDGE.—On the 15th ult., at Tarbert, J. H. Beveridge, L.R.C.S.Ed.

CHEETHAM.—On the 24th ult., at Eaton road, Chester, J. K. Cheetham, M.D., of Rochdale.

HALL.—On the 24th ult., at White House, Longton, John Marshall Hall, youngest son of Robert Hulme Hayes, L.R.C.P.Ed., aged 3 years and 3 months.

HUNT.—On the 19th ult., at Bournemouth, Hants, J. J. Hunt, L.K.Q.C.P.I., of Danesfort, Mallow.

INCE.—On the 25th ult., Eugene S. Ince, M.D., of Wilton street, Grosvenor place, aged 28.

JOHNSTON.—On the 18th of Feb., of typhus fever, at Antrim road, Belfast, Francis Graydon Johnston, M.R.C.S.E., formerly of St. Angelo, Co. Fermanagh, and late of Charlton, Kent.

MAITLAND.—On the 28th ult., at Blackburn, Richard Maitland, M.D., and J.P. for the County of Lancaster, aged 69.

M'GILCHRIST.—On the 27th ult., at Castle street, Edinburgh, John M'Gilchrist, M.D.

SANDERSON.—On the 15th of February, at Kurrachee, Dr. J. T. Sanderson, 1st Bombay Light Cavalry.

THOMSON.—On the 14th ult., at Edinburgh, J. Thomson, Student of Medicine, of Fochabers, Moraysbire, aged 20.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 24th ult.:—Evan Evans, Llandyssil, South Wales; Francis Fox, Ringwood, Hants; John Hall, East Retford, Notts; Albert Lloyd, Bristol; Revett Powles, Coleridge, Ipswich; James Ricketts, Liverpool; Edward Thomas Shaw, Packington street, Islington.

On the 23rd ult.:—Alfred Philipps, Lamb's Conduit place, W.C.

The following gentleman passed his first examination on the 24th ult.:—Frederick Edward Worthington, Manchester.

ROYAL COLLEGE OF SURGEONS.—Professor Huxley brought his course of twenty-four lectures on the Structure and Classification of the Mammalia to a close on Saturday week. Professor Fergusson will not commence his course until June next, when he will deliver six lectures on the Progress of Surgery during the present century.

DESTRUCTION OF THE DUBLIN APOTHECARIES' HALL BY FIRE.—On Wednesday last a fire broke out in the stores of the Apothecaries' Hall of Dublin. It was one of the most destructive fires that have occurred for a long time—property to a considerable amount (it is reported 15,000*l.*) having been sacrificed. This is not surprising when it is considered that the stores were filled with pharmaceutical preparations. It was first observed a little before 5 o'clock a.m., and was completely extinguished at 7; but in the interval the building was completely gutted. The books and valuable laboratory machinery were saved.

PRIZE ESSAY ON TOBACCO.—Among the prize questions of the Belgian Academy of Medicine is one for the best essay "to exhibit by observations and experiment the effect of the use and abuse of tobacco in a healthy man," for which a medal worth 300 francs will be given.

ARSENICAL POISONING BY ABSORPTION.—On Saturday, February 27th, Mr. B. L. Gross, one of the coroners for Suffolk, concluded an enquiry into the death of a child named Boatman, the daughter of a small farmer at Wissett, near Halesworth. The deceased was aged nine years, and lived with her father and stepmother. The child was taken ill, gradually got worse, and died soon after a Medical man was called in. The surgeon (Mr. Howard), feeling satisfied that the child died from poison, refused to certify the cause of death. An inquest was accordingly held, and when the jury viewed the body the scalp of the head was found to be in a shocking state from ringworm, and covered with vermin. The stepmother stated that about ten days before the death of the child she applied some precipitate powder and a little poison in the shape of an ointment to the head, to kill the vermin. The coroner ordered a *post-mortem* examination, and the appearance of the intestines and stomach pointing to arsenical poison in some form or other, it was felt important to ascertain whether the child died from arsenical poison, and if so, how it was administered. The viscera were accordingly sent to Professor Taylor, who stated at the inquest that the child died from arsenic applied externally, and absorbed into the system. The condition of the viscera, in their appearances, in the nature of their contents, and in the minute imponderable quantity of arsenic present in them, was not consistent with the supposition that arsenic had been given in a solid form or in a liquid form by the mouth, but it was quite consistent with the absorption of the poison through the skin of the scalp, and its subsequent diffusion by the blood. The scalp of the deceased was found to contain a large quantity of arsenic associated with a quantity of mercury (white precipitate), which had been applied as above stated in the form of an ointment. The jury returned a verdict to the effect that the deceased died from the effects of an ointment containing arsenic applied to her head by Mrs. Boatman, she being ignorant of the consequences, and intending merely to heal disease of the scalp; at the same time the jury desired the coroner to express to Boatman and his wife their sense of the neglect and ill-treatment of the deceased.

Professor Owen, F.R.S.—This distinguished physiologist had the honour of delivering a lecture on Natural History before the Queen and Royal Family on the 29th ult., and will deliver three more by command of Her Majesty.

Imports of Medicines from China.—From a return just published, it appears that during the year 1862, there were imported into this kingdom from China :—Camphor, 1,222 cwt. ; cassia lignea, 345,140 lbs. ; oil of cassia, 20,166 lbs.; other essential oils, 62,634 lbs. ; rhubarb, 165,326 lbs.

The Health of Portsmouth.—In consequence of a paragraph which appeared in the 'Morning Herald' and 'Standard,' of the 25th ult., relative to the smallpox at Portsmouth, the Mayor thought it advisable to convene a meeting of the medical gentlemen who are practising in the borough, to confer on the subject, and to take such steps thereon as might be deemed expedient. More than two-thirds of their number attended the meeting, and the following resolution was adopted :—"That the cases of smallpox which have occurred in the borough of Portsmouth have been of a modified type of the disease, and the few deaths which have resulted, in this large population, have taken place principally among those persons who have not been vaccinated, and in densely crowded or ill-ventilated localities."

Western Circuit: Bristol, March 29th.—(Before Mr. Baron Martin): Long v. Marsh.—The plaintiff was a surgeon at Thornbury, in the county of Gloucester, and the defendant was a tin merchant there. The plaintiff, having been in difficulties, had been compelled to go through the Court of Bankruptcy, and the defendant, as one of the debtors, was summoned to the Court and admitted the debt, but resisted payment on the ground that the plaintiff was not a proper practitioner. The plaintiff then produced a receipt from the Council of Medical Education for fees for registering him. The defendant stated upon his oath that the receipt was a forgery. The Court of Bankruptcy then refused to make an order on the defendant for payment, but an action must be brought which would enable the plaintiff to prove his qualification. The action was then brought. The judge said that the document referred to by the plaintiff was a receipt from the Medical Council, while the declaration alleged it to be a certificate from the College of Surgeons. Leave was ultimately given to amend the declaration before the first day of term, or the plaintiff would be nonsuited.

Royal Medical College, Epsom.—Sir Charles Locock, Bart., M.D., has consented to preside at the annual festival of this excellent institution. We trust there will be a numerous gathering of our brethren to support the worthy baronet, and to testify by their presence and subscriptions the interest they take in the College.

The Royal Infant.—On the 17th ult., the infant child of their Royal Highnesses the Prince and Princess of Wales was vaccinated. The vaccine produced the desired effect, and the Royal infant has passed through the various stages of the process in the most satisfactory manner.

Presentation to a Military Surgeon.—A meeting of the 16th Kent Royal Volunteers was held last Monday week for the purpose of presenting a sword to Dr. Penfold, the honorary surgeon of the regiment. The chairman, W. Walter, Esq., on behalf of the subscribers and friends, warmly eulogised the exertions of Surgeon Penfold, to which he responded in suitable and feeling terms.

The late Dr. Tobin, R.N.—On the 17th of February, Dr. John Kelly Tobin died at Brussels, aged seventy-nine. He commenced his career in the Royal Navy, was present at the capture of the fleet in the Basque-roads, afterwards entered the army, and was present during the Peninsular War in seventeen general actions, and retired on half-pay of the 9th Lancers, in consequence of wounds.

Sanitary Regulations for the Transport of Troops.—Deputy Inspector-General of Hospitals C. A. Gordon, C.B., has published some remarks on sea transport for troops for India and China. He strongly advises the establishment of a regular organized line of transports under naval agents, commanded by the senior officers of the station, each ship to be commissioned for three or five years, and attached to victualling yards in India and China ; the erection of a grand island sanitarium, a transport department in Egypt, a receiving vessel at Alexandria, as at Hong Kong, and other improvements on the present system which deserve the serious attention of the authorities, who must be desirous of mitigating the grave evils which at present exist, as Dr. Gordon points out.

Foreign Co-operation with the Registrar-General.—The Registrar-General has recently brought under the notice of the authorities of the great cities of Europe a plan for securing returns of diseases and of the weather simultaneous with those of London. Vienna, which is the seat of one of the greatest medical schools of Europe, has already responded to his application, and he expects to receive from that city a regular series of returns which cannot fail to afford interesting comparisons with those of London. Vienna is about to adopt many of the sanitary improvements which have worked so beneficially in England; and Dr. Glatter, a most zealous officer of the City Council, has undertaken the task of measuring their effects on the prevailing disease and the rate of mortality.

Pathology and Treatment of Aphthæ.—In the 'Gazette Hebdomadaire,' Dr. Jules Worms treats, in a recent paper, of a disease which is lost in the host of buccal affections described by modern authors. His subject is *aphthæ*, a denomination formerly applied to every superficial and acute irritation of the mucous lining of the mouth, and which Guersant, Billaut, and Gardien have shown to consist in a vesicular and ulcerous eruption of the mucous membrane, which runs its course in the period of one or two weeks. From minute examination of the deposit on the surface of aphthæ, Dr. Worms concludes that it consists of a fatty matter, which is not to be found in any other disease of the mouth, and exclusively characterises aphthæ. The epithelium rises and soon breaks, exposing to view a yellowish secretion, previously discernible through the transparent cuticle, and of which the microscope and the chemical tests invariably show the sebaceous nature. It may, on the other hand, be remarked that aphthæ are never met with on the anterior portions of the mucous membrane, where anatomists have failed in discovering any municiparous glands, and where *herpes labialis* more commonly occurs ; hence Billard's surmise that aphthæ are a disease of the mucous follicles, characterised by a peculiar sebaceous deposit, acquires additional probability. In Mr. Worm's opinion, aphthæ are, therefore, but the *acne* of mucous membranes. This practitioner infers from the solubility of the exudation in ether that this substance may be a useful local remedy for aphthæ. The pain caused by the eruption, and the difficulty of checking its progress, are well-known features of the disease, and the inefficacy of cauterisation, chlorate of potash, anodynes, and other methods of treatment usually prescribed, is very generally acknowledged. Mr. Worms has, on the contrary, resorted to ether with much benefit; this remedial agent removes the yellowish secretion, a new epithelium promptly forms, and no trace of the superficial ulcers remains beyond slightly increased vascularity of the mucous membrane. Ether may, therefore, be applied locally with advantage, but the fact of the frequent connection of aphthæ with gastric disturbance must at the same time be borne in mind. —'Journal of Practical Medicine and Surgery.'

APPOINTMENTS FOR THE WEEK.

Wednesday, April 6.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m. ; University College Hospital, 2 p.m.; Royal College of Physicians of London, 5 p.m.—Dr. George Johnson, "On the Laryngoscope : The Method of Using the Instrument, and the History of its Invention ;" Hunterian Society, 8 p.m.—Dr. Risdon Bennett, "On a Case of Hydatid Disease of the Liver ; with Remarks ;" Obstetrical Society of London, 8 p.m.—Papers by Dr. Meadows, Dr. Day, Dr. Barnes, &c.

Thursday, April 7.—*Operations* at St. George's Hospital, 1 p.m. ; Central London Ophthalmic Hospital, 1 p.m. ; London Hospital, 1½ p.m. ; Great Northern Hospital, King's cross, 2 p.m. ; West London Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m. ; London Surgical Home for Diseases of Women, 2 p.m. ; Royal Institution, 3 p.m.—Prof. Helmholtz "On the Natural Law of the Conservation of Energy

Harveian Society, 8 p.m.—Mr. Weeden Cooke, "On the Tumours affecting the Female Breast," following a Discussion "On Diphtheria."

FRIDAY, APRIL 8.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Physicians of London, 5 p.m.—Dr. George Johnson, "On the Laryngoscope: Illustrations of its Value in the Diagnosis and Treatment of Disease;" Royal Institution, 8 p.m.—Dr. J. Percy, "On Iron."

SATURDAY, APRIL 9.—*Operations* at St. Thomas's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; Royal Free Hospital, 1½ p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements."

MONDAY, APRIL 11.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, APRIL 12.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

An Elementary Text-Book of the Microscope. By J. W. Griffith, M.D., F.L.S., &c. London: John Van Voorst.

The Prescribers' Companion. By Alfred Meadows, M.D., M.R.C.P. London: Henry Renshaw.

The Social Science Review. April, 1864.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

IGNOTUS.—The Bael is the fruit of the *Ægle marmelos*. It is very much used in India in diarrhœa and dysentery, and is there considered as a specific in those affections.

F.R.C.S.—Our meaning must have been wilfully misunderstood by some one who had not taken pains enough to read the article.

A COUNTRY SUBSCRIBER.—We cannot take any further notice of the subject alluded to, although the case has our fullest sympathy.

Dr. J. L. EARLE'S paper on Post-partum Hæmorrhage will be inserted next week.

Mr. GRIFFIN.—The subject shall be noticed.

X. Y.—The book is a very good one, and it has been favourably noticed in our columns.

A SUFFERER is most strongly cautioned to avoid the advertising quacks, and to take the opinion of his own Medical attendant, or of some respectable practitioner in his neighbourhood.

PATERFAMILIAS.—1. Latin is required at nearly all the preliminary examinations, but Greek, in some cases, is optional. 2. Oxford and Cambridge are very good schools of Medicine at present, and the only objection to them is the expense of maintenance of the pupils.

T. V.—Chloroform has been employed, and with advantage, in dysmenorrhœa.

REGULAR SUBSCRIBER.—Probably the case recorded by Mr. Embling, of the appearance of the menses in a child of two years of age is unique; we are not acquainted with any other instance in which this function was called into activity at so early a period. The following is a brief abstract of the case to which we have made allusion:—The child had begun to menstruate when she was only two years old, and when seen at the age of three years "the mammæ were as healthily developed as in an adult of twenty years; the nates were also developed, the pubes having a slight flush of hair upon them; the labia, &c., were found to be in that condition which exists in a matured young person; the hymen was perfect, and the vagina, at least anteriorly, was of large size; the countenance was antique, and altogether the babe of three years had the appearance and gait of a little old woman. Menstruation and its concomitant pains were regular.

MR. ALFRED FREEMAN.—The name does not appear in the Medical Register or the Medical Directory for the present year. We are, therefore, unable to answer the question.

THE copy of the 'Belfast News-Letter' has been received.

Royal Medical Benevolent College.—The Council have the pleasure to announce that SIR CHARLES LOCOCK, Bart., M.D., has kindly consented to take the chair at the TWELFTH ANNUAL FESTIVAL of the College, which will take place at Willis's Rooms, King Street, St James's, on Saturday the 14th of May next, when it is earnestly hoped that there will be a large meeting of the friends of the Institution.

Gentlemen who are willing to serve as stewards on the occasion are requested to forward their names to the Treasurer, John Propert Esq., 6, New Cavendish Street, W. There is no liability attached to the office.

By order of the Council.

37 Soho Square, London. ROBERT FREEMAN.
30th. March 1864. Secretary.

St. Bartholomew's Hospital and MEDICAL COLLEGE. SUMMER SESSION commencing May 2.1864.

LECTURES.

Materia Medica.—Dr. Farre
Botany.—Dr. Harris
Forensic Medicine.—Dr. Martin and Dr. Odling
Midwifery.—Dr. Greenhalgh
Comparative Anatomy.—Mr. Callender
Practical Chymistry.—Dr. Frankland and Dr. Odling.

The Hospital contains 650 beds, and Clinical Lectures are delivered on the Medical Cases by Dr. Burrows, Dr. Farre, and Dr. Black; on the Surgical Cases by Mr. Lawrence, Mr. Skey, and Mr. Paget, and on Diseases of Women by Dr. Greenhalgh.

COLLEGIATE ESTABLISHMENT.—Students can reside within the Hospital walls, subject to the collegiate regulations. Some of the teachers connected with the Hospital also receive students to reside with them.

Seven Scholarships, varying in value from 20*l.* to 50*l.* are rewarded annually. Further information respecting these and other details may be obtained from Mr. Holden, Mr. Callender, or any of the Medical or Surgical officers or Lecturers; or at the Anatomical Museum or Library.

Anatomy, Physiology, Pathology, and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.—

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Emperor Life and Fire Assurance SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

MAKERS TO THE QUEEN AND PRINCE OF WALES

FRY'S | HOMŒPATHIC ICELAND MOSS PEARL | **COCOA.**

FRY'S SOLUBLE CHOCOLATE.

FRY'S CHOCOLATE for Eating in sticks and drops.

The superior quality of J. S. FRY and SONS' Articles has been attested by uniform public approbation during a century.

They are the ONLY English house in the trade to whom a PRIZE MEDAL was awarded 1862.

Instruments made of the Laminaria DIGITATA, Uterine Tents, see 'Med. Times and Gazette.' Nov. 28th 1863, page 558, T. G. Wilson, on Uterine Tents. Couper's dilating Uretha Bougies and Styles for dilating the Lachrymal duct, as used in the Royal Ophthalmic Hospital, Moorfields, may be had of C. W. KROHNE, 241 Whitechapel Road, London.

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared in a GRANULAR and EFFERVESCENT Condition the Constituents of the following MINERAL SPRINGS:—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT, &c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER:—
GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS:—
GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.
GRANULATED AND EFFERVESCING CITRATE OF QUININE.
GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.

143, NEW BOND STREET, LONDON.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 212.)

The Preventative Treatment.

I wish I could express in words how deeply I am impressed with the importance of employing certain precautions or remedies in every case of midwifery, for the purpose of preventing the occurrence of post-partum hæmorrhage. If the assertion were to be made, that half the number of cases of flooding which occur after delivery could be prevented by ordinary care on the part of the Medical man or patient, I believe it would be rather below than above the mark. Before I put into force the various precautionary means presently to be described, I was constantly meeting with flooding, whereas now I rarely do. Two or three Medical men have told me that they very seldom attend a case without flooding coming on afterwards; one of these gentlemen practises in a most healthy rural district too. Others, on the contrary, state that in their practice it is quite the exception for flooding to occur. It is impossible to attribute such different results to mere chance or luck. The true explanation is to be found in the mode of attendance. Flooding will be most frequent in the practice of Medical men who trust too much to nature, or are, on the contrary, very meddlesome.

The precautions which we may employ in preventing flooding after delivery should have for their aim more or less the insuring of two points—*perfect rest of body*, and *perfect contraction of the uterus.*

Prec. I. — The patient ought to be confined in bed. Amongst the upper class it is the usual mode of delivery; but the poorer class will almost invariably be confined with all their dayclothes on, at the foot of the bed, with the mattress turned up. They raise the three following arguments for being confined in that manner. 1st. They consider the stays are a great support and assistance. The only feeling of support which can be derived from stays must be from mere habit, from constantly wearing them; and against their use we know that they impede respiration, which is already rendered difficult from the pressure of the diaphragm upwards by the displaced abdominal viscera. 2nd. They require some fixed point against which they can place their feet in order to bear down, and another fixed point to which they can attach a towel to pull at, and thus further assist nature's efforts. Extraordinary efforts, as may be effected by such means, are perfectly unnecessary, and in some instances actually injurious; many a ruptured perinæum has been produced by straining too violently during the last stage of labour. Any straining, if necessary, can be effected in bed by holding the hands of the nurse, shutting the mouth, and bearing down. 3rd. The danger of messing the sheets when confined in bed. This is the most forcible argument these patients possess; for if the bedclothes are not properly protected, they are liable to become soiled by liquor amnii and blood. The "making of the bed," as it is termed, should be superintended by the surgeon, especially when attending upon the poor, for the nurses in that class are so ignorant as not even to know how to manage this simple affair properly. Many of them place the oilcloth, etc., in the centre of the bed, which not only renders the manipulations of the accoucheur more awkward, but any extra amount of discharge runs over, and wets that part of the sheet which lies between the oilcloth and the edge of the bed. Whatever is placed on the bed for its protection ought to have a good portion hanging over the edge, and the patient to bring her buttocks as near to the edge as possible, in order that if there should happen to be any unusual amount of discharge it may run off.

The patient's dress may consist either of the ordinary night-clothes, or, as I prefer it, a clean chemise and night dress well drawn up round the waist, and the rest of the body covered by a flannel petticoat and a single old skirt, with the feet enveloped in thick woollen stockings. It is better to let the patient stand or sit until labour has far advanced, unless she is exhausted from loss of sleep or from the length of the first stage; but she should be dressed ready for some time before she lies down, especially if from the previous labours we learn that they are quick, or if we find the os dilating rapidly. The great advantage of being confined in bed and dressed in the manner stated is that it ensures perfect rest after the termination of labour. I have several times noticed, in women who had been confined at the foot of the bed, the uterus well contracted, and no hæmorrhage while they remained there; but after all their day-clothes had been removed and clean things put on, and they had been literally dragged into bed, that the uterus had become large and tender, and hæmorrhage had commenced which, in some instances, could not be arrested without introduction of the hand, and the removal of clots.

Prec. II.—A small tablecloth, or, if there are two binders, one of them should be adjusted before the termination of labour, in fact, as soon as the patient is undressed. It ought to be passed (the patient standing up) once round the abdomen outside the skirt, and made to reach a little above the fundus of the uterus and a little below the hips, and then pinned four or five times on the *right side* of the patient. It should not be drawn tight except in cases where the uterus is very much anteverted from great flaccidity of the abdominal walls, as it prevents the fundus from taking the natural forward movement during a contraction. I used to put on the binder after delivery, but to adjust it properly while in the recumbent posture requires a considerable amount of exertion on the part of the mother, as some difficulty is generally found in getting the lower edge well under the hips; and sometimes it gets twisted, then it has to be removed and re-applied. There are many advantages in adjusting the binder before delivery:—1. It ensures perfect rest of body. 2. It can be more easily and more equally applied. 3. By pinning the binder on the right side of the body as she lies on the left we are enabled to tighten or loosen it at pleasure.

Prec. III.—The nurse should be instructed to tell the patient to empty her bladder frequently. The more cases of midwifery I attend, the more I feel convinced that a distended bladder is not an uncommon cause of post-partum hæmorrhage. I shall enter more fully into the consideration of distension of the bladder when I come to treat upon the subject of the causes and their treatment.

Prec. IV.—When the patient lies down, care ought to be taken that the head and trunk are placed higher than the pelvis, especially so just before the birth of the child; otherwise hæmorrhage is liable to be set up by the blood gravitating to the upper part of the vagina, and there forming a clot, instead of passing away out of the vulva. The vaginal clot obstructs the escape of blood from the uterus and affords it time to coagulate in the cavity of that organ. Clots in the uterus is a most common cause of post-partum hæmorrhage.

Prec. V.—The character of the previous labours, and of the present one, should be carefully studied. For example, if we find out from enquiry that the patient is *a flooder*, that is to say, always has an excessive loss of blood after her confinement, a dose of ergot should be administered as soon as the child's head is born, and another as soon as the rest of the child is delivered; or if we notice during the present labour that the delivery of the child is being effected by pains which occur at long intervals, we may be pretty sure that the uterus will act as slug-

gishly after delivery, and that hæmorrhage will arise from inertia. Ergot should be given in the same way in these cases as in those in which flooding occurs after every confinement, as the cause in both is the same. I may mention here, that when I first commenced systematically to carry out precautionary means for the prevention of post-partum hæmorrhage, I tried the effect of ergot after the birth of the child's head in every case I attended, thinking by so doing I should ensure perfect contraction of the uterus; but I was not at all satisfied with the result, for in the first instance, it very often gave rise to fearful after-pains, and, secondly, it sometimes produced the very evil I wished to avoid, viz., an excessive loss of blood. Ergot is very useful in the cases above mentioned, for, as the cause in both is inertia, the ergot excites the normal contraction of the uterus, and no more; whereas, if we give it in ordinary cases, we have the normal uterine contraction, plus the effect of the ergot, giving rise to inordinate action of the uterus, which not only causes great suffering, but often an undue loss of blood.

Prec. VI.—When the infant's head is born, the nurse should be directed to place her right hand over the fundus of the uterus, and to follow the uterus down as she feels it descend during the expulsion of the infant. This assists in preventing the uterus being left in a flaccid condition.

Prec. VII.—The child ought to be allowed to be expelled by the efforts of nature, unless its life is in danger; the only artificial aid generally necessary, is to direct the head and shoulders forward. There is usually an interval before the uterus commences to contract again, whenever it parts with any considerable portion of its contents suddenly, as when the liquor amnii is discharged, or the head is expelled, and when the rest of the body is born. If we pull away the infant without waiting for a contraction, the uterus is liable to be left large and uncontracted; and should a portion of the placenta become detached, before the uterus takes upon itself to contract, hæmorrhage is an inevitable consequence.

ON CLOTS IN ARTERIES.

By Dr. G. de Gorrequer Griffith.

As this is a subject fraught with immense interest, not only to the obstetric practitioner, but likewise to the general physician, as well as the general surgeon, no apology is necessary for making some remarks upon a case lately under the care of Mr. T. Nunn, published in our number for February 10.

It is reported that on the "5th of July the patient is only semi-conscious," and that on the "9th the power over the right side is lost." The notes for the 10th go on to say "died at 8.45 p.m., sixty days after operation." The post-mortem examination revealed the heart to be not only "flaccid and fatty," but to have "vegetations on the mitral valves toward their bases."

Thinking it not improbable nor impossible for the semi-consciousness and the loss of power over the right side to be at least in a measure connected, it occurred to my mind that both these conditions might be due to part or some of the vegetations having been washed off the mitral valves, urged by the systolic action of the heart into the general circulation, and hurried along until it (the vegetation) came to occupy a vessel the calibre of which was not sufficiently capacious to allow of its transit; hence its arrestment at a particular point and the supervention of the symptoms above noted.

I do not mean to assert this surmise as a fact, but feeling interested in the subject of clots in arteries, and the consequences of such an accident, I would venture to ask the opinion of Mr. Nunn upon this view of his case, since were it in affirmation with my conjectures, the case might be cited as another instance of the sequences of clots, or vegetations, in arteries.

Bearing upon this subject, Dr. Simpson has collected a number of cases which induce him to think arteritis and arterial obstruction, as occurring after labour, not so infrequent as was supposed, and that the paucity of published and recognised cases arose from the non-recognition of the peculiar symptoms, and the difficulty in detecting the pathological results of the lesion.

He enumerates as the several causes of the obstruction:—First, the separation of cardiac vegetations; second, the passing forward into the current of the circulation of unorganised blood coagula, or of fibrinous masses from the cavity of the heart; third, local arteritis; fourth, diseases of the blood; fifth, laceration of the internal coats of the vessel. To this last, as a cause of obstruction, Professor Turner some years since drew attention, and Dr. Oke, of Southampton, has published a case considered to be illustrative of the Professor's observations; the following is an abstract of it:—Hæmorrhage occurred during pregnancy, abortion supervened; to this succeeded coldness and anæsthesia of the left arm, as well as discolouration of the tips of the fingers, and absence of the pulse at the wrist; the cardiac and respiratory functions were properly executed, there being no disease of the heart or lungs. The extremities of the digits dropped off as a consequence of the gangrene which attacked them; the sphacelus extended no farther, and the limb became restored to its wonted healthy aspect and conditions. The patient lived for some time after, and exhibited no cardiac lesion.

There is a case mentioned by Dr. Simpson, in the 'Medical Times and Gazette,' for 1854, and which had been furnished to him by Dr. Burrows; the woman was a puerperal subject, and to all appearance suffered from the consequences of over lactation; there were also present obscure rheumatic pains in the limbs; hemiplegia suddenly set in after using a little more exercise than usual; a systolic cardiac bruit was quite audible on examination; the memory and the speech became affected; death supervened. The necropsy showed mitral and aortic valvular disease, vegetations being situated on both sets of valves. The left corpus striatum, owing to the process of ramollisement, was reduced to a mere diffluent pulp, while the artery supplying it with blood had, at its very origin from the middle cerebral, became choked up with a small mass like a grain of wheat.

Dr. Burrows had correctly diagnosed the case during life—first, from the fact of the woman being a puerperal patient; secondly, the presence of the cardiac valve disease; thirdly, the sudden hemiplegia, loss of memory, and other symptoms of ramollisement.

In 1847, in the March number of the 'Monthly Medical Journal,' Dr. Simpson recorded this case:—Previous to impregnation, the lady had laboured under endocarditis, and during the time she carried the child there were repeated attacks of dyspnœa; hæmorrhage at eighth month, dependent for its production upon placental presentation. The child was born alive, the long forceps being used to effect delivery; convalescence went on for a few days, when a sudden accession of decidedly untoward symptoms presented, and in the second week the pulse had ceased to exist from below the elbow, and the entire limb was cold, stiff, and insensible. Pulsation in right forearm returned very gradually, but the vessels of the lower limbs seemed to have been occluded. Erratic phlebitis attacked the patient, and she succumbed apparently from phlegmasia dolens of the left arm and left side of the face. At the post-mortem, the left vena innominata was found entirely closed by a plug of lymph, and the humeral artery at the elbow was in the same condition. There was no evidence of laceration of the inner coats of the artery. The uterus was quite healthy. The valves of the left side of the heart were studded with vegetations, the washing off of which by the blood into its current had, in the opinion of Dr. Simpson, occasioned the occlusion of the artery and the consequent symptoms.

Another case is recorded by Dr. Simpson:—The patient was young; had a premature labour, the child being her first; continued to do well for three weeks, at the end of which period feverishness and diarrhœa supervened, and the lochia began to assume a sanguineous appearance; neu-

ralgic pains, sometimes of a very severe type, attacked the lower extremities, especially the right. Seven weeks subsequent to labour, a sudden pain was experienced in the left groin, and a loud bruit could be heard with the heart's systole. A few days after these symptoms had presented, the pulse ceased to beat in the right arm—the cessation was complete and sudden. On the day following, an arterial beat could be detected in either femoral artery; gangrene of the toes of the left foot supervened, and the patient died.

There had been no previous history of any rheumatic affection.

The post-mortem examination demonstrated the pelvic and abdominal organs to be for the most part sound and healthy; the spleen, however, was pulpy, and studded throughout with masses of lymph.

The valves of the aorta were encrusted with friable vegetations, while the vessel itself was occluded by a plug of lymph just about its bifurcation into the iliacs; these latter vessels were likewise choked up by the same lymphy material, which at several points encased some purulent matter, as well as small bodies resembling the vegetations, by which the valves were encrusted.

The humeral artery of the right side was, as well as the other vessels, occluded at its bifurcation, and the femoral vein of the left side was found to be inflamed.

The plugs by which the vessels were blocked up were not unlike the cardiac vegetations.

In Dr. Macfarlane's case, the vegetations on the valves were very small; there was no obliteration of the brachial and femoral vessels, and the upper part of the plug seemed to be one of, or a portion of, the valvular growths.

In a case of Dr. Lever, the arteries in both extremities of the left side ceased to pulsate, gangrene attacked the affected limbs, and death of the patient ensued.

The examination after death showed the arterial and venous vessels to be alike obstructed, and also that there were vegetations upon the valves of the left side of the heart.

This train of occurrences had followed an acute attack of rheumatism during pregnancy.

Dr. Kirke's cases had had developed symptoms, dependent upon occlusion or obstruction of the cerebral vessels, and at the necropsy, vegetations similar in appearance and structure to those studding the cardiac valves were discovered to be the offending cause.

In the cases brought forward by Dr. Simpson, the evidences in favour of the obstruction being the result of the transmission from the heart along the arterial channels of vegetations formed upon the valves of the heart, are these:—The patients had suffered from endocarditis; the arterial pulsations had been suddenly arrested, showing that the obstruction was instantaneous, and not gradual, as would take place were arteritis the occasion of the symptoms; at the autopsy, vegetations were found upon the valves of the heart, and bodies in every respect identical in appearance and structure with these valvular growths were found at the site of the obstructions. Again, it is not unusual for outgrowths in other situations to be thus cast off from the point at which they originate. Dr. John Reid has described the separation of polypus-like bodies from the pleural and peritoneal surfaces; and all are quite familiar with the separation which occurs in cases of polypi from various mucous surfaces, as well as with those instances in which foreign bodies in joints come to have an existence independent of the structure whence their primary development.

Cruvelhier relates a case, in which a needle had entered the left ventricle, had become the nucleus for fibrinous coagula, that, being detached from it, had been projected into the circulation, and had occasioned occlusion of the lower limbs. The result of this obstruction was gangrene.

"The fourth cause" says Professor Simpson, "of arterial obstruction, is certain diseased states of the blood, or morbid matters circulating in it. In puerperal phlebitis, there are particles of pus and fibrine circulating in the blood; at first passing from the uterine veins to the right side of the heart, and becoming deposited in the lungs, liver, &c. Now, pus or fibrine is known to serve as a nucleus for coagulating the blood, and in the pulmonary or other arteries, sometimes leads to the formation of obstructing masses. Two cases of puerperal obstruction of the pulmonary arteries from this cause are given by Cruveilhier; the possibility of various morbid appearances in the liver, spleen, &c., being attributable to the same cause is dwelt upon."

In conclusion, I would call attention to a specimen in the Pathological Museum of the New York Hospital; it is the heart of a boy, whose body had been submitted to an autopsical examination after death from wound of the subclavian artery, the septum cordis ventriculorum was found transfixed by a needle, and yet, during life, no serious symptoms had been manifested.

Claverton terrace, St. George's square,
April, 1864.

HOSPITAL REPORTS.

KING'S COLLEGE.

Operation by Mr. Henry Smith.

(Continued from page 229.)

Mr. Henry Smith then proceeded to operate upon a robust, strong, and active young man for the cure of fistula in ano.

The history is as follows:—Æt. twenty-five; four years ago, while serving in India with his regiment, he got an abscess of the rectum, which bursting, resulted in a fistula; for this latter he was operated upon, but without removal of the affection. Again, about a year subsequently, he had to undergo another operation, which likewise failed, as did also a third.

On a very close examination of the rectum, in order that the cause of this frequent failure might be ascertained, *a stricture of the intestine was found*, which at once explained the difficulty. The stricture in every instance prevents the fistula from uniting, and the operation fails, not from any want of dexterity and skill on the part of the operator, but merely because the exciting cause is allowed to remain. In this case, while the man had been under observation, and was being treated by Mr. Smith, the stricture was dilated and the wound healed; however, when the patient discontinued his visits to the hospital, he neglected to use the bougie, the stricture became as bad as at first, and the fistula returned.

At the present operation, the stricture was nicked on two sides, and the fistula was divided in the ordinary manner.

Mr. Smith particularly dwelt upon the inutility of merely dividing a fistula where it existed along with a stricture of the rectum, and laid down, as the proper course of treatment, the cure of the stricture, in order to effect that of the fistula. In this case, the fistula was on the left side, and there were the cicatrices of the former operations, as well as hypertrophied portions of integument, indicative of the sites of the fistulæ.

The second case upon which he operated was that of a man weakly and delicate, who had a blind external fistula. The common plan of treatment was put in requisition.

The object of the methods of treatment in stricture of the rectum, is obviously to remove that condition of the bowel. This may be effected either by simple dilatation, or by division of the part with the knife.

The first is effected by means of an instrument called the rectal bougie, and which differs from the urethral bougie only in size, being made of gum elastic. It should be used every second or third day, and thus, in many instances, it will succeed in removing the constriction. Sometimes, however, the affection is of so long standing, that the stricture has become very tight and very hard, in which case we may, and only with great difficulty, be able to pass a

small-sized instrument: we may also find it almost impossible to dilate the constricted canal, or to produce a decided impression upon the tightened and indurated tissues. Under these circumstances, it is advisable, in conjunction with the attempt to dilate by means of the bougie, to nick the tissues, and so to loosen the offending parts. The best knife for this purpose is a probe-pointed sheathed bistoury. This latter mode of treatment constitutes the operation by division.

After incising the tissues and freeing them, a sponge-tent, such as is used in the dilatation of the os and cervix uteri, must be passed (well oiled) into the intestine, and completely through the seat of stricture. It must be allowed to remain for twelve hours, and when withdrawn, should be replaced by a larger sized sponge-tent, or by a bougie, it being a mere matter of choice which will be used to produce a cure. The bowels must on no account be allowed to become constipated, and may easily be kept regularly and gently open, by mild aperients, or by enemata.

When the seat of stricture is very high up—not to be felt by the finger—even the procedure by simple dilatation is attended with much difficulty, and the difficulty is commensurate with the amount of tightness, as also with the degree of induration co-existent. If, however, we succeed in passing one instrument, how small soever it may be, there will be comparatively little difficulty of introduction experienced in using other instruments subsequently, because the first will act as a guide. The best position in which to place our patient is upon the left side. Too large-sized bougie must not be used, nor should any force be employed in the passing of it, lest we perforate the bowel, and induce fatal inflammation of the peritoneum. This is a danger less likely to occur when the stricture is situated low down than when it is high up, since, in the latter instance, not being able to make an exploration with the finger, we may be led into the error of imagining that we have entered the canal of the stricture, and acting on this supposition, we strive to overcome the resistance, in doing which we push the bougie right on through the walls of the intestine, the obstruction being occasioned not by the stricture at all, but by one of the valvular folds of mucous membrane lining the interior of the bowel below the constriction.

There is a great difference in the pain felt by patients; this will arise either from local sensibility, or from a condition of general irritability or nervous susceptibility, having for its origin the affection of the bowel, or existing antecedently. To relieve this pain, this hyperæsthesia, the ordinary opium suppository may be introduced; in a female, this may be passed into the vagina, so that there will be no occasion to withdraw the bougie.

There is so great a tendency on the part of the stricture to recur, that very frequently the simple dilatation will prove ineffectual, and we will at length be compelled to put into force the plan by incision.

When the stricture is high up, it in some cases has happened that the bougie, instead of entering it and passing through it, is caught by a fold of membrane, and is bent backward upon itself; all this time we may be led to suppose it is travelling upward through the intestine, when in reality it is returning to the anus.

If the obstruction be complete, it may be necessary to perform the operation for artificial anus, and according to the situation of the constriction must the opening be made. As, however, the disease more frequently implicates the bowel below the descending colon, the operation termed Amussat's is that generally required. Should any doubt exist as to the position of the stricture, it will be advisable to operate for the artificial anus in the right iliac region.

Before any such operative measures be taken, resort should first be made to oil and oatmeal enemata, with the hope that the bowels, excited to expulsive action, will overcome the obstruction and relieve themselves. While we are waiting for this result, the strength of our patient is to be supported by every kind of light nutritious food, and such as will not allow much residue to collect in the bowels.

Strictures are of two kinds, the simple non-malignant, or fibrous, and the malignant, or cancerous. The treatment to which we have just adverted bears reference only to the simple variety of the disease.

Fibrous stricture is usually met with in that part of the bowel where the rectum joins the sigmoid flexure of the colon. It is likewise very often found a little below this point—that is, about a finger's length from the anus; sometimes it exists higher up than the line of junction of the two portions of the large intestine—namely, in the descending, or even in the transverse, colon.

There is a form of simple stricture met at about an inch, or an inch and a half, above the anus; it occurs most frequently in those suffering from piles, when inflamed or acutely painful; from ulcer in the bowel; from acute fissure; from the effects of delection, or, as in not a few instances happens, from hysteria. In this kind of stricture there is no organic disease, the affection being merely of a spasmodic character, and generally involving the superficial sphincter; it is more common in young nervous females, and is sometimes dependent on a loaded condition of the bowels. The fibrous variety obtains far more frequently in those who are advanced in years, especially in elderly females.

The symptoms are difficulty in emptying the bowels, and straining in the effort to do so, which, coupled with some pain and tenesmus, at first slight, but increasing with the advance of the disease, as well as with habitual constipation, awaken the attention of the patient to the fact that something must be wrong. On examining the evacuations, they are found to be small, broken up into irregular-shaped pieces, hard, scybalous, and covered over with blood and mucous; diarrhœa will alternate with the constipation; dyspepsia and distension of the abdomen will harass the patient. The peculiarity of the diarrhœa is, that it affords very little, if any, relief, and that the discharges are almost altogether composed of the fluid excretions of the intestines, very little solid fæces being passed.

Complete obstruction can only occur when the organic changes have lasted for a very long time, and have steadily grown worse; it is, therefore, but a very slow process, and even when it does supervene, may last for some weeks before death results. Instances have, however, occurred, in which the obstruction came on quite suddenly, and all the symptoms of acute strangulation of the intestine followed, death quickly terminating the sufferings.

The abscesses which form in connection with stricture of the rectum burst into the vagina, into the rectum itself, the ischio-rectal space, or passing down to the nates, may form an opening in this direction, ultimately leading to what is ordinarily termed fistula in ano. The great tendency of these abscesses, wherever they burst, is to eventuate in fistulæ.

Very frequently the purulent discharge is most offensive in character. Hectic, rapid and extreme emaciation, mark the formation of matter, and the ulceration of the mucous membrane of that part of the bowel which is the seat of the constriction.

Peritonitis sometimes arises in consequence of a communication of the local irritation, or from the ulcerative process forming an opening into the sac of the peritoneum, or from the abscess emptying itself into the same sac.

Census of Occupations.—From the general classification of the population enumerated in England and Wales at the census of 1851, and that of 1861, it appears that the physicians increased from 1,771 to 2,385, but the surgeons and apothecaries decreased in number, the profession answering to the preference of the patient for the higher title.

The Army Medical Library at Aldershot, founded by Dr. Gibson, the present Director-General, has recently received a very important addition in the contribution, by Dr. Fleming, of 139 volumes. The 'Aldershot and Sandhurst Military Gazette' has made some observations on the library, which are worthy of approbation.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF
H. LETHEBY, M.B., M.A., Ph.D., &c.,

Fellow of the Linnean, and the Chemical Societies, Medical Officer for the City of London, and Professor of Chemistry in the College of the London Hospital.

No. X.

Aconitia.—The preparation of aconitine, almost up to the time of the publication of the British Pharmacopœia, was considered an extremely difficult matter. In 1836 the London College gave a process for extracting it, which unfortunately did not answer, and therefore in the Pharmacopœia of 1851 all mention of the alkaloid was omitted. The British Pharmacopœia now supplies a process, the usefulness of which is guaranteed by the fact that it is the method employed by some of the largest makers of this alkaloid, Messrs. Hopkin and Williams, who liberally placed it at the disposal of the committee.

The process may be shortly described as follows:—Coarsely-powdered aconite root is boiled for a moment with alcohol, and then macerated for a few days. The whole is then percolated, and the mass exhausted with spirit. The greater part of the alcohol is now recovered by distillation, and the residue is then evaporated over a water bath to drive off all the alcohol. This is an important part of the process, since if the whole of the alcohol is not removed, the aconitia will not be completely precipitated. The residual extract is afterwards mixed with twice its weight of *boiling* distilled water, and the mixture, when cold, is filtered. The object of this filtration is to remove a small quantity of green oil which separates from the extract on the addition of the water. A slight excess of ammonia is now added to the filtered solution, and a gentle heat is applied. In this way a mixed precipitate of aconitia, napellina, and some resinoid matter is obtained, which is collected and dried. It is then powdered, and digested repeatedly with ether. The etherial solutions are then mixed, and carefully distilled to dryness. The dry extract is treated with warm distilled water, acidulated with sulphuric acid, and the solution, when cold, is again precipitated by the cautious addition of diluted ammonia. The aconitine so precipitated is washed with a small quantity of *cold* water, and then dried by slight pressure between folds of blotting paper.

The aconitine so obtained is usually of a pale brown colour. It can be obtained quite white, by redissolving it in dilute sulphuric acid, and treating the solution with animal charcoal, but the loss is considerable, a matter of importance with so expensive a substance. It has been procured in crystals by Mr. Morson, who discovered the curious fact, that in the crystalline state aconitine loses much of its activity. We are not aware that any analysis of these crystals has been made, which if done might throw some light on this alteration of strength.

Aconitine is freely soluble in alcohol and ether, and dissolves in 150 parts of cold, and 50 parts of boiling water; the solutions are strongly alkaline to reddened litmus. It combines with acids, forming neutral salts, which have not yet been crystallised. These salts are readily soluble in alcohol and water; the solutions give a precipitate with sulphocyanide of potassium, bichloride of mercury, and terchloride of gold, but not with bichloride of platinum. Caustic alkalies precipitate the aconitine.

Concentrated sulphuric acid first colours aconitine yellow, and then violet; nitric acid gives a colourless solution. It is, of course, completely destroyed by heat.

The formula of Aconitia is said to be $C_{60}\ H_{47}\ O_{14}\ N$, but this formula must be accepted with some reserve, since it is doubtful whether the pure alkaloid has ever been analysed.

The practitioner who wishes to make sure of the effects of aconitine, should be careful to order the English, made by Morson and Son, or Hopkin and Williams, the only London makers. A good deal of the alkaloid of foreign manufacture is imported, and sold at a much cheaper rate, but it may be said to be worthless for remedial purposes. We have administered as much as four grains of an imported specimen to a dog without producing any apparent discomfort to the animal; while one-twentieth of a grain of genuine aconitia is sufficient to cause death.

What foreign aconitia is composed of is unknown. M. Barreswill supposes* that much that is sold is asparagine, or, in some cases, for the most part sulphate of lime. Asparagine would be difficult to identify; but sulphate of lime would be detected on applying the Pharmacopœia tests, since it would be left as a white residue on burning the aconitine, and would not be dissolved by ether.

We have mentioned another alkaloid found in aconite root. When the precipitate obtained by the addition of ammonia to the aqueous solution in the first part of the Pharmacopœia process is treated with ether, a considerable portion is left undissolved. This residue dissolves in alcohol, and also in dilute acids, from which latter solution it is again precipitated on the addition of an alkali. The exact nature of the precipitate has not yet been made out; but by appropriate treatment of the alcoholic solution, a white substance of a bitter and afterwards burning taste, and which possesses alkaline properties, has been separated, to which the name *Napellina* has been given. It is said to be distinguished from aconitia by not being precipitated by ammonia from a hydrochloric solution, and by being more soluble in alcohol and water. We know of no analysis of this substance, at all events under the above name.

Recently, Messrs. J. and H. Smith have described† an alkaloid which they have discovered in aconite root, and to which they have given the name of *Aconella*. It is extremely probable that it is the same body to which the name Napellina had been previously given. The Messrs. Smith assume that this substance has the same composition as Narcotina,

* 'Répertoire de Chimie Appliquée,' 1863, pp. 353.

† 'Pharmaceutical Journal.' Jan. 1864, pp. 317.

with which body they believe it to be identical. Aconella is said to be inert; the physiological properties of Napellina have not, so far as we know, been examined.

With respect to its therapeutical properties, aconitia possesses, in a concentrated degree, the characters of aconite, and is used in medicine chiefly as an external application in some cases of rheumatism and neuralgia. Its dose for internal administration is about the $\frac{1}{60}$ of a grain. The poisonous dose may be stated as about the $\frac{1}{10}$ of a grain.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. ERNEST HART commences the number with a Clinical Lecture on "Cataract, with reference to Improved Methods of Diagnosis and Treatment." Mr. Hart selects three cases in illustration of the different forms which cataract may assume, and of the different prognosis which ought to be formed in each case. In one instance, the nature of the disease was evident at once; in the other two, the morbid changes occurring in the textures of the eye were revealed by the ophthalmoscope, which instrument Mr. Hart declares to be not merely useful, but, inasmuch as its indications are infallible when cautiously sought for, inestimable According as the changes in the structures are more or less advanced, as revealed by the instrument, and according as the other textures besides the lens are affected, will the chances of success be favourable or otherwise under operative proceedings. In some cases erroneously supposed to be cataractous, the use of the ophthalmoscope will reveal the real nature of the disease, which may be unconnected with the lens.——Mr. REDFERN DAVIES, of Birmingham, offers some "Remarks on the Operative and Mechanical Treatment of Prolapsus Uteri," illustrated by a case. He agrees generally, in his mode of proceeding, with Mr. Baker Brown, but differs from him in some respects, as in using silver wires instead of twine sutures. Mr. Davies does not agree with Mr. Brown in entirely condemning the use of pessaries, as he considers that "Zwanke's pessary" is free from inconvenience.——Mr. WILLIAM COLLES contributes a paper on a "New Method of Using Arsenious Acid in the Treatment of Leprosy," and he illustrates his remarks by the details of three cases which occurred in India, in all of which the disease assumed a very aggravated form, resembling elephantiasis. They were treated externally by an ointment composed of arsenious acid and simple cerate, but an ointment containing the biniodide of mercury was also used. The treatment was very successful in all the cases.

THE 'MEDICAL TIMES AND GAZETTE.'

The number commences with a Lecture on the "Conservation of Energy," delivered recently at the Royal Institution by Professor HELMHOLTZ. This discourse seems quite out of place in a Medical journal, as the subjects of which it treats have hardly any bearing upon medicine. For this reason, and from the fact that it really contains nothing new, we make no analysis of it, although we have read it with pleasure as an exposition of certain facts and laws in Natural Philosophy and Astronomy.——Dr. GARROD concludes his Lectures on the "British Pharmacopœia," making some observations on matters of comparatively minor importance, as the composition of the liniments, spirits, tinctures, juices, lozenges, &c. With respect to the therapeutical employment of potash and soda, which are used indifferently by many practitioners, Dr. Garrod thinks it probable that each may possess distinct remedial properties.——Dr. JULIUS ALTHAUS concludes his very interesting paper on "The Trichina Disease: its Prevention and Cure." The diagnosis of this affection in the living subject was not made until 1860, when Dr. Zencker recognised an epidemic of the disease in the town and neighbourhood of Dresden, and showed the presence of the trichinæ in a ham and several kinds of pork sausages, of which the affected persons had eaten. Several became seriously ill, and one died, and on the autopsy of the latter, an immense number of trichinæ were discovered in the muscles of the body. The parasites were administered to several rabbits, and they all died, and in all the animals trichinæ were found in the muscles. Trichiniasis is considered by Dr. Althaus as being probably always caused by eating raw or underdone pork, hams, or sausages; beef, mutton, poultry, and game, never contain them. Dr. Althaus thinks that Moses forbad the use of pork to the Jews because it contained trichinæ; and he affirms that trichiniasis would never have occurred in the human species if pork had been eschewed. The objection to pork, however, only applies to the raw or imperfectly cooked article, as the heat employed in thoroughly cooking it, kills the parasites.

THE 'BRITISH MEDICAL JOURNAL.'

Dr. W. O. MARKHAM contributes his Gulstonian Lecture on the "Uses of Blood-letting in Disease," lately delivered at the Royal College of Physicians. After remarking that the views of the Profession have undergone a radical change, almost amounting to a revolution, on the subject of the efficacy of venesection, Dr. Markham proceeds to examine the theory of the change of type of disease, which has been put forward by some high authorities to account for the difference between the views entertained by the present and the past generation of practitioners. Dr. Markham is a strong opponent of the theory alluded to, and he maintains that disease has undergone no change of type at all, but that the present race of Medical men are more sagacious than their predecessors, who made very little inquiry as to the principles of pathology, but followed a system of mere routine in their treatment. Dr. Markham ridicules, and not without cause, the extravagant blood-lettings which were recommended and practised at the commencement of the present century, and his censures on the *indiscriminate* use of blood-letting by our ancestors, and even by some who yet remain among us, are not undeserved. When he tells us that large bleedings were adopted by some practitioners to ward off pulmonary consumption, or to cure diabetes (!) it may well be conceded that such practice

was irrational. But Dr. Markham is not so successful in proving that the nature of diseases has undergone no change during the present century. There is no more inherent improbability in the supposition that diseases have undergone a change, than that the range of atmospheric temperature during the last ten or twenty years has varied extensively, which we know to be a fact. Nor is it incredible that pneumonia or pleurisy may assume different types of a sthenic or asthenic character, any more than that some epidemics of scarlet fever may be malignant and others mild. We might as well deny that sweating sickness and plague once raged in London at periodical intervals, or assert, on the other hand, that epidemic cholera and epidemic influenza, prevailed in the time of Charles II, as they certainly did in the reign of William IV. To deny that occult influences may exist in the atmosphere at intervals and predispose to particular types of disease, would be to disbelieve not only the written evidence of the most distinguished physicians, from Hippocrates downwards, but to doubt the evidence of our own senses ; and indeed the only reason for our disbelief would be that we do not understand the reason of the phenomena.

GENERAL CORRESPONDENCE.

TESTIMONIAL TO MR. GRIFFIN.

To the Editor of the Medical Circular.

Sir,—Will you be good enough to find room in your journal, to inform the Poor-law Medical Officers throughout the country, that a subscription has been set on foot by me for a testimonial to Mr. Griffin, for his long continued and unwearied exertions in our behalf. It is now nine years that he has laboured with unremitting attention to our cause. Every one of us must admit that he deserves our highest commendation, and is worthy of a gratitude that should show itself in a substantial manner. We must open our purses as well as our hearts, and present him with some fitting acknowledgment for all the trouble he has taken, and the work he has so willingly performed on our account. This is our plain duty as true and honest men ; a duty that we owe not less to ourselves than to him, and we shall be much to blame if we neglect to obey the voice of conscience in this matter, and prove ourselves neglectful of an obligation so imperative. The editor of the 'Lancet' has kindly consented to receive subscriptions towards this fund, and I trust, Sir, that you will not object to do the same ; but will give the necessary publicity, and aid in your own remarks, for the accomplishment of so good a purpose.

I am, &c., Wm. Prowse,
Surgeon to the Union House and District.

Amersham, Bucks, April 7, 1864.

N.B.—Subscriptions to the Poor-law Medical Reform, Association should also be forwarded as early as possible, to Mr. Griffin, at Weymouth.

THE EXCISION OF THE SCAPULA.

To the Editor of the Medical Circular.

Sir,—My attention was drawn to the notice, in your last issue, of Professor Syme's interesting and concisely written book on Excision of the Scapula, and I was somewhat surprised to find that no allusion was made to the cases where this rare and formidable operation had been adopted by other British Surgeons. My astonishment, however, was great when I turned to the work itself, and found that Mr. Syme was completely silent with regard to the same point. As your reviewer says, Mr. Syme draws the conclusions that the entire scapula, either alone or together with the arm, may be removed without much difficulty or loss of blood ; that this wound thus inflicted may heal quickly and soundly ; and that the arm, if preserved, may be strong and useful.

I do not find fault with these conclusions, which are undoubtedly correct ; but I am astonished to find that Mr. Syme forgets, or pretends to forget, that excision of the entire scapula, had been shown to be a feasible operation several years before his book was written, and it is in justice to two cherished personal friends, one happily now among us, the other gone before, that I beg both the reviewer of the book and Mr. Syme to bear in mind that Mr. Fergusson removed the entire scapula with success in the year 1847, in a case where the arm had previously been taken away, and that Mr. Jones, of Jersey, performed the same operation in May 1858, on a young woman, at the same time preserving the arm, which in December of the same year was carefully examined by many surgeons in London, and found to be strong and useful.

Thus, in London, at least many years before the date of Mr. Syme's operation, Mr. Fergusson had fully shown that excision of the scapula might be performed both with safety and success, and I maintain that my lamented friend, Mr. Jones, has a prior claim to Mr. Syme, of having shown that after excision of the scapula, a strong and useful arm might be preserved, for his patient happily lived long enough to show this, whereas in Mr. Syme's first case the subject of the operation survived only two months, and thus it was impossible that, in that short period of time, any satisfactory evidence as to the usefulness of the preserved limb could be obtained, and Mr. Syme's second case was not operated on until November, 1860.

Surely, Sir, Mr. Syme must be well acquainted with the history of these two brilliant cases, and why then does he not deign even to allude to them ? A man in Mr. Syme's position, both as a teacher and writer, should show a better example of liberality, to say nothing of common fairness towards others equally zealous with himself in advancing Surgery. I feel sure that the writer of the notice, and your readers in general, will feel obliged to me for doing a simple act of justice towards two distinguished surgeons.

I am, &c., Henry Smith.

Caroline street, Bedford square.

A Manual of Diet and Regimen for Physician and Patient. By Horace Dobell, M.D., Physician to the Royal Infirmary for Diseases of the Chest. Pp. 36. 1864. Churchill and Sons.

Dr. Dobell states that his manual has been constructed to supply a want felt by most Medical men engaged in practice. It consists of a few plain and judicious rules in relation to ventilation and heating, clothing, sleep, exercise, posture, bathing, regulation of the bowels, rest and change, meals, and the essentials of a normal diet, and it then presents a series of diet tables containing lists of various articles of food, suited to different cases, and to be selected by the Medical attendant. The quantity of each article which may be consumed by one person in twenty-four hours is described, together with the relative amount of water, plastic matter, fat, saccharine and carbonaceous elements contained in each ; and the directions given are that in each instance, where the use of the tables is required, the articles described are to be allowed to the patient or not, according to the circumstances. This little book may prove useful for the purposes indicated.

Births and Deaths in London.—The last quarter of 1863 was remarkable for the small number of births and deaths in the city of London. That of births was the smallest on record, for it reached only 668, the average for the corresponding quarter of the last ten years being 807. The deaths also were below the average in the proportion 699 to 749. The number of deaths, too, in the quarter, had been greater than the births, an occurrence scarcely known except in the cholera year 1854, when there were 939 deaths to 789 births.

THE MEDICAL CIRCULAR.

WEDNESDAY, APRIL 13, 1864.

THE MEDICAL JOURNALS,—LEGITIMATE AND SPURIOUS.

There are few literary relations more agreeable than those which exist between the editors of Medical periodicals and their readers. There is an exchange of obligations honestly reciprocal, and whatever the pleasures we give, and whatever the services we render, the first fruits are our own. With the freemasonry of a brotherly feeling of kindness and equality between us, there are no secrets, no mysteries, to deny us the fullest frankness and cordiality of mutual communication. If we instruct to live, and live to instruct, we have the compensation attributed to those messengers of peace and good tidings whose feet are beautiful on the mountains, and we have added to all the other rewards of our labours, a share of whatever benefits arise from them through those thousand missionaries of usefulness whose practical alchemy is daily turning them into so many elixirs of health, and boons of life to the millions.

The world of Medical science revolves round the editor's chair, and his readers have the rare privilege of being made acquainted weekly with every new phenomenon in the physical action of man, that exhibits itself on its surface. Could we sum up, in a single exercise of the memory, all the increase of knowledge that is thus made in the course of every few years, we should ourselves probably be the first to be astounded at the improvement, and did we direct our attention to the results in active practice, our first feeling would be, that no eye, but the divine one, can appreciate all the mitigation that has thus come in to lighten the ills of the sick and dying, in the most unhappy of all the campaigns which humanity has to contest with misfortune. The farmer is proud of his plough, the currier of his leather, the mason of his mallet, the statuary of his chisel, the painter of his pencil or brush; but the agriculturist should not exclaim with more enthusiasm "speed the plough," than the Medical man, "speed the Medical journal."

It is no small pride either for the craft to be able to add that, whatever the development of Medical Science, we can assert that that of Medical journalism has not been behind it. The start which began with the rivalries set on foot by the 'Medical Gazette,' has been worthily followed ever since, and it may now be admitted that, in no department of literature, have readers a higher class of information placed at their command on more moderate conditions. Whatever the recommendation gathered from the variety, the extent, or the value of the materials supplied, is supported by that won from the spirit in which they are offered. There is, as a rule, a healthy tone in the comments, which redeem them alike from the Pecksniffism of semi-respectable censors and from the excessive zeal of an over-sensitive professional feeling. If nothing affecting our *esprit de corps* or our professional interests escape the notice of the Medical journalist, he may plead at all events that his vindication of the rights of his brethren does not carry him to any foolish pretensions against those of the public, and that in discussing the little matters which grow up within our boundaries, a spirit of mutual toleration and the amenities of gentlemanly relations are not lost sight of. There is not only plenty of useful work done for the profession under easy conditions, but the claim may be added that, as a rule, it has been well done, and done, as the general success shows, to everybody's satisfaction.

It would not be fair to ourselves not to own that, in our opinion, there is one dark shade to be introduced into the picture we have thus been sketching of contemporary Medical journalism. We cannot but think it is a mistake to have some thousand or two of our Medical friends uniting to be proprietors, publishers, and editors of a Medical journal, all for themselves. We fail to see, we will not say any necessity, but any plea for so large a portion of our English brethren engaging in such a speculation. There was everything they required in the journals already under publication on pecuniary terms to which no reasonable man could object; and whether they wished to be known as contributors to Medical science, or sought to make known new views on Medical politics or professional ethics, there was no lack of channels open to them to give them the certainty of communicating with the whole Medical body. Far from there being any likelihood of having themselves or their proceedings overlooked by the periodicals which are in communication with the Profession all over the world, there would be actually a rivalry among the journalists as to which should best fulfil the requisition. An association with public objects in view could never have such hope for an active advocacy and support as by relying on the voluntary concurrence of journals competing with one another for the preference of their members. We can understand an occasional publication giving an official record of the transactions of an association, and the suggestion was not an extraordinary one, which trusted that a journal on that basis would be a pleasant mode of using the surplus funds, and of giving remunerative employment to an increased staff. But it was not therefore a wise suggestion, nor in very good feeling. The Medical journals had done their duty by the Profession, and were entitled not to have the sphere of their usefulness cut down, or their rewards curtailed by an interference with that commercial success which was at once the proof and acknowledgment of the services they had been rendering. It is to be added, too, that an excess of competition is as bad as the opposite defect, since it is in the liberality of the support afforded by the Profession that must depend after all the power of the developing all the resources of their journals. In a profession like ours, there is but a limited *clientelle*, and to circumscribe it by a speculation which aims at the introduction of journalism independently of any question of supply and demand, and under all the disabilities and fetters of the co-operative system, is to take away those elastic elements of health and strength on which a really efficacious press depends. It is a mistake on one side, an injury on the other, and a review of all that the independent Medical journals have been doing, and have done, for the Profession

during the last twenty years, might have fairly suggested that those whose mercantile ability had been imperilled in the service, demanded, in the day of our common triumph, a different kind of acknowledgement.

These remarks have been called forth by a perusal of the last financial statement of the British Medical Association, from which it appears that nearly the whole of the funds of the Association are swallowed up by the expenses of their Journal, and that the balance is again on the wrong side! Out of 2,985*l.*, which is the total expenditure of the Association during the year 1863, no less than 2,716*l.* 10s. 10d.! has been expended on the Journal, leaving only 268*l.* for all the other expenses of the Association. Truly this is like Falstaff's pennyworth of bread to an intolerable quantity of sack.

We only ask, while three Journals already exist for the discussion of Medical intelligence, *cui bono* this enormous expenditure? The good sense of the Profession would readily point to far more advisable methods of spending so large an income.

SUMMARY OF THE WEEK.

GARIBALDI AND MR. FERGUSSON.

It has been stated in several of the newspapers that Dr. Fergusson, the eminent Surgeon, meaning of course Mr. Fergusson, of King's College, has tendered his gratuitous services to the illustrious patriot Garibaldi, who is known to be still suffering from the effects of the wound he received in the foot in the engagement at Aspromonte. The writers in the newspapers in question appear to think that this species of touting for practice, or at least for notoriety, is creditable, and, indeed, praiseworthy in a member of our Profession, but in the opinion of all honourable practitioners it is just the reverse. The truth is that Mr. Fergusson has done nothing of the kind, and has never offered his services to Garibaldi either gratuitously or otherwise. More than six months since, an application was made to Mr. Fergusson to visit Garibaldi at Caprera, but as the symptoms under which the General was labouring were relieved, the negotiations were broken off. It is believed, however, that Mr. Fergusson will be requested to visit Garibaldi on the arrival of the latter in London, but we know that he will not offer his services until they are required. The lameness under which Garibaldi is suffering is supposed to be due to some portions of necrosed bone in the seat of the original wound.

MR. GLADSTONE'S BUDGET.

We wish that we were enabled, on the part of the Medical Profession, to echo the general sentiments of approval expressed in regard to the Budget of the Chancellor of the Exchequer. But after the most careful examination, we cannot find that Medical practitioners will be benefited by the contemplated changes, except in a very infinitesimal degree. It is of very little consequence to us that the village shop-keeper is henceforth to pay half-a-crown instead of half-a-guinea for a licence to sell tea, or that a hawker is to pay the same rate for two horses as for one horse, or that stamps on proxy papers for railway meetings are to be reduced from sixpence to a penny. To us it is not of much more importance that fire-insurances on stock in trade are to be reduced one-half, and even the reduction of the sugar duties is not apparently very beneficial, as it is doubtful whether, among the sugar-growers, and the sugar-refiners, and the grocers, the reduction will ever reach the general public. As to the income-tax, and its proposed reduction by one penny in the pound, the change will no doubt be acceptable to many, but will be almost inappreciable by our professional brethren, who have already too much reason to complain that their precarious income is taxed in exactly the same manner as the income derivable from property. The mode of imposing the tax in the case of our Profession is also peculiarly galling, and often most unjust; for the assessors estimate a Medical man's income just as it pleases them, and the proof of over-charge is left upon the tax-payer, who is compelled, in order to obtain redress, to exhibit his private accounts to persons probably living in his own neighbourhood, and to whom such revelations cannot be made without a very natural repugnance on his own part; so that many are compelled to submit to extortion from the fear of exposing their poverty, or it may be, the dishonesty of their patients, to the scrutiny of the assessors.

THE UNCLEAN ANIMAL.

The recent investigations upon the new disease, which has been termed *Trichiniasis*, and which is shown to be caused by eating pork, are sufficient to inspire the pork-butchers with dismay, and to make the lovers of pork literally quake for their lives. When we call the disease a new one, however, we are probably in error, for a recent authority declares that it existed in the time of Moses, and that it was on this account that the Jewish legislator forbid the use of pork to his fellow-countrymen. The disease is caused by a minute parasitic worm, which infests the muscles of the pig, and which, being introduced into the human stomach and intestines, forces its way into the other structures, and at length propagates itself to such an extent as to enter the muscles of the body, and to induce a serious and often fatal disease, somewhat resembling typhoid fever in its character and symptoms. Pork alone, of all human food, contains the trichinæ; for the other animals in which these parasites are found, as the cat, the mole, the crow, the hawk, and the jackdaw, are, as is well known, never eaten, except, indeed, at some *cabarets* in Paris, where cats are sometimes served up as food. It is comforting, however, to know that the objection to pork, ham, or sausages, which may contain the trichinæ, does not apply to the well-cooked, but to the raw or imperfectly cooked article, for the heat employed in curing or cooking destroys the life of the worm. We may state, in all seriousness, that the Medical Department of the Privy Council are fully aware of the importance of this subject, and are taking it into their careful consideration, as it is believed that the

cause of many mysterious deaths may probably be found in the indiscriminate and improper use of the article to which we allude.

THE TESTIMONIAL TO DR. DAY, LATE OF ST. ANDREW'S.

The subscriptions to the proposed testimonial to Dr. Day having been collected, and the form of the testimonial having been determined upon, it is proposed that its presentation should be celebrated by a dinner of the graduates of St. Andrew's, on the 2nd of May next, at the London Tavern, Bishopsgate street, when Dr. Richardson will preside. It is thought that, independently of the presentation, the occasion will afford the opportunity for the graduates to renew many old acquaintanceships, and to maintain the social and friendly feeling which it is so desirable to maintain among the members of our Profession. A large number of graduates have already signified their intention to be present, and the meeting will no doubt be a very pleasant one. The gentlemen who have undertaken the duty of secretaries to the dinner committee are Dr. Dobell, 41 Harley street, and Dr. Paul, of Camberwell House, Camberwell, to whom applications for tickets should be made.

DEFEAT OF AN ATTEMPT TO INTRODUCE HOMŒOPATHY INTO THE BELFAST INFIRMARY.

At a late meeting of the Belfast Board of Guardians, one of the members read an application from a homœopathic practitioner, benevolently offering to attend the sick poor in the infirmary gratuitously, on homœopathic principles, and promising a great saving of human life from the change. The application was accompanied by the usual absurd pretensions and allegations made by homœopathic practitioners; but it also contained a most erroneous statement with regard to the mortality in the Belfast Infirmary, under the present efficient Medical superintendence. A reply was thus called forth from Dr. Seaton Reid, the Medical Officer, who, in a short and conclusive statement, showed the fallacy and inaccuracy of the charges made against the management of the institution. The application of the homœopathist was almost unanimously refused, only one member of the board voting in its favour.

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MR. E. CANTON, PRESIDENT.

CLINICAL DISCUSSION.

Dr. HABERSHON exhibited a specimen of

DISEASE OF THE HEART

affecting the mitral valve, which was rigidly contracted. The patient was a man aged forty-five, admitted into Guy's Hospital in September, with scarcely any symptoms. His health had been fair for three years. There was much dyspnœa, with dulness at the right base of the heart and pleuritic effusion. In two months he left the hospital, relieved. The heart was carefully examined, and the sounds were slight. From exposure to cold he got bad again. He was re-admitted under Dr. Barlow with similar symptoms, and had acute pleurisy of the opposite side, of which he died. The heart showed more than sufficient to cause prolongation of the first sound; the mitral valve would scarcely admit the tip of the finger.

Dr. HABERSHON related the particulars of a case of

ABSCESS OF THE LIVER

in a man at Guy's, aged twenty-two, who had been a steward on board a ship on the west coast of Africa. His health was good, with no fever, dysentery, or jaundice. Whilst at home at tea he was suddenly seized with pain in the right shoulder and severe pain in the right side. He had been ill six months when seen, and stated that he had an abscess of the liver. Careful examination showed evidence of the pleurisy of the right side when the abscess was making its way through the diaphragm; there was great tenderness over the liver, and he always rested on the left side; had no rigors. He died in two months. The liver was found to contain from twelve to twenty abscesses of various sizes; peritonitis existed between the liver and diaphragm, and the abscesses communicated with the pleura. There was no disease of the bowels, and no jaundice.

DR. ALTHAUS inquired if Dr. Habershon had ever known of an abscess of the liver bursting into the trachea, a case of which he narrated.

Dr. HABERSHON had known of such cases.

Dr. PLAYFAIR had met with such cases in India, and some of them had recovered.

Dr. THOMPSON thought it difficult sometimes to diagnose between abscess of the liver and empyema.

Dr. PALFREY and Dr. ROGERS referred to cases of hepatic abscess they had seen.

Dr. PALFREY related a case of

UTERINE POLYPUS UNACCOMPANIED BY HÆMORRHAGE,

in a woman, aged forty-eight, who had lost no blood for two years; she had severe leucorrhœa. On examination a polypus was found springing from the os uteri with a short pedicle. On the 9th of October last it was removed by Mr. Kilburn, with no pain or bleeding, and she recovered well. Now and then, he said, we meet with cases with symptoms of polypus for two or more years with no bleeding; and he thought we might fairly deduce that hæmorrhage is not necessarily a symptom of polypus.

Dr. ROGERS remarked that if the patient had not menstruated for two years it would be a reason for there being no hæmorrhage, and the growth was an indurated one.

Dr. GIBB exhibited

THE LARYNX OF A NEGRO, AND POINTED OUT THE DIFFERENCES BEWTEEN IT AND THAT OF THE WHITE MAN.

These consisted in the great size of the cartilages of Wrisberg, which were either absent or quite rudimentary in the white man, and of large size in the quadrumana. The vocal cords, in place of being flat and horizontal as in the white man, were more or less oblique from within outwards, their free border being elevated at a higher angle than their attached border, thus giving them a slanting or shelving direction outwards. The ventricles in the negro larynx take a direction outwards and downwards, so that any small body, such as a bead, placed upon the slanting vocal cord, would roll into the ventricle. In the white man the ventricle is situated external to, but immediately above, the plane of the true vocal cords. There were some other minute points of difference, but the foregoing were the three chief peculiarities which caused the larynx of the negro to more closely approximate the same organ in the quadrumana than it did the larynx of the white man.

The PRESIDENT remarked that these were important points added to others, as the feet, woolly hair, muscles, &c., all set forth by Dr. Hunt at the Anthropological Society. There did not seem to be as much attention paid to the internal organs. Mr. Nunn had found a peculiarity in the origin of the vessels from the arch of the aorta in the negro such as exists in the monkey tribe. It occasionally occurs in the white man, but in the negro it was more common and striking. He had seen the cartilages of Wrisberg sometimes largely developed in the white man.

Mr. WILLIAM MILLER described

TWO PECULIAR PROPERTIES OF CHLOROFORM INDEPENDENT OF ANÆSTHESIA.

The external application of chloroform produces a benumbing sensation. He had neuralgic pain of the throat on one

occasion, and a liniment of chloroform rubbed in produced no effect, but on soaking a piece of linen in the liniment and applying it, a burning sensation and redness were produced, as if a mustard poultice had been applied. He had used it the last four years in preference to a mustard poultice; it was cleaner, and ten minutes were sufficient to produce the desired effect. The liniment consisted of one drachm of tincture of opium, two drachms of chloroform, and two ounces of soap liniment.

The liniment was tried on the hands of several of the Fellows, and in two minutes violent burning heat and redness were produced.

Dr. Kidd observed that we were quite familiar with the blistering effects of chloroform, and he generally smeared oil on the face before using it.

Mr. Henry Smith related a case of

DOUBLE HERNIA OF THE SAME SIDE OF THE BODY,

one of which was strangulated, in a man of seventy-three. He had had an inguinal hernia of the right side for seventeen years, as large as a child's head, and as symptoms of strangulation occurred, he examined the patient, and found a small femoral hernia of the same side, which he reduced. The man recovered, but died afterwards from diarrhœa and bronchitis.

Dr. Morell Mackenzie brought forward a case of

WARTY GROWTH IN THE LARYNX OF A CHILD.

aged two years and four months. It caught cold at three months old, and since then had never been able to produce a vocal sound. It could neither speak nor cry. The laryngoscope could not be used, but with the finger a growth could be felt projecting from the receding angle of the thyroid cartilage, of almost bony consistence, probably enchondromatous. The child always appeared benefited by examination, yet he looked upon the case as one of considerable danger, and thought it a question whether it would not be desirable to perform tracheotomy.

Dr. Gibb mentioned that about eighteen months ago a child was brought to him with stridulous breathing since birth. On examining the larynx with his finger he felt a number of warty growths, but he could not use the laryngoscope. He intended to remove them with his finger nail, but lost sight of the child afterwards.

The President, Dr. Gibb, Dr. Rogers, and Mr. Mason examined the child, and were able with the finger to feel the tumour within the larynx.

Mr. Walter Coulson exhibited a

CALCULUS FROM THE BLADDER OF A WOMAN,

which he had removed through the urethra by means of a Weiss's dilator, without making any incision. She was forty-five years old, and the stone was the size of a large walnut. She recovered well without a bad symptom.

Mr. Bryant said that the urethra might be dilated to a large extent, if done rapidly under chloroform, without danger or bad result. This opinion was founded upon the examination of the statistics of a number of cases which he had collected together, and was opposed to that given in all the class-books. The largest per-centage of incontinence of urine arose from urethral lithotomy.

The 91st anniversary meeting of the Society was held at Willis's Rooms, King street, St. James's, on the 8th ultimo, E. Canton, Esq., in the chair. The following gentlemen were elected office-bearers for the ensuing year:—President: Dr. Greenhalgh. Vice-Presidents: Dr. Hare, Mr. Lawson, Dr. Davidson, and Mr. Harding. Treasurer: Mr. Rogers Harrison. Librarian: Dr. Palfrey Secretaries in Ordinary: Dr. Gibb, Dr. Symes Thompson. Foreign Secretary: Mr. de Méric. Council: Dr. Althaus, Dr. Anstie, Mr. Barwell, Dr. Bird, Dr. Hullett Browne, Mr. Bryant, Dr. Camps, Mr. Canton, Dr. Cholmeley, Dr. Clarke, Mr. Weeden Cooke, Dr. Jephson, Dr. Leared, Mr. Poland, Mr. Robarts, Dr. Rogers, Mr. H. Smith, Dr. Abbotts Smith, Dr. Stocker, and Mr. Thompson. Orator: Dr. Smiles.

The annual oration was delivered by Dr. Thudichum.

THE PATHOLOGICAL SOCIETY.

Tuesday, March 15.

Mr. Prescott Hewett, President.

Dr. Wale Hicks read a report on his case of

CRANIA BIFIDA.

He had found that the sac protruded through the opening was formed of the tentorium cerebelli, and that under it was a communication with the left, but not with the left lateral ventricle.

In reply to the President, Dr. Hicks stated that there was no cerebral matter in the opening.

Dr. Wale Hicks also read a

REPORT ON A PORTION OF THE LUNG OF A HORSE EXHIBITED AT A PREVIOUS MEETING OF THE SOCIETY.

The portion of lung examined was found to be very slightly crepitant, and on being cut into small pieces some of them sank in water and others barely floated. On naked-eye inspection, it appeared to contain a quantity of greyish-white matter, filling up the spaces of the lung tissue. On microscopic examination, this whitish matter was found to occupy the air-cells, filling up most of them more or less completely. It was seen to consist of corpuscles, varying somewhat in size and shape, the predominant form being spherical. These corpuscles contained much granular matter, and many of them appeared to be nucleated.

Dr. Harley said that Dr. Quain had reminded him that the specimen on which Dr. Hicks had reported was very like one he (Dr. Harley) had received from the Veterinary College. On section the lungs presented innumerable white spots, looking at first sight like entozoa. When he received the specimen it so happened that no less than seven pathologists were present, and none of them had seen a similar condition in the lungs. They were removed from a young horse, four years of age. The animal had had good health until six weeks before death, when it began gradually to lose flesh. The appearance of the lungs being very unusual, they were sent from the country to the Veterinary College, but the professors there said they had never seen lungs in that condition. Dr. Harley looked for ova, but found none; but on microscopical examination found appearances similar to those Dr. Hicks described in his report, and he had no doubt the specimen was some form of cancer. Unfortunately, the other organs had been thrown away. Dr. Harley came to the conclusion that the cancer was secondary. Since examining this specimen he had received another nearly like it, but here there were masses of soft cancer in the spleen, and in the lung also were several large nodules, as well as the smaller ones found in the other specimen.

Dr. Wale Hicks said that in his specimen no distinct spots were found. The matter was uniformly infiltrated.

Dr. Quain suggested that Dr. Hicks should examine Dr. Harley's second specimen, and present a report upon it, and that it should be ascertained whether Dr. Harley's first specimen was not the one on which Dr. Hicks had just reported.

Dr. Murchison brought forward a specimen of

NECROSIS OF THE HYOID BONE.

A woman, thirty-five years of age, was first seen by Dr. Murchison in October, 1862. She had had loss of voice for some months, and a few days before had coughed up the piece of bone exhibited. There was ulceration of one tonsil, which extended to the root of the tongue, tenderness on swallowing and movement, and also grating between two ends of the hyoid bone. There was no evidence of syphilis. In August a smaller piece was coughed up. For ten months she was under observation, and grating could be readily felt. In September, 1863, she was seen again. Then the voice was good; the grating was not to be felt; but the two ends of the bone were still moveable.

Dr. Gibb said one interesting point in the above case was the absence of evidence of specific disease. He (Dr. Gibb) had collected nine cases, and in two, or, perhaps, three, only did he find distinct history of syphilis. The disease, he

said, began by acute periostitis; he then alluded to a case which he had successfully treated in this stage.

The PRESIDENT would not be certain that the bone was part of the hyoid, and he had doubts also as to the grating being anything abnormal. Some years ago a girl was admitted into St. George's Hospital for a diseased heel. She had a little tenderness over the larynx, and the Surgeon under whose care she was found grating. He considered this was evidence of disease of the larynx, and frequently drew the attention of others to the grating as a curious and rare symptom. The Surgeon was rather startled to hear from Mr. Gregory Smith, who saw the case, that grating on pressure of the larynx was normal. The patient died, and at the autopsy no disease of the larynx was found.

Dr. MURCHISON thought that if the President had seen the patient from whom the specimen was removed, he would have had no doubt as to its nature. He could take hold of each end and press them together: and this, too, was done by several observers. At first he fancied there might have been disease of the vertebræ, and that this might have been the source of the bone; but the symptoms were chiefly laryngeal, and the bone, on comparison with the normal hyoid, looked like a piece of that bone. Dr. Murchison said that if he could succeed in finding the patient he would send her to Dr. Gibb for laryngoscopic examination.

Dr. GIBB said that there could be no doubt that parts of the hyoid were coughed up. In one case the whole of the hyoid had been expelled.

Dr. GIBB was requested to examine and report on the specimen.

Mr. BARWELL brought forward a boy who had

A PECULIAR DISEASE OF THE TONGUE.

The tongue was fissured and in parts ulcerated. It began when the boy was four years old, but no cause could be ascertained. It followed a scratch on the upper lip. There was no evidence of syphilis, but the appearances in an adult would have suggested syphilis.

In reply to Dr. Crisp, Mr. BARWELL said he did not know whether the boy had been in the habit of eating coarse bread, and, in reply to Dr. Buchanan, that he did not know whether the boy had had any of the exanthemata.

Dr. QUAIN asked the President if he thought the appearance was disease, or merely a natural condition. He (Dr. Quain) knew a family in which several members had this peculiarity, and had often seen it in people who had no disease.

Mr. BARWELL remarked that the fissures might be natural, but that ulceration must signify disease.

The PRESIDENT said that from a cursory examination it seemed natural. He had often seen tongues looking like it, sometimes with ulcers and sometimes with clefts only.

Mr. BARWELL showed several

PHOTOGRAPHS OF CLUB-FOOT.

He brought them forward in order that he might speak on certain points in muscular pathology which had been touched on at a previous meeting. Mr. Barwell said that muscular fibre had two kinds of contractility—one directly dependent on cerebro-spinal stimulation, viz., active contraction; and the other a sort of elasticity, tonic contraction. The former was powerful and evanescent: the latter feeble, but constant. In the most severe affections of the nervous system there was no such thing known as continuous active contraction of muscles, so that it never occurs in nature that an active muscular contraction is either violent or continuous enough to produce permanent distortion. Mr. Barwell did not include deformities from assumed position or from disease of joints, but would take club-foot as an illustration of his views. This, he believed was due, not to active contraction of one set of muscles, but to paralysis, so that the tonic contractility of the opposite set produces the distortion. It was analogous to the distortion of the face in paralysis. Mr. Barwell thought that no sound judgment would admit that active contraction, which never produces non-congenital club-foot, would be a frequent cause of the congenital. He was rather surprised to hear Mr. Adams at a recent meeting say that he "could never find the slightest trace of paralysis in these cases," as he (Mr. Barwell) had found that there was in such cases a considerable loss of contractility under the electric stimulus. Had it ever, Mr. Barwell asked, occurred to the orthopædic mind that, to distort a foot by active contraction a muscle must act with such energy that, if its tendon were cut, the ends would fly asunder like arrows from a bow? Mr. Barwell was surprised to hear it stated that brilliant results in Orthopædism were obtained in paralytic cases. Apart from theoretical considerations, he must say that the amount of lameness he had found left after operation in these brilliant cases was extreme.

Dr. HENRY DICK said he could not agree with Mr. Barwell on the subject of cutting tendons. The history of subcutaneous tenotomy was very instructive. Before Delpech and Stromeyer cut tendons, club-foot was not curable. Venel, in Switzerland, made strong efforts, in the last century, to cure deformities by extension, and he rarely succeeded except in slight cases. Scarpa did know well the pathological anatomy of club-foot, and advised judicious instruments, but still club-foot was rarely cured, and it was only since the introduction of tenotomy that the treatment made any progress. The elements of the deformity are not only the muscles, but also the ligaments and fasciæ. To overcome these elements of the deformity, we are obliged to cut the tendons, and daily experience shows us that without cutting the tendons we cannot cure club-foot. Slight cases of club-foot or paralytic cases might do well without cutting. Dr. Dick always found that the action of the muscles after tenotomy was not weakened, and, as a rule, the patient gets a useful limb; so far experience was entirely in favour of judicious subcutaneous tenotomy.

Mr. ERNEST HART did not know if Mr. Barwell extended his views to the ophthalmic as well as to the orthopædic mind. The action of the muscles of the eye admitted of careful study and specialisation, and if Mr. Barwell would consider their condition in squint, both before and after operation, he would find that he had overstated his case.

Mr. BARWELL said, in reply to Dr. Dick, that there was no reason why club-foot should not now be cured without cutting tendons, because before Stromeyer began to cut them club-foot had never been cured at all. He knew, too, that instruments were used, without cutting, in the cure of club-foot, but he objected to them as much as he did to tenotomy. In reply to Mr. Hart, he said that he thought squint was more likely to be due to paralysis of the external, than to contraction of the internal rectus. If he could treat strabismus without cutting the tendon, he should prefer to do it; but it was impossible to treat the eye like the foot. We could not, he said, fix springs in the eye, but now and then we could cure strabismus without operation.

Mr. HULKE thought it would be doing an injustice to Donders, who had done so much in the investigation of strabismus and paralysis of the muscles of the eye, if he did not now mention that he had demonstrated the real cause of strabismus. In 95 per cent. the eyes of squinters were hypermetrophied. The squinting was not due to paralysis of the external rectus, but to undue convergence to increase the refractive power of the eyes. In slight cases of squint cure might be effected by spectacles.

Mr. BARWELL said that double squinting in such cases was analogous to the deformity which occurred from an assumed position.

Mr. HART thought that Mr. Barwell had not yet seized the point in question, that squinting was due to spasm, and not to paralysis.

(To be continued.)

EPIDEMIOLOGICAL SOCIETY.

The annual meeting of this Society was held on the 4th inst. A report was presented by the Council, which showed that the state of the Society, both generally and financially, was most favourable; and the following office-bearers for the session 1864-65 were elected:—

President: Dr. Gavin Milroy.—Vice-Presidents: His Excellency the Earl of Carlisle, the Earl of Shaftesbury, the Right Hon. W. Cowper, M.P., Dr. Babington, Dr.

Henry W. Acland, Dr. Alex. Bryson, Edwin Chadwick, Esq., Dr. Copland, Dr. Farr, Dr. J. Brown Gibson, Dr. Jenner, Sir J. Ranald Martin, Dr. Alex. Nisbett, John Simon, Esq., Sir Andrew Smith, M.D., Dr. Watson, Dr. Chowne, Dr. Murchison.—Foreign and Colonial Secretaries: Belgium and France, Dr. Waller Lewis; Germany and Russia, Dr. Hermann Weber and Dr. Swaine; Sweden, Norway, and Denmark, Dr. Gordon Latham; Portugal and the Brazils, Dr. Bryson. R.N.; Egypt and Syria, Dr. Camps; East Indies, Dr. James Bird; West Indies and North America, Dr. Dickson, R.N.—Treasurer: Dr. Camps. —Secretary for the Navy: Dr. Mackay, R.N. — General Secretary: J. N. Radcliffe, Esq.—Other Members of Council: Dr. Aldis; F. G. Burge, Esq.; Colonel Hough; Ernest Hart, Esq.; C. F. J. Lord, Esq.; Dr. Crawford; J. F. Marson, Esq.; Dr. Morehead; Dr. Odling; Dr. Richardson; Dr. Sanderson; Dr. Seaton; Dr. Hayward; Dr. Letheby.

After the election of office-bearers, Dr. Babington, on retiring from the chair which he has occupied for thirteen years, delivered an address on the "Origin, Present Position, and Prospects of the Society."

LEGAL INTELLIGENCE.

NORTHERN CIRCUIT.

FOX *v.* GLEDHILL—IMPORTANT TO THE MEDICAL PROFESSION.

Mr. Price, Q.C., and Mr. Maule were for the plaintiff; Mr. Seymour, Q.C., and Mr. Kemplay for the defendant.

The plaintiff, a mechanic at Halifax, brought his action against the defendant, a surgeon practising at the same town, to recover damages for having wilfully neglected his duty in the exercise of his Profession, whereby the plaintiff's wife died in childbirth. On September 30 last she with her mother-in-law waited upon the defendant at his residence, and he agreed to attend upon the plaintiff's wife during her confinement. Symptoms of approaching labour were manifest on December 8, and on the morning of the following day Mrs. Fox became so rapidly worse, that her mother-in-law waited on the defendant, and requested his immediate attendance. He declined, alleging as an excuse that he had to go down to the County Court, he having twenty cases to attend to, and if he were not present the judge would be angry with him. The mother-in-law returned, and when the plaintiff came home to dinner he was told the condition which his wife was in, and he instantly ran off for the defendant, who reluctantly consented to return with him to the house. The defendant then ordered the poor woman to be put to bed, some gruel to be given to her, but no brandy or any other stimulant. He told the plaintiff that his wife was "soft," and said that he should not be wanted for twenty-four hours, or perhaps three days or a week. The defendant then went away. At four o'clock next morning the plaintiff went to the defendant's house, and knocked loudly at the door. The defendant, who was in his night-dress, put his head out of the window, and the plaintiff told him to come down directly, as his presence was required immediately upon his (plaintiff's) wife. The defendant said that the woman was "soft," and if she went on in that way she would tire both him and the woman. They must be wrong in their heads to send for him in that manner. The plaintiff insisted upon the defendant seeing his wife, upon which he said if the plaintiff insisted he must go. On the road he remarked to the plaintiff that he was surprised at the woman, as they did not seem to study his comfort. Before they arrived at the house they were met by the plaintiff's brother, who informed him that the poor woman was dead. The defendant then expressed his regret at what had happened, and said he wished he had attended plaintiff's wife the night previous. In justice to the defendant, it ought to be stated that he has been in practice thirty years, has never been considered a negligent man, and his character for humanity and respectability has never before been called in question.

Mr. Seymour submitted, in defence, that his client had undertaken to attend the case when in his belief his services should be required. When he first saw the woman he found that she was going on slowly in the right way, and that there was nothing at the time to excite alarm. He ascertained that the confinement could not in all probability take place within twenty-four hours, and exercising careful judgment and skill he was justified in the conduct he had pursued. Had he been present previous to death he could not have saved the woman's life. The learned counsel contended that the defendant had not been guilty of any negligence or a breach of contract, that there was no proof of the actual cause of death, and that it might have arisen from some other cause than that of labour.

The defendant was called, and he stated that when he was waited upon he told the party that he had to attend the County Court, and requested that another Medical man might be engaged. He saw the plaintiff at eight o'clock at night, and then requested him to send before ten if his services should be required. No person came, and soon after twelve he went to bed, and was not aroused by the plaintiff until nearly five o'clock next morning. He entirely denied any reluctance to attend the case, and also denied making use of the unkind remarks attributed to him. It was not improbable that disease of the heart might have caused the death of the plaintiff's wife. Verdict for the defendant.

DEATHS.

Beaumont.—On the 31st ult., James Beaumont, Surgeon, of Wetherby, aged 75.

Biddle.—On the 5th inst., at the Dispensary, Leeds, Henry, son of Charles H. Biddle, M.D., aged 10 months.

Colby.—On the 22nd ult., suddenly, at Bayswater, T. T. Colby, Surgeon.

Colligan.—On the 2nd inst., at Johnstone, Paisley, W. W. Colligan, L.R.C.S.Ed., aged 31.

Headley.—On the 15th ult., at the Lincoln Lunatic Hospital, W. C. Headley, Surgeon, aged 82.

Henderson.—On the 31st ult., at Belgrave terrace, Lee, Kent, J. Henderson, R.N., Deputy Inspector-General of Hospitals and Fleets, July 25th, 1855, late Surgeon at Portsmouth Dockyard.

Hildyard.—On the 30th ult., J. G. Hildyard, M.R.C.S.E., of Louth, Lincolnshire, Consulting Surgeon to the Louth Dispensary.

King.—On the 29th ult., G. H. King, M.B., of Horncastle, Lincolnshire, aged 40.

Taylor.—On the 29th ult., at the Grand Hôtel du Louvre, Marseilles, W. C. Taylor, late Surg-General Army Medical Board, Bombay, aged 61.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 31st ult.:—William Reuben Booth, Great Queen street, S.W.; Walter Tawell Colman, London Hospital; Eugene St. Paul Hadwen, Waterloo road, S.; John New Moore, Moreton-in-Marsh; Lyttelton Frederick Osbaldeston, Hatfield, Herts; Philip George Philps, Westbourne-park road; George White, Thatcham; William Samuel Wilson, Hereford road North, Bayswater.

The following gentlemen and lady also on the same day passed their first examination:—George Arthur Brown, King's College; Edward Charles Evans, King's College; Elizabeth Garrett, 22 Manchester square; John Thomas Langley, St. Bartholomew's.

University of Edinburgh.—In order to honour and perpetuate the names of the individuals who have founded scholarships, bursaries, and new chairs in the University, and other eminent members who have contributed to the usefulness and reputation of the institution, the Senatus Academicus have made arrangements for placing busts or portraits of them in the library or University Court-room. Several are already placed, and it is intended to make as large a collection as possible. Amongst them will be found Dr. Muir, Mr. Patrick, Dr. Cullen, Dr. Black, Dr. James Gregory, and Sir Charles Bell.

BETHLEHEM HOSPITAL.—On Saturday an adjourned special meeting of the Governors of Bethlehem Hospital was held at Bridewell Hospital, Bridge-street, Blackfriars, under the direction of Mr. F. O. Martin, Inspector of Charities, respecting the site of the hospital; Mr. Alderman Copeland, M.P., in the chair. The chairman said the Commissioners in Lunacy having recommended to Sir G. Grey that the hospital should be removed from its present site to the country, to make room for St. Thomas's Hospital, the Governors were prepared with a great deal of evidence which they should offer to Mr. Martin in favour of the present site. Mr. A. M. Jefferson (the secretary) read a communication from Mr. Lawrence, surgeon to the hospital, and senior surgeon to St. Bartholomew's Hospital, which stated that the Commissioners in Lunacy sought to obtain the assistance of Sir George Grey in order to enforce an arrangement which was most repugnant to the Governors, forgetting that their powers, as far as Bethlehem was concerned, was simply confined to that of visiting. Without any examination on his part, the Home Secretary endorsed the strange proposal for taking down one of the handsomest and best constructed hospitals in London. The present site of Bethlehem was perfectly suited in healthiness either for lunatics or as a general hospital. Instead of being confined, the site of the hospital was remarkably open. He disapproved entirely the recommendations of the Commissioners in Lunacy. The opinion of Dr. Goode was read. He was in favour of the present site from his personal experience of 10 years. At present it enjoyed many advantages, and the hospital, instead of being hemmed in by buildings, was peculiarly free and open. If the hospital was removed 10 or 20 miles into the country, how were the patients to be removed to the hospital? The sanitary condition of the neighbourhood was good. The site was healthy, and the position good, and he hoped that the hospital would be maintained in its present condition. Dr. Wood, one of the medical officers of St. Luke's Hospital, and formerly of Bethlehem Hospital, said no good reason had been advanced why the hospital should be removed. Bethlehem was one of the finest buildings in London, and taking the grounds of Bethlehem, with its 11 acres and 200 patients, and Hanwell, with 28 acres, farm of 77 acres, and 1,600 patients, there was considerably more space at Bethlehem per head than at Hanwell. The hospital was singularly and exceptionably healthy. When cholera was raging in London, and people were dying literally at the very doors of the hospital, not a single case happened among the inmates. Mr. Martin, the inspector, asked whether it was possible to have an institution in the country in connection with the hospital. Mr. Johnson, the treasurer, said, to a small extent, they had already sent patients to the seaside. After some further evidence had been taken, a vote of thanks was passed to the chairman, and the meeting was adjourned.

THE INDIAN MEDICAL SERVICE.—The first move has been commenced (says the 'Hurkaru'), towards removing the officers of the company's Medical service from the charge of the new line regiments of cavalry and infantry; and the new brigade of Royal, late Indian artillery, and for the transfer of all those regiments and brigades to the Medical charge of officers of her Majesty's British forces. The principal Medical officer of her Majesty's British forces here has addressed a circular to all Medical officers of her Majesty's British army arriving in the country, calling upon them to apply for employment with the new corps, and to state what regiment and station they desire, for his information. It was of course known that the change would form part of the new scheme for restoring the Indian Medical service; and that, contemporaneous with its promulgation, the Medical officers of that service would lose all charge of, or connection with, British regiments; but here we see the deprivation of the best and most coveted Medical charges in India meted out to the Medical officers of the late company's armies, and the substitution of no advantages in their stead. Perhaps, however, we are justified in assuming that this movement is a shadow cast closely before the coming measure for reorganising the Indian Medical Service; and that before the company's officers shall have been totally ousted from the charge of the new line regiments, other provision will have been made for them.

NORTHAMPTON GENERAL LUNATIC ASYLUM.—It is intended to erect a new building for the reception of the county pauper lunatics.

HIS MAJESTY KING VICTOR EMMANUEL has presented a sum of 12,000*l.* to the City of Naples for the erection of a civil hospital.—'Journal of Practical Medicine and Surgery.'

SEVERAL cases of death among cattle, and especially among horses, have recently occurred in Normandy, from the animals having fed on the leaves of the yew-tree. The poisonous qualities of this plant were well known to the ancients.—'Ibid.'

MR. RAYER, President of the Association of French Practitioners, and Mr. P. Andral, the legal adviser of that body, had an audience on the 19th of March, of the Minister of Justice. The illegal practice of medicine in the Département de la Gironde, and the insufficient amount of the fee allowed to medical men, were pointed out to the Minister, who promised to take the report of the Medical Association into consideration.—'Ibid.'

DR. LIVINGSTONE.—Her Majesty's steamer Rapid has arrived at Table Bay from the eastern coast of Africa. She brought the welcome intelligence that Dr. Livingstone was alive and well. On the 5th of January the Rapid arrived at the Louba mouth of the Zambezi, expecting to find Livingstone and his party, to take them on to the Cape. On communicating with the Portuguese station house there they found there was a letter addressed to the senior naval officer from Bishop Tozer. It was dated "Murchison Falls, December 21," and stated that Dr. Livingstone had come back from his expedition up country, and arrived at the foot of the Murchison Falls in November, and they intended to come down the river as soon as the water rose sufficiently to get the Pioneer down. Dr. Livingstone, the Bishop, and party were well in health. The mission party also intended to leave the country, as it appeared an unsuitable field, and would return to England by the Cape; the Bishop and one of his clergymen, however, were to go and visit the Governor of Mozambique. There were no letters for the Cape. The Rapid brought down 187 prize negroes taken from a slaver.—'Graham's Town Journal.'

KEW GARDENS.—Sir W. J. Hooker has, of course, to report a smaller number of visitors at Kew in 1863 than in the Exhibition year. Still, they exceeded 400,000. On one Sunday there were 12,441, and on one week day 11,631. The number of scientific visitors and of persons frequenting the Museum and Palm house for purposes of instruction has increased. Many improvements in the gardens are in progress or contemplated. The duties of the Department of the Herbarium are rapidly increasing, owing to the demands made upon it by various departments of the Government, the receipt of large collections from important Government expeditions, the applications for advice from persons proceeding to take charge of plantations of tea, cinchona, cotton, coffee, &c., and the redoubled activity of the colonies in the publication of their 'Floras,' which, though paid for by the Colonial Government, can only be prepared at Kew, or by persons in direct and constant correspondence with its Herbaria and Museums. The 'Flora' of the British possessions in India is to be proceeded with upon the same plan as the colonial 'Floras,' and has been commenced in the Herbarium by Dr. Thomson. Very satisfactory reports are received of the success of the introduction of cinchona plantations in India, in the establishment of which Kew has had so large a share. In the nurseries on the Neilgherrie hills there were, in December last, nearly 260,000 plants, of which more than 66,000 were planted out; one was nearly ten feet high. The bark has been analysed, and the result is entirely satisfactory. There are 8,000 plants in the Darjeeling plantation, Himalaya, and 22,000 in Ceylon. Steps have been taken at the request of the Government of South Australia to introduce the cork tree into that colony; a large quantity of young plants have been

raised in the pleasure ground nursery for transport, to be sent out this spring in a growing condition in glazed cases. Large collections of semi-tropical trees and shrubs have been sent, at the request of the Admiralty, to the once desert island of Ascension, the upper parts of which are now clothed with trees and shrubs, chiefly derived from Kew. The most satisfactory accounts are received of the thriving condition of these plants, and the consequent rapid increase of the fertility, water supply, pasture land, and vegetable produce of the island. The Bermuda grass especially, which was sent from Kew several years ago, has now become the staple fodder of the place.

CHARGE OF NEGLECT AGAINST A SURGEON.—The Board of Guardians of Newton Abbott have been occupied in the investigation of a charge of drunkenness and neglect preferred against Mr. Sparham, surgeon, of Newton Abbott. We are happy to say that after a full inquiry the Board resolved "that Mr. Sparham leaves the room without a stain upon his character."

THE ROYAL MEDICAL BENEVOLENT COLLEGE.—Miss Margaret Good (daughter of the late eminent Dr. Mason Good), has bequeathed to the Royal Medical Benevolent College the sum of 250*l.* free of duty.

BRADFORD EYE AND EAR INFIRMARY.—The foundation stone of an Eye and Ear Infirmary was laid on the 29th ult., by Titus Salt, Esq., the mayor of Bradford. The origin of the institution is due to Dr. Bronner, who devoted his time gratuitously to the undertaking, and about six years since the present building was opened. The increasing demand for relief has rendered further accommodation necessary, and the exertions of the committee have resulted in the building of a new infirmary. It will be of the early Gothic style, one hundred feet in length, sixty feet in width, and five stories high. The total cost will be about 5,500*l.*

MESSRS. DEMARQUAY AND LECOMTE have recently laid before the Institute the results of their inquiries on the therapeutic effects of the inhalation of oxygen. This gas is a powerful stimulant of the circulation, and should not be exhibited to persons labouring under disease of the heart, or threatened with hæmorrhage, or inflammation. But it is appropriate in anæmia, and in general in every morbid condition in which it is desirable to invigorate the system.—'Journal of Practical Medicine and Surgery.'

THE profession in France mourns the loss of Dr. Bailly, of Dr. Paris, of Dijon, and of Dr. Landouzy, whose researches on the subject of pellagra are well-known to our readers. Dr. Gallice, of Langeac, who, despite previous illness, travelled some distance to visit a patient, perished in the snow, on the 20th of February, a victim to his unflinching sense of duty.—'Ibid.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, APRIL 13.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.

THURSDAY, APRIL 14.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, APRIL 15.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, APRIL 16.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, APRIL 18.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, APRIL 19.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Science and Art of Surgery. By J. E. Erichsen, F.R.C.S., &c. Fourth Edition, enlarged and revised. London: Walton and Maberley, Upper Gower street, W.C.

Notes on the British Pharmacopœia, showing the Additions, Omissions, Changes, &c. By A. F. Haselden, Pharmaceutical Chemist. London: R. Hardwicke, 192 Piccadilly.

The Classification of Skin Diseases. By W. Tilbury Fox, M.D., &c. London: R. Hardwicke, 192 Piccadilly.

The Principles of Surgery; Clinical, Medical, and Operative. By F. J. Gant, F.R.C.S., &c. London: J. Churchill and Sons, 11 New Burlington street.

On the Advantages derivable to the Medical Profession and the Public, from the Establishment of Village Hospitals, with General Instructions concerning costs, &c. By A. Napper, M.R.C.S., &c., Founder of the System. London: H. K. Lewis, 15 Gower street, North.

The Hunslet Poor-law Inquiry into the Conduct of the Master and Surgeon, conducted by U. Corbett, Esq., the Inspector appointed by the Poor-law Board. Leeds: E. Baines and Sons.

The Ophthalmic Review, a Quarterly Journal of Ophthalmic Surgery and Science. No. i. London: R. Hardwicke, 192 Piccadilly.

The Medical Mirror. No. IV. London: H. K. Lewis, 15 Gower street, North.

The Elements of Comparative Anatomy. By T. H. Husdey, F.R.S. London: John Churchill and Sons, New Burlington street.

Second Annual Report of the Cumberland and Westmoreland Lunatic Asylum.

The Canada Lancet. No. 13.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

Mr. PROWSE's letter is inserted, and the cause he advocates has our best wishes.

T. L. GALVANI.—We are not aware whether the information required is to be found in the work alluded to, but it is contained in Dr. Althaus's book lately published (third edition), on Paralysis, Neuralgia, &c., treated by Galvanisation and Faradisation.

Mrs. B.—The extract has been received.

THE PHARMACEUTICAL SOCIETY.—The cards have been received.

Mr. HENRY SMITH is thanked for his letter, and our reviewer will be grateful in being corrected for seeming to commit an unintentional act of injustice towards two distinguished surgeons.

PHILOMATHES.—Trichina is derived from the Greek word θριξ, τριχος, a hair, and is so called from its minute and threadlike structure. It is a parasite belonging to the nematoid entozoa.

TYRO.—When menstruation occurs during lactaction, the milk of the nurse undergoing certain alterations produces in the child temporary derangement of the stomach and bowels. The changes in the milk are these: its quantity is diminished—if the "loss" be great it may be altogether checked—and it sometimes approaches the character of cow's milk, being, in fact, increased in richness; its globules are increased in size as well as in number. According to MM. Becquerel and Vernois, the density is slightly diminished, as are also the quantity of sugar and water; while there is a very sensible increase in the solid constituents, especially the casein. M. Roger states that, if she menstruate, lactation not having been continued longer than twelve or fifteen months, and if the menstrual functions be naturally performed, no change takes place in the milk either as regards its quantity or quality. The fact of the menses appearing at an advanced period of lactation, augurs that the proper time for the cessation of this latter has arrived, and should be accepted by the woman as the signal of injury to herself and to the child if the suckling office is continued.

Q. C., "BLENORRHAGIA."—By this term is understood the local inflammation which results from specific venereal contagion; chancre is different, inasmuch as there is solution of continuity in the soft structures, with loss of substance, which loss of substance, attended by a discharge, varying in different cases as regards its quantity, and also by a slight blush or halo of inflammation and inflammatory redness, receives the name of ulcer (chancrous or venereal). Ricord, Porter of Dublin, and others believe blenorrhagia to be incapable of occasioning constitutional syphilis.

University College, London. —

FACULTY OF MEDICINE.—The SUMMER TERM will commence on MONDAY, MAY 2nd.——CLASSES (in the order in which they meet)—

Practical Surgery.—Mr. Marshall, F.R.S.	7½ a.m.
Materia Medica and Therapeutics.—Professor Ringer, M.D.	8 ,,
Pathological Anatomy.—Professor Wilson Fox, M.D.	9 ,,
Medical Jurisprudence.—Professor Harley Harley, M.D., F.C.S.,	10 ,,
Practical Chemistry.—Professor Williamson, F.R.S.	11 ,,
Midwifery.—Professor Murphy, M.D.	12 noon.
Palæo Zoology.—Professor Grant, M.D., F.R.S.	3 p.m.
Botany.—Professor Oliver, F.R.S., F.L.S.	4 ,,
Ophthalmic Medicine and Surgery.—Professor Wharton Jones, F.R.S.	(Hour to be fixed.)

Hospital Practice.—Daily.

Medical Clinical Lectures.—Professor Jenner, M.D.; Professor Hare, M.D.; and Professor Reynolds, M.D.

Surgical Clinical Lectures.—Professor Quain, F.R.S., and Professor Erichsen.

Clinical Lectures on Ophthalmic Cases.—Professor Wharton Jones, F.R.S.

Practical Instruction in the Application of Bandages and other Surgical Apparatus.—Mr. Marshall, F.R.S.

Practical Pharmacy.—Pupils are instructed in the Hospital Dispensary.

Prospectuses may be obtained at the Office of the College.

WM. SHARPEY, M.D.,
Dean of the Faculty.
CHAS. C. ATKINSON,
Secretary.

April 2nd, 1864.

Royal Medical Benevolent College.—

The Council have the pleasure to announce that SIR CHARLES LOCOCK, Bart., M.D., has kindly consented to take the chair at the TWELFTH ANNUAL FESTIVAL of the College, which will take place at Willis's Rooms, King street, St. James's, on Saturday, the 14th of May next, when it is earnestly hoped that there will be a large meeting of the friends of the Institution.

The following gentlemen have already undertaken to act as Stewards on the occasion, and a further list will be published shortly. Gentlemen willing to serve are requested to forward their names to the Treasurer, John Propert, Esq., 6 New Cavendish street, W. There is no liability attached to the office.

The Rt. Hon. The Earl of Shaftsbury, K.G.
Sir Edmund Filmer, Bart., M.P., Eaton square.
Sir Walter Stirling, Bart., Portman square.
Sir John W. Fisher, M.D., Grosvenor gate.
The Master of Trinity Hall, Cambridge.

Acland, H. W., M.D., F.R.S., Oxford.
Aldis, Cearles, J. B., M.D., Chester terrace.
Angerstein, William, Esq., M.P., Woodlands, Blackheath.
Astell, John Harvey, Esq., M.P., Upper Harley Street.
Barnes, Christopher H., Esq., Bellevue House, Notting hill.
Barringer, Thos. C., Esq., St. John Street.
Billing, Archibald, M.D., Grosvenor gate.
Bowman, William, Esq., F.R.S., Clifford street.
Brodhurst, Bernard E., Esq., Grosvenor street.
Brown, Isaac Baker, Esq., Connaught Square.
Budd, George, M.D., F.R.S., Dover Street.
Fuller, H. P., Esq., Stoke Poges.
Chapman, Joseph, Esq., Hounslow.
Cooper. W. White, Esq., Berkeley Square.
Cory, Frederic C., M.D., Nassau place.
Critchett, George Esq., Harley street.
Du Pasquier, Cladius F., Esq., Pall mall.
Erichsen, John E., Esq., Cavendish place.
Garrett. Charles B., M.D., Hastings.
Gay, John, Esq., Finsbury place South.
Gream, George T., M.D., Upper Brook street.
Gull, William W., M.D., Brook street.
Hands, Benjamine, Esq., Hornsey.
Hankey, Thomson, Esq., M.P., Portland place.
Harcourt, George, M.D., Chertsey.
Harrison, William A. Esq., Keppel street.
Harvey, William, Esq., Soho square.
Hatfield, Richard, B., M.D., Cleveland Street.
Hawkins, F. Bisset, M.D., F.R.S., Upper Harley street.
Hawkins, Charles Esq., Savile row.
Haycock, W. Hine, Esq., Charterhouse square.
Hewett, Prescott G. Esq., Chesterfield street.
Kendall, T. Marsters, Esq., King's Lynn.
Locock, Charlas Brodie, Esq., Cambridge square.
Lyall, George, Esq., M.D., Headley Park, Epsom.
Murdoch, James, Gordon, Esq., Gt. Berkhamsted.
Peter, R. H., Esq., North Bwnk, Regent's Park.
Pitman. Henry A., M.D., Gloucester place.
Reed, F. G., M.D., Hertford street,
Rodocanachi, M. E., Esq., Gloucester square.
Sankey, William, Esq., Dover.
Seymour, Edward J., M.D., Charles street.
Smith, Protheroe, M.D., Park street.
Smith, T. Heckstall, Esq., St. Mary Cray.
Solly, Samuel, Esq., F.R.S., Savile row.
Thompson. Henry, Esq., Wimpole street.
Tothill, F. D., Esq., Charles street.
Waggett, John, M.D., Kensington Park.
Walker, Colonel Geddes, United Service Club.
Waters, John, M.D., Bedford square.
Wood, William, M.D., Upper Harley street.

By order of the Council,
ROBERT FREEMAN Secr ta .

Office—37 Soho square, W.,
April 7th, 1864.

The Medical Baths and Fumigations·

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible, or have altogether failed in effect. Imitations having arisen, be particular in the address.

Quinine.—The Medical Profession

—the LANCET—Dr. Hassall, and others recommend "Waters' Quinine Wine" as an excellent and simple stimulant. Manufactured only by ROBERT WATERS, 2 Martin's lane, Cannon street, London, E.C. Sold by Grocers, Italian Warehouse men, and others, a 30s. a dozen.

Wholesale Agent, E. Lewis & Co., Worcester.

Vaccination. Liquid Vaccine

LYMPH, in purity and source guaranteed, in Capillary Glass Tubes, hermetically sealed, which preserves it for any period, supplied to the Profession by Mr. FAULKNER, M.R.C.S., Operative Chemist, &c., Endell street, Long acre, London, W.C. Three Tubes sent by return of post, with instructions, on receipt of 30 stamps.

Lichin Islandicus, or Iceland Moss

COCOA.

Strongly recommended by the Faculty.

See Testimonials of Dr. Hassall, Dr. Normandy, with others To be had everywhere, at 1s. 4d. per lb.

Manufactured by
DUNN AND HEWITT, LONDON

BASS'S EAST INDIA PALE ALE.

This Season's Brewings of this cele-

brated ALE are now arriving in Casks of 18-gallons and upwards. Our stock of Ale in Bottles is in good condition. Barclay's Porter and Stouts, in bottle and cask, and Devonshire Cider may also be had of

BERRY BROS. & CO., 3 ST. JAMES'S ST., LONDON.

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared

in a GRANULAR and EFFERVESCENT Condition the Constituent of the following MINERAL SPRINGS:—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT, &c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER:—
GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS:—
GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.
GRANULATED AND EFFERVESCING CITRATE OF QUININE.
GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in

addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.

143, NEW BOND STREET, LONDON.

Anatomy, Physiology, Pathology,

and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.—

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Emperor Life and Fire Assurance

SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

EBENEZER CLARK, JUN., SEC.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By Robert Hunter Semple, M.D.,
Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 228.)

The Alterations in the Sounds of the Heart.—Morbid Sounds or Murmurs.—The presence of morbid sounds in the region of the heart, or over the course of the vessels, has always been regarded with great interest, because these phenomena often denote important structural disease. But, nevertheless, it would be a serious error to suppose that these sounds are always caused by appreciable alteration of structure, or that they always exist when mere anatomical reasoning would lead us to expect their presence. Although they very often accompany or denote pathological changes in the region of the heart or the vessels, yet it is constantly found that no appreciable lesion can be detected after death in cases where these sounds have been heard, and, on the other hand, morbid conditions of the heart have been discovered after death, when no abnormal sounds were detected during life. Facts like these, evidently puzzled Laennec, to whom is unquestionably due the discovery of the sounds designated by him *bellows sound*, *rasp* and *sawing sound*, and *musical* or *whistling sound*; but who was so little impressed with their pathological signification, that he declared that "among all the phenomena which have been discovered by mediate auscultation, these alone (the bellows, rasp, sawing sounds, &c.), are not associated with any organic lesion in which it is possible to discover their cause;"* and he goes on to state that he has traced many cases, both of acute and chronic disease, which presented the bellows murmur during the latter periods of life, and sometimes for several months, in a very obvious degree, both in the heart and arteries, but in which, after death, he failed to discover any organic lesion which constantly coincided with the sounds, or which were not frequently met with in cases in which the sounds were never heard. He at first considered the bellows sound of the heart to be a sign of contraction of its orifices, but he abandoned this idea by observing that it frequently existed where no such contraction was subsequently discovered, and on the other hand by finding ossification of the valves, the existence of which had never been announced by this anomalous sound. It was reserved for the followers of Laennec to trace out the real value and signification of the sounds, which he was the first to discover and to announce to the Medical world.

The fact is, that the abnormal sounds of the heart have a very deep significance in most cases, and their presence always points to some morbid condition of the heart itself, or of the vessels, or of the blood, or of adjacent structures or organs. Thus they may be due to obstructions existing at the orifices of the heart, or to imperfect closure of the valves, or to active inflammation outside the heart, or to an impoverished condition of the blood, or to the effects of mechanical pressure. Speaking generally, it may, perhaps, be said that they are always due to *friction*, which indeed in a philosophical sense occurs in all the actions and motions of the solids and fluids of the body, but which, in the healthy state, is diminished by the natural fluids poured out upon the internal membranes. In morbid states of the heart this natural friction becomes abnormally exaggerated, either by the presence of tumours or excrescences, or exudations developed from the solid parts, or by the passage of unhealthy fluids over healthy solid structures. Thus, however loud or well-marked may be the morbid sounds developed by inflammation of the pericardium, or disease of the aortic valves, they may be equally loud, or perhaps louder, when an attenuated blood passes over healthy valves, or through healthy vessels, as in chlorosis and anæmia, or even in a case where a large quantity of blood is suddenly abstracted. The sounds may also be artificially produced by pressure upon a large vessel.

The morbid sounds of the heart are usually called *murmurs*, whatever may be their cause or their seat, and as they resemble various well-known sounds, they have received the appropriate names of bellows-murmur, sawing, rasping, filing murmur, friction sound or murmur, new leather sound, &c. With regard to their situation, they are sometimes exocardial, or situated outside the heart; sometimes endocardial, being due to various conditions of the valves; sometimes they are seated in the arteries, sometimes in the veins. It may be thought at first sight that it is sufficiently easy to distinguish between a friction murmur outside the heart, and due to an affection of the pericardium, and one situated in the interior of the organ and connected with the valves; but the distinction is by no means so easy as it appears, a circumstance which may be accounted for by the remark made above, that all these morbid sounds are really due to friction of some kind. Skoda, in fact, whose views on auscultation are marked by strong originality, says, "I know no sign by which the friction sounds of the pericardium can be distinguished from the internal murmurs of the heart, excepting this, that the internal murmurs correspond pretty exactly to the rhythm and to the natural sounds of the heart, while the pericardial friction-sounds seem to follow upon the movements of the heart. This distinctive sign is only available when the murmur is somewhat prolonged; if it be of short duration, we cannot determine whether it is endocardial or exocardial."*

The following diagnostic distinctions (some of which are, however, of a rather recondite character) between pericardial friction sounds and endocardial murmurs, are laid down by Barth and Roger, although it is probable that the diagnosis in such cases will chiefly depend upon a careful examination of all the collateral circumstances. The bellows murmur is often heard at the origin of the great vessels, while the friction sound, when it is limited, is generally seated lower down towards the apex of the heart; the bellows murmur appears more deeply seated, and does not change its position, while the friction sound is more superficial and peripheric, and may change its place, being one day more marked on the right side, and another day on the left; the bellows sound is most commonly simple, and always associated with the same period of the heart's action; the friction sound is generally double, and when single, is less exactly synchronous with that one of the two sounds to which it belongs; the bellows murmur is often prolonged into the carotid arteries, but this is never the case with the friction sound, and, lastly, the permanent bellows murmurs are scarcely ever subject to any but slight variations of intensity, and if they change their character, it is only after long intervals, while the transformations of the friction sound are generally much more rapid.†

No great practical evils, however, can result from the difficulty of distinguishing in all cases between an exocardial and an endocardial murmur, because the former can exist only in acute cases, while the latter may be common to acute and chronic cases alike, and it must also be borne

* 'Traité de l'Auscultation Médiate.' Par M. Andral. T me III, p. 70.

* Skoda. A treatise on 'Auscultation and Percussion.' Translated by Dr. Markham, p. 219.

† Barth and Roger. 'Traité Pratique d'Auscultation.' Quatrième Edition, p. 466.

in mind that the bellows murmur and the friction sound may exist simultaneously in many cases of acute disease, while a persistent murmur can be caused only by chronic disease *within* the heart.

(To be continued.)

HOSPITAL REPORTS.

KING'S COLLEGE.

OPERATION BY MR. FERGUSSON.

On the occasion of our last visit the first patient submitted to operation was a young girl in whom cleft palate existed. About three years previously Mr. Fergusson had operated on her for the same deformity, and, according to his wishes, had succeeded in obtaining union of part of the fissure, a very small portion of the division being left for future operative measures.

The head of the patient being thrown well back, and the mouth opened as widely as possible, so as to expose to view the entire upper arch of the mouth, Mr. Fergusson proceeded by means of the knife especially constructed for this procedure, to dissect away the soft from the hard palate on each side of the fissure. For this step two knives were necessary, the one being larger than the other, in order that the fleshy palate might be the more freely detached from its bony connection.

The margins of the cleft in the palate having been made raw, and the soft palate having been sufficiently separated from its bony floor to allow the edges to lie in complete and easy apposition, a needle—the eye of which is at the point—armed with a *white* silk ligature, was passed through the left flap of the palate from below upwards, and from right to left, that is, from the right hand of the operator towards his left The operator stands on the right of the patient, not directly in front, because by taking up this latter position spectators are unable to see the steps of the operation, and very frequently the surgeon will be in his own light The needle's point and the ligature having traversed the left flap of the palate in the manner just described, the loop of the thread is seized by a forceps and held securely while the needle is being withdrawn. Another needle of the same description as that first employed, is armed in the same manner with a blue ligature, and passed from the operator's left to his right hand, that is, through the right flap of the divided palate in a direction from below upwards, and from without inwards, towards the median line of the body; the second thread being treated similarly to the first, and the needle by which it was armed having been withdrawn, the second thread is passed through the loop of the first ligature, and thus, as the former is withdrawn, the latter is brought through the right flap of the palate; the loop of it—the first or white ligature—is then uncoiled, so that while one extremity is retained in the left flap, the other, by means of the blue ligature is made to occupy the right. Both ends being now brought out through the mouth, a running knot is made on one extremity of the thread, through which the other extremity is passed, and the knot being then drawn down to the edges, as they lie in even apposition, is secured, a double knot being made besides. The aperture in the palate of the patient before us was a small one, and therefore, only required a single thread.

Mr. Fergusson adduced the present case as an example of the comparatively imperfect speech enjoyed by a patient, though the cleft in the palate had united as well as could be desired, and the roofed arch of the mouth had assumed, since his first operation, a shape and position calculated to improve intonation of the voice and articulation, if not to have altogether removed any imperfection; nor could he assign any reason for the continuance of such imperfections. The patient besides was most anxious for the success of the operation as regarded her speech, and gave every assistance in her power, that would tend to such an end.

Mr. Fergusson dwelt upon the comparative facility with which cleft palate united, when the arch of the palate was high and the angle formed at its mesial line was acute rather than very obtuse; in the latter case, it is sometimes a matter of no little difficulty to procure complete and permanent union.

This circumstance may be explained by the fact that the bones—in the instance of a very concave roof to the mouth—fall down towards the mouth, and thus allow an approximation of their separate margins. The bones themselves will often unite, when the fissure in the soft structures has been closed.

In the denudation of the edges of a fissure like the one now before us, Mr. Fergusson prefers merely to scrape them, and so make them raw; he does not at all approve of the plan of removing a ring of the tissues immediately surrounding the cleft, because such a procedure renders the union more difficult, and should failure attend our operation, the chasm is greater than before, also this step, in perhaps not a few cases, leads to failure.

There is no analogy between this step of the operation and a similar one in which the skin is concerned; for, of the latter tissue, there being usually a redundancy, there is some to spare, and which can be easily dispensed with, whereas, of the structures entering into the composition of the palate, there is not this same redundancy.

In some instances of this malformation, it will be expedient to make incisions on each side of the fissure, so as to permit the pared margins to come more closely together. This is requisite when there is tension of the parts. The incisions must, of course, be external to the points of insertion of the ligatures. There are certain varieties in the steps of this operation of staphyloraphy which we shall mention:—Some, before denuding the margins of the fissure, would strip up the soft from the hard palate, while others again reverse this order; a scissors or a knife, according to the custom of the surgeon, may be used in the paring of the edges of the soft palate; the lateral incisions into the soft palate may be made before the denuding of the edges, or after it; and a blunt or sharp-pointed knife may be used in the paring or scarification of the edges; the threads may be introduced before any incisions whatever are made; the needles may be those ordinarily used in uniting wounds, &c., and may be introduced from above downwards, instead of from below upwards.

Mr. Fergusson thus teaches respecting the usual form of split palate:—"The patient should be seated in a good light, and his head should rest on the breast of an assistant: the surgeon should then seize the portion of the uvula on one side of the fissure with a long hook-beaked forceps, draw it slightly forwards, and then carry a probe-pointed bistoury from the posterior border of the velum to the anterior part of the fissure in the soft palate, so as to make a clean-cut raw surface on its margin; then the other surface should be treated in the same way, or, by seizing the margin about the middle of the cleft, it may be held firmly until the knife, which, for this purpose, should be sharp-pointed, is pushed through and run backwards and forwards; next, a needle set in a handle, armed with a thread of the ordinary size for interrupted suture, should be passed from below upwards on one side of the cleft about a quarter of an inch from the margin; the thread, being seized with forceps, one end of it should be pulled forwards; the needle should now be withdrawn, threaded with another ligature, and then pushed from below upwards on the other side of the fissure at the same distance from its cut surface, when the thread should again be extricated with the forceps, and the needle at the same time withdrawn; one of the ends thus brought to the mesial line should then be attached to the other end, and by drawing either the one or the other through the opposite side, it will be found that a double thread, which can readily be made single by pulling out one of the ends, has been carried across the gap; two, three, or perhaps four threads being introduced in the same manner, each should be tied

in such a way as to keep the edges in close approximation, and the ends being cut off, the operation is accomplished."

It is not at all necessary that the starvation plan of treatment should be put into practice in the case of these patients; rather is such prejudicial, since it retards the union of the opposed surfaces. The experience of most surgeons, if not indeed of all, tends to show that such treatment is contra-indicated, and that it is far more wise to allow the patient a sufficiency of nutriment in a liquid form, and, in some instances, to administer wine or other stimulants. Solid food should not be allowed until all danger of rupture of the newly-joined parts is quite removed, and the junction seems sufficiently strong to permit free motion and compression on the part of the soft palate; indeed, it is needful that as far as possible all dragging upon the stitches should be obviated.

Some advise the removal of the threads upon the second or third day; Mr. Fergusson, however, states, "in many cases I have for years been in the habit of leaving the stitches in for six, eight, or ten days with seeming advantage."

It will be remembered that in the year 1844 Mr. Fergusson proposed and carried into practice the division of the palato-pharyngei, the palato-glossi, and the levatores palati. The following are the words in which he describes the mode of procedure, advised and adopted by him:—"Previous to paring the edges of the cleft, a knife—specially constructed for this operation—is passed through the fissure, so that its point can be laid on the tissues immediately above the soft velum, midway between its attachment to the bones and the posterior margin, and about half way between the velum and the lower end of the Eustachian tube; the point is then thrust deep, and carried half an inch or more backwards and forwards, so as to put the posterior pillar of the fauces on the stretch, which is then snipped across with a long curved scissors, about half an inch behind the tonsil, by which cut the principal part of the palato-pharyngeus will be divided; then, if it seems desirable, the anterior pillar of the fauces is touched with the scissors, so as to make the section of the palato-glossus —a proceeding which I scarcely deem requisite. In some instances it seems difficult to arrest all muscular movements by these incisions, and I am inclined to attribute this to the action of that end of the palato-pharyngeus, which is attached in front to the bone of the palate, as also to vermicular motion in the muscles after division; but, even though this be the case, the soft flap on each side is much more under the surgeon's command than if no such preliminary wounds were made; the needles can be introduced more readily, and the margins of the gap can be brought together with greater facility, while there is infinitely less drag upon the stitches when they are secured. When the operation is done without these incisions, there is trouble in keeping the first noose of the ligature tight until the next is cast. This is less likely to happen if the course that I advise be pursued. If care be taken, in dividing the levator palati, not to run the knife towards the upper and back part of the pharynx, there is no harm to be dreaded from the incision above described. Were the instrument carried far upwards and backwards, the internal carotid would be in danger; but if its point be pushed straight outwards and forwards, it will sink into the pterygoid fossa, and possibly divide the tensor palati muscle, when it can come in contact with the external pterygoid process only. Division of the tensor palati does not seem to be required, as that muscle has a very feeble influence over the movements of the velum."

It is a great mistake to put in too many threads, as the very object we seek to attain, namely, union throughout the entire, is thus frustrated, owing to the injury inflicted upon the delicate, soft structures: for the same reason should we most carefully guard against too great tension of the ligatures.

For the introduction of the plan of operation in which the soft palate is stripped from the bony vault, we are indebted to Dr. Mason Warren, of Boston. This is a most admirable method of filling in cavities in the hard palate, and, inasmuch as it is nature's curtain, it answers all purposes better than any obturators which may be artifically supplied.

The next was a patient of robust health, and a little beyond the middle age, who had for some time been suffering from all the symptoms of stone in the bladder, and who had presented himself a few weeks since as an in patient. He had been very carefully examined upon two occasions, but no stone could be detected; on a third examination, however, it was discovered that a stone did exist in the bladder, and he was accordingly admitted into the hospital, and placed upon the usual preliminary treatment.

Having been allowed to retain his urine for a few hours before the time appointed for the operation, Mr. Fergusson, previous to introducing the lithotrite, satisfied his own mind that the stone did actually exist. The stone was ascertained to be of not a large size, and therefore a small instrument was used for its removal. It was very soon crushed, grasped in the lithotrite, and without any difficulty, being still between the blades of the instrument, was drawn out as far as the narrowing at the orifice of the urethra; here the instrument was removed, and the fragment of the stone was left in the urethra. Mr. Fergusson then, by merely pressing his finger and thumb upon that part of the penis which retained the broken calculus, expelled it from its seat of lodgment. There was very little hæmorrhage. The stone, somewhat the shape of a filbert, and of about half the size of the kernel of the same, had been seized in its long diameter, and had opposed very little difficulty to removal; it was found to be only a fragment, and probably one half; acting on which supposition the lithotrite was again introduced, and the rest of the calculus was ascertained to be occluding the urethra at about its membranous portion. Extraction by the scoop, or by the lithotrite, being impracticable, Mr. Fergusson pushed the stone back into the bladder, and then endeavoured to seize it; but as this was not possible, the legs and hips of the patient were somewhat elevated so as to throw the stone more backwards in the bladder, and a few ounces of water were injected, in order to compensate for that quantity of urine which was necessarily lost while the patient was under examination. The crushing instrument was again passed, but as the stone could not be detected with facility, Mr. Fergusson preferred to postpone any further explorations.

He then demonstrated the difficulty in eliciting sound from a lithotrite so small as that used by him on the present occasion, especially when struck against a small fragment of calculus; another impediment to the eliciting and travelling of sound in cases similar to the present is that the urine, after the needful manipulation, becomes commingled with blood, and that a clot may perhaps surround the stone. Under these circumstances it will also be difficult to detect the stone by the sense of touch.

Mr. Fergusson prefers that the patient should retain his urine for a few hours than that there should be any water injected. In the case now under consideration there was a very great immunity from pain while the operation was being performed, and the man seemed scarcely at all to feel the presence of the instruments. There was likewise very little pain inflicted by the withdrawal of the calculus, per urethram, by means of the small lithotrite. We know that many are strongly opposed to this plan of treating the fragments of a crushed calculus, but in the hands of Mr. Fergusson it seems to be eminently successful, and not to be attended with those bad consequences, on account of which it is deprecated. The objections to the performance of lithotrity in the young male subject are:—First, the small size of the urethra, so that the instrument used for crushing must, of necessity, be very small, and the fragments, unless indeed they be very minute, cannot pass away; secondly, the bladder and entire urethra are very much more sensitive than in the adult.

The contraindications to the operation, even in the adult, are:—First, a very narrow urethra, whether such a narrowing arise from a defect in development or from organic disease occuring in a urethra naturally well formed, or from any tumours of so large a size as almost to produce occlusion of the canal. Such a tumour may be formed by the

prostate, and then there may present "impediments which the utmost skill may not be able to surmount." Thirdly, a sacculated bladder, because each sac may, when the stone is broken, become a resting place for a fragment, and each fragment may possibly have become a nucleus for a larger calcareous development; fourthly, and perhaps the most important contraindication, is great irritability of the urinary apparatus, that is, of the urethra and bladder. We have seen cases in which the urethra was intolerant of the contact of any instrument, and that, too, used in the gentlest possible manner, and by experienced hands; again, we have witnessed the bladder in such a highly sensitive condition that, as soon as the instrument entered it, its muscular coat was thrown into strong spasmodic action, and the urine was forcibly expelled along the side of the lithotrite, a powerful and irresistible desire to empty the bladder having been created.

This excitability, in some instances carried to so high a degree as to border on acute inflammation, may be relieved, if not altogether overcome, by the very passing of the instruments necessary for the detection of the stone and for its crushing; on the other hand, we may have cases under our care in which there has been, comparatively speaking, no irritability until we began the sounding, &c., but in which an irritability is induced of such a nature as to preclude the possibility of operating at the time.

There was no chloroform used with the patient, nor, we believe, is it the custom of Mr. Fergusson to employ it in cases of a nature similar to the present.

In the course of his remarks, Mr. Fergusson mentioned that, when there was no abnormal condition of the urethra as regards its size, when, in fact, the calibre of it was not diminished, but preserved its natural width, there was always some little resistance offered to the removal of the stone by the natural narrowing of the passage at about that point where it passes through the triangular ligament, or to define it more accurately, at the front part of the membranous portion of the urethra.

The third case was that of a strong, robust, young woman, the lower end of whose radius was affected with necrosis, and for the removal of which Mr. Henry Smith had, upon a previous occasion, cut down upon the diseased bone, and taken it away; as, however, some other portions were, on a subsequent examination, found to be diseased, he extended the line of his former incision upwards, and by means of the cutting pliers, took away some not very small pieces of necrosed bone. This done, he then gouged and scraped away any other portions of the radius which were implicated.

The wound being stuffed with lint, the arm was swathed in a bandage, and the patient removed.

UNIVERSITIES OF SCOTLAND.—A movement is at present on foot in the Scotch Universities to reduce the Lectures on Midwifery and Materia Medica to three months' courses, and to transfer these classes from the winter to the summer session. This improvement, in which the English schools some time ago set the example, has, we understand, the support of the Universities of Glasgow and Aberdeen, but is opposed in the University of Edinburgh.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—This society, founded in 1788, and now giving, in half-yearly and other relief, about 2,000*l.* a year, has within the past week received a Royal Charter of Incorporation, and is become the Society for the Relief of Widows and Orphans of Medical Men, the name having been shortened a little. The anniversary dinner is on the 28th of May next, at the Albion Tavern, Aldersgate street: the President, T. A. Stone, Esq., in the chair.

THE HEALTH OF THE PRUSSIAN ARMY is said to have suffered much from the severity of the weather during the campaign. There are ten per cent. of sick, chiefly from maladies of no dangerous character Typhus fever has, however, appeared, though not in an epidemic form. There are numerous hospitals for the service of the army, many of them in retired rural situations. The sick, when too numerous for the Schleswig hospitals, are sent to Hamburg.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XI.

ADEPS PRÆPARATUS.—It is, of course, of the utmost importance in the preparation of ointments to have good sweet lard, which will keep for a considerable time without becoming rancid. For this purpose it is usual to submit the lard to some process which shall remove from it everything likely to promote decomposition. There is, however, some difference of opinion among Pharmaceutists as to the best mode of treatment to be adopted. Mr. Hills, in a paper to the Pharmaceutical Society some time back, recommended that the membranes should be removed mechanically from the flare, and then the lard kneaded, and washed in a current of water to remove everything soluble. Mr. Squire, on the contrary, objects to washing the lard, but having melted it and removed the membrane by careful straining, applies heat until all the water it contains is expelled. The London Pharmacopœia gave no directions for preparing lard, but the British Pharmacopœia gives a process for preparing it, which is in accordance with the method of Mr. Squire. Whatever plan is adopted, no doubt the most essential point is to remove all trace of membrane. It is also an advantage to free the lard entirely from water, which certainly assists in setting up rancidity.

ÆTHER.—A process is given in the British Pharmacopœia for the preparation of ether. In this, as in many other cases, it would, we think, have been more judicious to have simply given a description of the substance, and omitted the process. Pharmaceutists are hardly likely to prepare for themselves the ether they consume; but even if they wished to do so, they would find the method described in every chemical manual. The process of the Pharmacopœia is the continuous process, which is always employed by the manufacturer. It is described as follows: Mix ten ounces of sulphuric acid and twelve ounces of spirit in a quart glass matrass; connect the flask with a condenser, and distil with a heat sufficient to maintain the liquid in brisk ebullition. As soon as the etherial fluid begins to pass over, supply fresh spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal the volume of the liquid which distils over. When the whole of the spirit (38 oz.) has been added, and forty-two fluid ounces have distilled over, the process may be stopped. These are the Pharmacopœia directions; they are not, as will be presently seen, quite perfect.

When spirit and oil of vitriol are mixed together, and the mixture is raised to the boiling point, combination between the elements of the alcohol and the sulphuric acid

takes place, and a new body is formed, which chemists have named *sulphovinic acid.* Sufficient elevation of temperature for this purpose is generally produced by the simple admixture of the two substances. The change which occurs may be thus represented :—

$$C_4 H_6 O_2 + 2 (H O, S O_3) = (H O, C_4 H_5 O, 2 S O_3) + 2 H O.$$
Alcohol. Sulphovinic acid.

Sulphovinic acid, although it contains the elements of sulphuric acid, manifests none of the characters of that substance; it combines with bases, and forms salts with lime and baryta, which are freely soluble in water. The first step in the preparation of ether, then, is to produce sulphovinic acid. The second step is to decompose this body by the action of heat. But the nature of the decomposition which occurs depends upon the temperature employed. When the sulphovinic acid, that is to say, the mixture of spirit and oil of vitriol, is maintained at 260 deg., or below, it is resolved into sulphuric acid and alcohol, which volatilises, and contains only minute traces of ether. When the temperature ranges between 280 deg. F. and 310 deg., then the acid breaks up into sulphuric acid and ether, and only a minute quantity of alcohol is liberated. If the temperature reaches 320 deg. or above, then no ether is formed, but olefiant gas, oil of wine, and other products take its place. The ether-producing temperature, therefore, is confined within a limit of 30 degrees. In the continuous process, a rise of temperature from the accumulation of liberated sulphuric acid in the distillatory vessel is prevented by the introduction of fresh spirit. Sulphovinic acid is thus being constantly formed and decomposed; the same amount of sulphuric acid converting an almost indefinite quantity of alcohol into ether and water. But to conduct the operation successfully it is essential that the supply of fresh spirit shall be so regulated that the mixture shall boil actively, while it maintains a constant temperature of 300°, or as near that temperature as possible. To effect this it is necessary to keep a thermometer in the retort, and to make its indications the guide for the addition of the spirit. The Pharmacopœia, however, makes no mention of temperature. It simply directs that the spirit shall be added in such quantity as to equal the volume of the fluid which distils over. This would be very difficult to judge of, especially in working with small quantities of material.

The crude ether so obtained is purified by agitating it with a solution of chloride of calcium and a little slaked lime, then separating it, and submitting it to re-distillation.

In the Materia Medica, ether is described as "oxide of ethyl with about 8 per cent. by volume of alcohol." Why the ether used in medicine should necessarily contain 8 per cent. of alcohol, we do not know. Pure ether may be readily obtained, and has been hitherto used, in accordance with the previous Pharmacopœias.

The tests given are as follows:—"Sp. gr. 0·735·50 measures agitated with an equal volume of water, are reduced to 41 by an absorption of 18 per cent. It evaporates without residue." Pure ether only dissolves to the extent of 10 per cent. in water; the proportion which dissolves in excess of this amount represents the alcohol which the ether contains. No means are given in the Pharmocopeia for recognising ether which has beeen made from methylated spirit. Such ether is in constant use, but it is never pure. It may be readily detected by putting a few drops on a piece of filtering paper, and then allowing it to evaporate. By smelling the paper at the instant when the ether has gone, the odour of the wood spirit may be readily detected.

The Pharmacopœia represents ether by the formula $C_4 H_5 O$. But chemists are now generally agreed that this formula should be doubled. This is done, not merely in accordance with theoretical considerations regarding the equivalent of oxygen, but also because the vapour density of ether indicates the numbers $C_8 H_{10} O_2$, and because the researches of Professor Williamson on the double ethers also point in the same direction.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

MARCH 2nd, 1864.

DR. OLDHAM, PRESIDENT, in the Chair.

The following gentlemen were elected Fellows of the Society: F. J. Butler, M.D., Winchester; Thos. Chambers, L.R.C.P, London; Ed. Fussel, M.B., Brighton; Samuel N. Harrison, Patrington, Hull; Ed. Jackson, M.B., Sheffield; W. N. Price, Esq., Leeds; A. G. P. Wilks, M.D. Cantab., Guy's Hospital.

Dr. HICKS read a report on two cases of monstrosity exhibited by himself and Dr. Gervis at a former meeting of the Society.

CASE OF FATAL UMBILICAL HÆMORRHAGE IN AN INFANT.

Dr. GRAILY HEWITT related the particulars of a case of hæmorrhage from the umbilicus. The mother of the patient, a weak, ill-nourished individual, was delivered of a female child at about the eighth month, in the British Lying-in Hospital. She had previously lost a child, a few days old, from bleeding at the mouth, ears, and rectum. At birth, the infant was weakly, and the circulation languid; moreover, in the course of a few hours, the child became jaundiced. The second day after birth a very slight appearance of blood was noticed at the insertion of the cord. On the third day hæmorrhage set in, and when seen by Dr. Graily Hewitt had lasted for upwards of an hour. The child was then excessively pale, and moribund. Further loss of blood was prevented by application of a ligature *en masse*, but the infant died about an hour afterwards. The blood exuded as from a sponge at the junction between the cord and the abdominal wall. Post-mortem examination showed great congestion of the liver, and slight hæmorrhagic effusion into the peritoneal cavity. There was no ulceration of the stump of the cord inwards through the abdominal wall.

Dr. Graily Hewitt alluded to a series of cases of this affection published by Grandidier. In a large portion of them jaundice was observed, as in the above case; and in a few the existence of a hæmorrhagic diathesis was well marked. The treatment carried out in the above case had been found most successful in the hands of others—namely, the use of the ligature *en masse*. The mortality from this affection had been found to be very high—namely, 83½ per cent.

Dr. TYLER SMITH presented the notes of

EIGHT ADDITIONAL CASES OF OVARIOTOMY.

The notes of twelve cases have already been presented to the Society.

CASE 13. *Multilocular tumour of the right ovary; operation; recovery.*—E. H——, aged thirty-three, unmarried. Abdomen

forty-two inches; growth rapid. Operation, June 16th, 1862. Incision, four inches. Tumour composed of two principal cysts, full of purulent matter. Cysts tapped first. Pedicle secured by silk, divided, and allowed to drop into the pelvis. Tympanitis and sickness severe on third day; relieved by calomel, turpentine, &c.; iced water and milk. In October following quite well.

CASE 14. *Multilocular tumour of right ovary; ovariotomy; recovery.*—Mrs.. B.——, aged fifty-four. Weak and emaciated; size great. Has lived in West Indies. Operation October 13th, 1862, under chloroform. Extensive adhesions on right side. Numerous cysts with gelatinous contents. Large incision. Pedicle allowed to drop into pelvis. Wound healed by first intention. Convalescence tedious. Large doses of opium, to which she had been accustomed, necessary. Now in better health than she had been for years.

CASE 15. *Multilocular tumour of left ovary; operation; recovery.*—E. B.——, aged thirty-two. Much emaciated. Measured forty-two inches round. Pedicle returned into pelvis after operation performed in usual way, under chloroform. At night, enema with laudanum, the only medicine given. Took stimulants early. Excellent recovery in less than a month.

Case of ascites with malignant tumour, supposed to be ovarian; operation; death.—Patient, forty-three years of age, had had thirteen children, youngest fifteen months old. Had gradually increased in size since birth of child. Measured forty-eight inches round. No unusual pain. Pulse good; not much emaciated; complexion not like that seen in malignant disease; considerable œdema of abdominal walls. A tumour, believed to be ovarian, felt through ascitic fluid on left side. Incision being made, a tumour was found firmly adherent to abdominal walls. It was removed, at also the ascitic fluid. Other tumours of malignant character then found connected with intestines and other structures. Patient never rallied. Death four hours afterwards. Numerous cancerous tumours found in omentum, &c. Ovaries diseased, but small.

CASE. 16. *Multilocular tumour of left ovary; operation; recovery from operation; death three weeks after from bronchitis.*—General health bad; subject to bronchitis. Operation, April 15th, 1863. Strong adhesions on left side. Pedicle returned into pelvis. At end of fortnight sat up daily. She was removed on May 5th, at her own request, to the hospital. She ate a good breakfast on May 6th, but died, almost suddenly, late on the same day. Extensive emphysema of both lungs, and thickening of bronchial tubes. Pedicle and ligature enclosed in a sac formed by coagulable lymph.

CASE 17. *Multilocular cyst of left ovary; operation; recovery.*—Mrs. B——, aged forty-three. Enlargement of the abdomen noticed for six years. Operation, June 26th. Tumour, one large cyst, with gelatinous contents. Adhesions considerable. Pedicle treated as in the foregoing cases. Left for the country on July 30th.

CASE 18. *Multilocular cyst of left ovary; operation; recovery.*—Tumour growing for eighteen months; measurement forty-six inches. Tumour very adherent. To a small vessel of intestine wounded in separating the adhesions a metallic ligature was applied. Pedicle treated as above. No bad symptoms.

CASE 19. *Multilocular colloid tumour of the left ovary; operation; death on the sixth day.*—Miss S——, aged fifty-eight. Tumour growing a year. Tapped a month previously. Tapping now again necessary; and a fortnight afterwards, having again filled, ovariotomy was decided on. Many adhesions. Tumour made up of large masses of colloid. Pedicle very small. Some hæmorrhage from tearing the pedicle, and it was secured with great difficulty. The patient rallied after becoming very exhausted, and took food well. On the fifth day bad symptoms set in; and death occurred on the following day.

CASE 20. *Multilocular tumour of the left ovary; operation; recovery.*—Miss M——, aged thirty-nine. Tumour growing two years. Much emaciated from bronchitis. Perfect recovery from the operation, which was performed in the usual way. Is now in excellent health.

The author remarked, that of the twenty cases sixteen had recovered, or 80 per cent.; that is, excluding Case 16, in which death occurred from bronchitis three weeks after operation; including this case, the cures were 75 per cent. He had now returned the pedicle into the pelvis in ten cases and with most satisfactory results. In all the poor women operated upon, the disease incapacitated them from work; in the others, the operation could not have been delayed without risk to life.

The PRESIDENT considered that in cases of doubtful diagnosis the operation of tapping was advisable, as preliminary to the other operation.

Dr. TYLER SMITH thought that in the case alluded to by the President no positive information would have been obtained by tapping. The diagnosis was extremely difficult in some cases. In the particular instance in question there was extreme œdema of the abdominal walls, and he thought it probable that such œdema might be found in other cases to be associated, as it was in this case, with malignant disease. In answer to a question from Mr. Cumberbatch, Dr. Tyler Smith stated that he preferred non-metallic ligatures for securing the pedicle.

Mr. SPENCER WELLS said that the question raised by Dr. Tyler Smith as to the mode of securing the pedicle was one of the most important which could be considered by the Society. He had followed Dr. Tyler Smith's practice in five cases. From the first no conclusion could be drawn, as the patient would probably have died had the pedicle been secured in any other manner. Two of the other four had recovered more quickly than they probably could have done under any other proceeding, although in both there was more evidence of sthenic peritonitis than was often seen where the clamp was used. In two other cases the patients died of diffuse peritonitis, and he (Mr. Wells), thought they might have done better if the clamp had been used. In one no post-mortem could be made. In the other, the ligature and the tissue it enclosed were surrounded by a sort of capsule, formed by two coils of small intestine adhering together and to the pedicle by recent lymph. It was a matter of some doubt whether such a condition might lead eventually to intestinal obstruction, and be more objectionable than the adhesion to the abdominal wall which followed the clamp. His (Mr. Wells's) own impression of the three modes of dealing with the pedicle was, that when the pedicle was long, the clamp was the safest and best mode; but that when the pendicle was short, it was better to cut off the ligatures short, and return the tied pedicle, than to leave the ends of the ligature hanging out through the abdominal wall. In reference to the question of the diagnosis of cancer, he had never met with a case of cancer in the abdomen which had not been diagnosed without operation. The diagnosis of cancer of the peritoneum was not difficult. In one case cancer of the right kidney was easily recognised, and was found after death to weigh 17lbs. In two other cases of cancer of the ovary—one of the left ovary and one of both ovaries, with large quantity of ascitic fluid—the diagnosis was easily made out after the preliminary tapping suggested by the President, and was proved to be correct after the death of the patient. In neither of these cases was there much œdema of the abdominal wall, and he (Mr. Wells) differed completely from Dr. Tyler Smith in his opinion that this œdema could assist us in making out whether an abdominal tumour was innocent or malignant.

Dr. GRAILY HEWITT mentioned a case in which he had observed very extensive œdema of the abdominal parietes, together with great œdema of the lower extremities, and in which the abdominal tumour present, and which reached above the umbilicus, was constituted by the urinary bladder enormously distended with urine, It was evident, therefore, that œdema of the abdominal walls could not be depended on as a sign of malignant disease.

Dr. J. BRAXTON HICKS wished to ask Dr. Tyler Smith whether he had found any subsequent untoward result from the dropping in of the ligature. Although this practice had been shown by the results to be apparently unattended with

danger, and possessed many advantages, still the ligature had possibly to be accounted for at some future day. He considered the perfection of ovariotomy would be nearly gained by doing without any ligature at all. He believed it would be possible, by firmly compressing the pedicle for an inch or so by a serrated clamp, or some such apparatus, to condense the tissues so firmly as to completely prevent bleeding. The pedicle could then be dropped into the pelvis. He threw out this suggestion, because he had found in examining tissues after the use of the écraseur that it was nearly impossible to unravel them; and he thought if the width of the compressor were increased, no bleeding would result.

In reply, Dr. TYLER SMITH stated that he had every reason to be satisfied with the results of the plan of dropping the pedicle into the pelvis after securing it by ligature, and he could with confidence recommend it as being probably safer, and certainly more convenient, than the other plan. He should be very glad to have an instrument such as that suggested by Dr. Hicks for dividing the pedicle, if it could be relied on for preventing hæmorrhage.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 15.

Mr. PRESCOTT HEWETT, President.

(Continued from page 254.)

Dr. BARKER brought forward a specimen of

HYPERTROPHY OF THE HEART.

The left ventricle was the one chiefly enlarged, and Dr. Wale Hicks had found that many of its fibres had undergone fatty degeneration. The heart weighed twenty-five ounces; he brought the specimen, not on account of the extent of the disease, but on account of the peculiarity that the patient had had no symptom of heart disease until five weeks before his death, and after admission there were no very positive symptoms. There were no sounds, the apex could not be felt, and there was no pulse. There was no obstruction, and the kidneys were healthy.

Mr. ERNEST HART exhibited a specimen of

DEPRESSED FRACTURE OF THE SKULL FROM A PATIENT WHO HAD HAD NO HEAD SYMPTOMS.

It was removed from the body of a patient who was thrown from a coach twenty-one years ago. The outer table of the parietal bone was fractured, and driven inwards in the centre of the fracture. The internal table was not broken to nearly the same extent, but was fractured in the centre. Repair had taken place to a very considerable extent, and as there had been no motion there was no callus. The history gathered from the Surgeon who attended the patient at the time of the accident was to the effect that the symptoms had been very slight. He was insensible for half-an-hour. Then he slowly recovered, and had no further symptoms. Mr. Hart added that there were two similar specimens in the museum at Fort Pitt.

The PRESIDENT said there was one also in the museum of the College of Surgeons.

Mr. TEEVAN remarked that he had made a number of experiments which all clearly showed that when a foreign body passed completely through one side of the skull the aperture of exit was always larger than the aperture of entry, and this too, whether the force passed from within or from without. Mr. Hart's specimen seemed apparently to contradict this proposition, inasmuch as the line marking the boundary of the fracture in the external table was much more extensive than the corresponding line marking the fracture in the internal table. But it must he remembered that in this case the head merely struck the ground, and that consequently the latter had only driven inwards a portion of the skull, and had not itself passed into the interior. The case, therefore, was entirely different from that of the passage of a foreign body into the head.

Dr. CRISP exhibited

MICROSCOPICAL PREPARATIONS OF THE OXYURIS VERMICULARIS IN MEN,

for the purpose of showing the extraordinary number of eggs in this entozoon, and more especially to call the attention of the Society to the mode of expulsion of the ova of the worm, which he believed he was the first to notice. When the female worms are expelled from the body, a white spot is seen with the naked eye, about a third the length of the body from the head. On placing the worm under the microscope, this white spot is found to be composed of a pile of eggs, which are expelled by an artery-like contraction of the oviduct. This process of expulsion is often continued for three or four hours, when the oviduct is nearly emptied. Assuming that the ova in each worm amount to 5,000, the number in some persons would reach to a million or more.

Dr. CRISP also exibited specimens of the

STRONGYLUS FALARIA IN THE LUNGS OF THE LAMB AND THE CALF,

with a wax cast of the lungs of the former, for the purpose of showing the immense number of these parasites, which block up the air-tubes, and in this way occasion the death of a great many lambs and calves in this country. Dr. Crisp said that in a few instances he had observed the same process of expulsion of the ova in the strongylus falaria as in the oxyuris, in a few instances; but there was this curious difference between the eggs of the two worms, that whilst in the former the young were generally matured, in the latter no appearance of an embryo was visible.

Dr. GIBB exhibited a drawing of

ACUTE EPIGLOTTIDITIS,

occurring under his care in January last, in a gentleman, aged thirty-one, who had phthisical disease. The voice had been gradually going for ten days, and two days before he was seen by Dr. Gibb, dysphagia, with fluids, set in. The laryngoscope revealed the epiglottis enormously swollen, projecting upwards and backwards in the form of a bright crimson red tumour, like an immense plum. It was immovable unless in the movements of the tongue, and could be seen readily at the back of the mouth without even introducing the laryngeal mirror. The larynx was clear, and free from disease, the inflammation and swelling being confined to the epiglottis. Under treatment, local and constitutional, the more urgent symptoms had subsided in five days, and a good recovery ensued.

A LADY MILITARY DOCTOR.—Miss Mary C. Walker, M.D., arrived here last week, with orders to report to Dr. Perrin for duty. She has been appointed to Colonel McCook's brigade, and has just left for Gordon's Mills. The young lady is said to thoroughly understand her profession, and is very pretty.—'Chattanooga Gazette.'

OVERCROWDING AT LEICESTER.—From the Report of Dr. John Moore, the Medical Officer of the Board of Health, it appears that during the last twelve months there had been 529 more deaths than in the preceding year. This is attributable, not to any want of proper cleanliness, drainage, &c., for that is said to have been well regulated, but to the overcrowded state of the dwellings and factories, over which the Board have no control.

DEATH FROM LOCKJAW.—A few days since, as the convicts at Carlisle Fort were out for recreation, one of them, an able-bodied man, in attempting to vault or leap over the top of an iron chimney protruding on the platform they were on, missed his distance, alighting on the edge of the iron with the weight of his body, injuring his thumb, the first joint of which was severed, and although immediately attended to by Dr. Travers, he died after three days from lockjaw.—'Cork Reporter.'

THE LATE SIR HUMPHRY DAVY.—A committee has been organized at Penzance, with the object of raising a monument to the memory of the celebrated chemist, Sir Humphry Davy. At a meeting recently held, it was announced that two ladies were willing to subscribe 1,000*l.* each, provided the monument take the form of almshouses. The liberal offer was accepted, and numerous other subscriptions have been received in furtherance of the object.

THE MEDICAL CIRCULAR.

WEDNESDAY, APRIL 20, 1864.

ON MODERN CHANGES IN THERAPEUTICS.

It is clearly the duty of the conductors of the Medical periodicals to point out to their readers not only the changes which have occurred from time to time in the treatment of disease, but also the reasons why those changes have been made. The tyro in medicine, who endeavours, on the one hand, to make himself acquainted with therapeutics by reading the most esteemed works, and on the other to follow out his reading by observation at the hospitals or on private patients, will find an almost irreconcileable discrepancy between theory and practice, between the doctrines inculcated by authors and the actual treatment of maladies at the bedside. These considerations have induced us to examine the question in a practical point of view, and to inquire why the teaching of books and the actual management of disease are in such apparent antagonism to one another.

We can hardly take up a manual of medicine or surgery or even a treatise on any special disease or injury, without finding therapeutical doctrines advanced which are at variance with the practice seen to be pursued at our hospitals or among private patients, and especially is this the case with the books emanating from the seniors in our Profession. Do we inquire the treatment of inflammation in general, we find the almost stereotyped answer that we must bleed, purge, give calomel and antimony, and enjoin strict antiphlogistic diet; do we ask the treatment of cerebritis, pleuritis, pericarditis, peritonitis, we receive the same reply, with the further generalisation that diseases ending in *itis* all require the treatment we have just alluded to. But if we adjourn to any of our hospitals, and watch the practice of the physicians and surgeons, we shall find that the lancet, or, indeed, the abstraction of blood in any way, is but rarely resorted to, even in those very cases where it was once supposed imperatively necessary, and that the other depletory measures have almost alike fallen into desuetude. In some quarters, indeed, the revulsion from the former practice has been so strongly marked that, instead of the belief that inflammation is a condition requiring depletion by low diet and mild diluents, a notion has sprung up that inflammatory diseases ought to be uniformly treated (apparently on the principle of *similia similibus*) by the unsparing use of stimulants.

Again, let us carry ourselves back, in imagination, into the wards of the London Fever Hospital in its close and insalubrious site at Battlebridge, thirty or forty years ago, and witness the copious abstraction of blood which was then universally practised upon the patients, and which was taught to be as necessary to subdue the complaint as the use of the fire engine is essential to stop the conflagration of a building. Then, by way of contrast, let us repair to the present hospital for the same disease in its new and airy site, with its ample and well-ventilated wards, and we shall find that the abstraction of blood is scarcely ever contemplated as a remedial agent, that hardly a leech is ever employed, that depletion of all kinds is avoided, and that the patients are allowed wine and nourishment almost from the commencement of their malady.

There are two modes of accounting for this extraordinary difference of practice as pursued by our predecessors and by ourselves. One is that we are wiser than our forefathers, and that we avoid the errors into which they fell; and the other is that it is not we who have changed the principles of our treatment, but that disease has changed its type and character. There is probably something to be said on both sides of the question, and the exclusive advocates of either theory may both be in the wrong.

It cannot be denied that the science of Medicine and Surgery, or rather Pathology, has greatly extended of late years, both at home and abroad; and the application of chemistry and the revelations of the microscope have been of infinite service in teaching us the real nature of disease, and in showing us that the modes and varieties of morbid action are far more numerous than superficial observers may imagine. In former times it was enough to recognise certain diseases as inflammatory, and others nervous, and others cachectic, but now, by the investigation of minute objects and by chemical tests, the presence of parasitic animalcules and plants is found to be a frequent cause of disease, or we find molecular degenerations of various kinds sapping the vitality of the internal structures, or chemical elements, deficient or excessive, or alien to the system, polluting the stream of life. To imagine that blood-letting can be of any service in such cases, or that a mere routine treatment of scouring out the bowels by blue-pills and the black draught can be of any essential advantage, would indeed be the dream of the quack, and we may congratulate ourselves on our superior information, as compared with that enjoyed by the medical practitioners of a bye-gone epoch.

But shall we assert, on the other hand, that diseases are really always the same at every period of the history of the world, and that they therefore always require identically the same treatment, and that ignorance, or rather imperfect knowledge, is the only reason to be assigned for the therapeutical practices of our ancestors? Without answering these questions in a dogmatic manner, it is better, perhaps, to put forward some considerations of a general nature, on a subject, which, from its very nature, is incapable of accurate demonstration.

It is quite certain that several diseases, which formerly prevailed to a very great extent in our own country, have entirely disappeared, as, for instance, the plague and the sweating sickness, and it is no answer to assert that their disappearance has been due to the superiority of our hygienic measures as compared to those existing three or four hundred years ago. We merely state that they have disappeared, no matter what the cause may have been. Other diseases again, which formerly prevailed with very great severity, and carried off large numbers of the population, have become very considerably modified in their character,

and are far less fatal than at former periods. Such are ague and small-pox, and here again it is no answer to attribute the mitigation of the severity of these diseases to the discovery of cinchona or quinine, or to the practice of vaccination. All we allege is, that these two diseases are not nearly so fatal as they formerly were. Coming to still later periods, most middle-aged practitioners can recollect that gout was a very common disease among the upper and upper-middle classes of society, and that the disease has become comparatively infrequent as the use of wine has become more moderate. All these circumstances show, we think, that diseases really change their aspect at different periods, and our discovery of causes to account for the change does not in any way alter the facts.

Now, on the other hand, have no new diseases made their appearance among us, and have no old ones become more frequent or assumed more serious characters? It is of course, in very many cases, extremely difficult to answer this question, because the ambiguous or imperfect manner in which many diseases are described by ancient authors leave great room for doubt, and afford latitude for opposite discussion. Whether Bright's disease of the kidney, or Addison's disease of the supra-renal capsules, or leucocythemia, or fatty degeneration of the heart, are really more prevalent than they formerly were, or whether they were merely overlooked by old writers, it is quite impossible to determine; but surely no one who happened to be in practice before the year 1830, can doubt that epidemic cholera was a new disease in England in the present century, or that influenza assumed a more severe form and more epidemic character soon after the outbreak of cholera. Let it even be admitted (though we think the point exceedingly doubtful) that spasmodic cholera has really raged in former periods in this country, and that influenza has prostrated whole communities on previous occasions as it did in 1833, yet the fact still remains that diseases do not, year by year, assume the same form, but that they come and disappear in periods, or cycles, or waves, like the appearances of some erratic comet within the limits of the solar system. The presence of diphtheria may also be cited as an instance of a disease, which, whether new or not in England, was certainly considered as a stranger by the whole of the Profession in this country, and by many indeed was regarded as a myth, until its extensive ravages left no doubt of its real nature, or of its fatality. Diphtheria may indeed have been described by Aretæus, as is urged by Bretonneau, or as the same French authority learnedly maintains, it may have prevailed in Italy and Spain in the seventeenth century, but did it exist in France before 1818, or in England before 1850? If all these diseases have constantly and uniformly prevailed among us, then of course the type of disease and the diseases themselves have always been the same, and the theory of the change of type is a brain-sick fallacy; but we apprehend that there are few Medical practitioners who have exercised their reasoning faculties or their powers of observation, who will deny that from time to time they witness the advent of diseases with which they were previously unacquainted, or that they are compelled to modify their plans of treatment according to the varying aspects that a given malady may assume.

SUMMARY OF THE WEEK.

GARIBALDI.

It is now ascertained that the wound in Garibaldi's foot has entirely healed, and the skin presents only a scar. There is, however, considerable stiffness of the ankle, probably due to anchylosis of the joint. Garibaldi has been attended by Mr. Fergusson since his arrival in this country, and also by Mr. Partridge, who visited him by appointment last Thursday, and who states that Garibaldi's visit is in no way connected with the necessity of seeking for medical or surgical advice or treatment.

THE 'BRITISH MEDICAL JOURNAL' AND THE MEDICAL COUNCIL.

Without expecting that the Editor of a Medical Journal should be omniscient or infallible, we think that he ought to have sufficient knowledge of current topics to prevent the writers under his control from issuing to the world statements which are positively erroneous, or which are calculated, or perhaps intended, to mislead the readers. In the last number of the 'British Medical Journal,' some writer, very ignorant of his subject, has been permitted to lecture the Medical Council on its duties in a strain which is almost unsurpassed for its arrogance and its wilful exaggeration. It is asserted, in the first place, that the College of Surgeons and the Society of Apothecaries differ in opinion with the Medical Council as to the recommendations relating to Professional study issued by the latter body, and that they (the College of Surgeons and Society of Apothecaries) "offer a continual opposition to the carrying into effect of the recommendations which a majority of the Medical Council has deliberately approved. This opposition," the writer goes on to say, "is the more painful, when contrasted with the readiness with which other corporations have brought their regulations into the strictest conformity with the recommendations of the Council." Now, we have received and perused the whole of the minutes of the meetings of the Medical Council, and we have failed to ascertain that the Society of Apothecaries has ever placed itself in opposition to the Medical Council on the subject of Medical education, whatever the College of Surgeons may have done. So much for positive mis-statement, and now for wilful exaggeration. We have affirmed, on the strongest and best evidence, that the students, of the London Schools of Medicine at least, were neither compelled nor expected to attend a large number of lectures, and the writer in the 'British Medical Journal' now publishes the following preposterous list of subjects, which he says are actually taught in the London Schools, and which, he wishes it to be inferred, are enjoined by the Examining Bodies:

"We have, *imprimis*, the following courses of lectures:—Anatomy, descriptive and surgical; anatomy, physiological and general; anatomy, comparative; anatomy, histological and minute; anatomy, morbid; anatomy, pathological;

dissections; chemistry; chemistry, practical; chemistry, experimental and analytical; botany; materia medica and therapeutics; midwifery, and the diseases of women and children; midwifery, clinical; medicine; medicine, clinical; surgery; surgery, clinical; surgery, aural; surgery, dental; surgery, ophthalmic; surgery, operative.

"Then we have—demonstrations, anatomical; demonstrations, surgical operative; demonstrations of cutaneous diseases; demonstrations, microscopical; demonstrations of morbid anatomy.

"Next we come to practice, and here we find—Practice, hospital medical; practice, hospital surgical; practice, hospital, diseases of women and children; practice, hospital, out-patients' department; practice of midwifery; practice of ophthalmic surgery; practice of dental surgery, practice of aural surgery; practice of pharmacy; practice of vaccination; practice of bandaging; dressership; clinical clerkship.

"In some schools, a few extra *hors d'œuvres* are added to this intellectual feast, viz.—Palæo-zoology; natural philosophy; experimental philosophy; medical classics; public health."

All this monstrous farrago is printed *in extenso*, and with broad margins, so as to occupy a whole column in the Journal, and to make the list look the more formidable. It is needless for us to state that all these are the mere ordinary sub-divisions of our art; and if the writer had chosen to carry his imaginative powers still further, he might have swelled the list a hundredfold by printing all the subjects in sub-divisions. But surely no one in his senses will believe that any Examining Boards require attendance on all these departments as separate subjects, and we will not waste words in exposing so palpable an absurdity.

THE 'LANCET' AND THE COLLEGE OF SURGEONS.

In discussing the question of Medical Education on previous occasions, we have remarked that the whole truth in regard to the present deficiences manifested by our Medical candidates, has not, and cannot be told, owing to the natural reluctance which must exist on the part of examiners to reveal the short-comings of the pupils who come before them. The following observations in the 'Lancet' of last week, will therefore be read with interest, and we know that many of the statements are true. The facts offer a somewhat painful commentary on the working of a system which allows a single examination, and that almost on a single subject, to be a sufficient passport to practice, and the more especially if the examination is so inadequate a test of proficiency as the writer in the 'Lancet' does not hesitate to assert it to be.

"The lecturers of Middlesex Hospital told the College, a very few years since, in an able memorial, that their diploma was no test of a man's efficiency to practise. And is it now? Let the Professors of Netley, let the Examiners of the Army Medical Department, let Dr. Parkes or Mr. Paget answer. How many men who hold that diploma come before them, fresh from examination, with recent parchments and undried ink, who cannot hold a knife, bandage a limb, set a fracture, or tell a blood-disc from an air-bubble under the microscope! Their examinations disgrace the College of Surgeons. It would puzzle the most profound philosopher that ever lived to discover on what principle some men are passed and others plucked. We heard lately of a recent member of the College of Surgeons being re-examined for a post, who did not know the difference between an indolent ulcer and a cancerous sore, who could not write a prescription for a hard or soft chancre, and who proposed to prescribe two grains of elaterium as a dose. The microscope might as well be non-existent for most of the Examiners; pathology is little more than a dead letter; and it is absolutely unnecessary that any aspiring candidate for the diploma of the College of Surgeons should practically be able to take off so much as a finger. Not much, we think, is to be said for the scientific organization effected by the present Examiners."

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. FULLER contributes a Clinical Lecture on "Gout, Rheumatism, Rheumatic Gout, and Sciatica," the present subject being "Sciatica," which is illustrated by the details of some cases under treatment in St. George's Hospital. Dr. Fuller shows that the disease called Sciatica is very different in its nature in different cases, being sometimes obviously connected with a rheumatic diathesis, and in other cases being purely neuralgic. In the former instance the remedies to be prescribed are those which are known to be efficacious in the treatment of rheumatism; in the latter, quinine and sedatives, with nutritious diet, are decidedly to be preferred. In one of the cases described by Dr. Fuller, the hypodermic use of morphia was immediately attended with a favourable result, although the disease had been unrelieved by alteratives and sedatives employed in the ordinary way.——Dr. EDWARD SMITH continues his papers on "Dietary in Disease," his present subject being the treatment of "Emaciation, as connected with Asthma and Consumption." In the treatment of the former disease it is essential to supply very small quantities of food at a time, and to render the dietary highly nitrogenous; in the treatment of the latter it is necessary to increase the total quantity of food, and particularly to induce the patient to take fats in an increased quantity. New milk is the essential food for the phthisical, and not less than three pints of it should be taken daily; and as to the fats, which are generally disliked in the early stages of phthisis, their use should be insisted upon in some form or other, for although the patient may dislike one kind, the aversion never extends to all the varieties. Hence the invalid may have his choice of butter, bacon, fat boiled pork, salad oil, or cream. Alcoholic liquids are serviceable in helping to overcome emaciation, and Dr. Smith particularly recommends rum to be used with milk, or madeira, sherry, or stout to be administered daily.——Dr. J. L. W. THUDICHUM contributes a paper on "Liporocele: its Analogy to Fatty Serum of the Blood and to Chylous Urine." The case on which the paper is founded was that of a person operated upon for hydrocele by Mr. Fergusson, who withdrew a white milky fluid, which Dr. Thudichum examined, and now describes. The fluid contained a large quantity of albumen, some fatty acids, some albuminoid matter, chloride of sodium, and phosphate of soda, and its peculiarity consisted in the presence of free fatty acids in a state of most minute mechanical subdivision and suspension, aided by weak chemical affinities.

THE 'MEDICAL TIMES AND GAZETTE.'

Professor HELMHOLTZ continues his Lectures on the "Conservation of Energy." The learned Professor who, it may be recollected, is the inventor of the ophthalmoscope, devotes his present lecture to a description of the physical nature of the Sun (!) a most interesting subject, and exceedingly well handled, but certainly out of place in a Medical journal.——Dr. GEORGE HARLEY continues his Lectures on the "Urine and Diseases of the Urinary Organs," his present subject being "Urea." This substance, as is well known, consists of the same elements as cyanate of ammonia, and some chemists are disposed to regard it rather as a compound of cyanic acid and ammonia, than as a special product of the animal kingdom. The amount of urea excreted daily is liable to considerable variation. Dr. Harley thinks that urea is not the special product of any one particular tissue or organ, but the united product of all nitrogenised effete matter, and he further believes that all nitrogenised foods augment, and all non-nitrogenised foods diminish the amount eliminated by the kidneys. The drinking of water increases the elimination of urea, and common salt and coffee have the same effect.——Mr. J. L. LAURENCE continues his Lectures on the "Optical Defects of the Eye," his present subject being the nature of light and its modifications when viewed through refracting media. He describes briefly the construction and properties of double convex lenses.——Dr. LAYCOCK communicates a Case of "Obstruction of the Bowels," which terminated fatally. In this case there was enormous distension of the abdomen, which resisted all kinds of ordinary treatment, and was not relieved by galvanism. Dr. Laycock was at last induced to practice the operation of paracentesis cæci, which has been recommended by Sir Henry Cooper, of Hull. The operation afforded immediate relief by allowing the flatus to escape, but the patient died soon afterwards, and it was ascertained on post-mortem examination that there was a stricture of the first portion of the rectum immediately below the sigmoid flexure of the colon. Dr. Laycock remarks that the operation of paracentesis cæci, performed under such circumstances, affords some relief, and even if it is unsuccessful, does not render the case worse than it was before.

THE 'SOCIAL SCIENCE REVIEW.' EDITED by BENJAMIN W. RICHARDSON, M.A., M.D.—APRIL.

In this number Dr. RICHARDSON continues his interesting papers on the "Diseases of Over-worked Men," his present subject being "Mental Over-work." He describes the various kinds of literary and scientific labour, showing that each of them wears out the brain in proportion as it requires more or less of the operation of thought. Thus, the copyist or reporter, although he may work longer, does not exhaust his brain nearly so much as the original writer or thinker. Dr. Richardson expresses his approval of tobacco-smoking in soothing the brain after literary labour.——The other articles in the Journal are of a varied character, and one on "Denmark in the Past," will be found interesting, especially at the present moment.

THE 'MEDICAL MIRROR.' APRIL.

The original articles in the present number of this Journal are one by Mr. WALTER COULSON, entitled, "Remarks on Lithotrity: with Record of Fifteen Cases of Stone." The paper contains only the clinical history of the cases described, and the author reserves for another communication his comments on their history and progress.——Dr. J. C. THOROWGOOD contributes a paper on "Change of Air in the Prevention and Cure of Pulmonary Phthisis." The author recommends the bracing air of elevated districts in certain cases, and thinks that moist and damp places are generally unfavourable to the disease. The air of Devonshire is justly recommended in many instances, but, nevertheless, the disease sometimes occurs in persons who reside in that county.——Mr. J. D. EAMES communicates a paper on the "Induction of Premature Labour by the Injection of Tepid Water into the Uterus," and relates the particulars of two instances in which he successfully adopted this simple plan in the same patient. The rest of the number is occupied with miscellaneous matters, and the Reviewing Department contains a good *résumé* of the modern treatment of Syphilitic Diseases, the non-mercurial and the mercurial treatment being respectively advocated or condemned by writers on opposite sides of the question.

GENERAL CORRESPONDENCE.

FEMALE MEDICAL PRACTITIONERS.

To the Editor of the Medical Circular.

SIR,—To what gods or goddesses shall we appeal, while trying to announce the fact that the Profession lately evolved a would-be female practitioner? It was the accoucheur-skill of the venerable people living under the shadow of Apothecaries' Hall that gave us this first-born of Medical Doctresses; and it would be interesting to learn, from their own official report, all the circumstances that characterised an operation which few thought within their competency. The child, who must be extraordinarily robust to survive the ordeal to which we owe what some will call a rather equivocal blessing, may easily enough be presumed to be "going on well;" but what of the mother, unaccustomed to such a labour? We have ushered into being a very remarkable progeny, but the pangs of maternity in this case are not relieved by the celebrated sentiment of joy at the birth of a *man* child; and, if we may hazard a conjecture of the true feeling of the Profession, we must be surveying our new offspring much as some fine lady of May-fair might do, surprised at the Othello-like visage of her new-born cherub. The strangest of the phenomena that even our pursuits have for some time made us acquainted with, the portent must have an interesting meaning, if our philosophy could find it out. The *mulier formosa superné* of our poetic dreams ends in the fish-tail of a professional calling; and we must be more than human, if this prospect of a new and appalling form of rivalry does not give us quite another idea of "woman, lovely woman!"

Certain uneasy visions about lighter baskets and less occupied "Buttons" will float across the mind's eye of some; lofty views of professional standing will rise out of the dim mental horizon in disordered vistas before others; and even those who concern themselves less with such matters, will still amuse themselves with conjecturing as to who may share with the new practitioner in petticoats the precious honoraria of a first consultation, what may prove in it the interesting subject of mutual scrutiny, who shall lead in the diagnosis, and which may be the school of treatment having the honour of the young lady's preference?

The *fait accompli* of many an angry discussion and unpleasant prospect is thus at length nearly realised; and while recognising it in the accommodating spirit of modern diplomacy as the admission of a new institution into our Profession, we may be permitted to ask, how will it be in others? Are we to have the Misses Gammon and the Mesdames Quirk approaching the Law Society, and asking for admission on the roll of attornies? Is the Honourable Miss Angelina Wilhelmina Skeggs to be called to the bar along with her fast brother, to run against him in the race for the Lord Chancellorship? How, too, about the Church? Is "the fist instead of stick" beating the "drum ecclesiastic," to be the white hand of some fair cynosure of modern eyes, like the Reverend Antoinette Brown; and, in the teeth of St. Paul's warning against women opening their mouths in the churches, are we to find the churches resounding with women, who show that just there they will do nothing else? It does not matter, perhaps, either way, as professions are going. There is a change running on in the world which the wisest of us, perhaps, does not understand, and what it all means will be told, perhaps, by some philosophical historian to our children. Great as was the Diana of the Coppersmith, she passed away; and the most attached worshippers of the good old Ephesian faith—and there are some remaining, it is suspected—would find it difficult in a pilgrimage now-a-days to the famed site to possess himself of even a relic to remind him of the old greatness. The learned professions, which have stood untouched by the wreck of so much holier matter, is now under threat; and who knows but that—as the King of Dahomey has already advanced before us in recruiting his soldiery from the gentler sex—the same *cunabula nationum* may not be called on among ourselves, as the most progressive of people, to take all the honours of pill and bolus quant. suff., and of "draught and powders as before."

The subject will bear equally a smile and a sigh in contemplation, but as a matter of fact is less ambidextrous. The employment of women is one of the great unsettled problems of the age; and we, like the rest, perhaps, must be prepared to bear our part in the expense of the anarchy that must be expected to precede the solution. It is not only a very great difficulty, but one which every day tends to make greater. We have our women daily in greater actual numbers, in greater actual disproportion, with the concurrent phenomena of there being smaller means of employment in the proportion that there are greater necessities for them. The duties of the father to the daughter, of the brother to the sister, relax with the relaxation in morals that has been growing up, as to the rights on one side, and the claims to independence on the other. The maxim "Everyone for himself, and God for us all," comes into play earlier than it used to do, and finds its natural commentary in the self-supporting principle. The best of fathers, and the most devoted of mothers, will now give their children of either sex, at very early ages, the precious education to be derived from being left to their own resources; and the admiration of manly chivalry is now chiefly directed to that part of the loveliest portion of creation who show most pluck and spirit in making least appeal to its assistance. There is a surplus population, as regards females, of nearly a million in our midst; and, if inquiry were very carefully made, it might be ascertained that there are at this moment nearly as many women and girls dependent on their own industry and their own personal resources for support, as members of the other sex. It must not surprise us, therefore, if "What shall we do with our women?" prove as troublesome a question for us as for some other portions of the community, a question all the more troublesome that some of the channels that furnished them occupation in the time of our grandmothers—as spinning, weaving, and sewing—have passed from their hands to the cheaper agency of man and his machinery. There is no lack of objections to be urged against the introduction of women into employments already over-supplied, and which long custom, and a thousand associations which we are loath to part with, have hitherto made the exclusive appanage of males. But what are such considerations to the plea of the overruling necessity implied by an unoccupied moiety of the population? To live by their industry is as much the law of their happiness as it has always been of ours; and if we deny them the benefits of the law of free-trade in the offer of their labour, and some of us, keeping the monopoly of our Profession, seek to throw them exclusively on a few others, by what principle of justice shall we vindicate our advantage? How may we open to them certain alleys at the expense of the present possessors, and deny them, as by an Act of Parliament, entrance to all others?

We must here luckily, as in some other of the providential arrangements of society, leave affairs to the influence of the natural law; and there is this to be said of our profession—that it offers fewer affinities and would benefit them by fewer adaptations, than any of the other fields open to the competition of women. The studies of the Physician and the practice of the Surgeon are not attractive to the more delicate susceptibilities of the female mind; and it is probable that, if a fierce competition brought its natural results, and they were even admitted amongst us in large numbers, their tendency to the conjectural in reasoning and to the emotional in character, would fail to attract to these interesting rivals any formidable amount of public confidence. The chances as Apothecaries might possibly, as foreseen apparently by the new neophyte, be more encouraging; but it is not unlikely that the actual result would be, even if many followed the example of the interesting young lady who passed the Hall on Thursday week, that we should see them contenting themselves with some specialty, as the diseases of women and children, or lapsing into the time-honoured institution of midwifery, or supplying well new wants or old wants better, in becoming appendages to educational institutions, or living in medical charge over aged and infirm gentlemen, and so on.

If, then, as we think, there be so many tenable grounds for admitting against us whate er competition our lady friends may think proper to offer us in the course of time, we may console ourselves with the assurance that we are not likely to meet with any very important losses in actual fact from the innovation; and on the principle that a deluge after our time offers considerations only in the secondary order of things, we may perhaps conclude that there is no very pressing necessity for sending our new petticoated colleague forthwith to Coventry, and that we may permit ourselves to look on the interesting incursion with which her advent threatens us with a reasonable amount of professional equanimity.—I am, &c.,

April, 1864. SCRUTATOR.

[Miss Garrett has not passed her examination for a licence to practise Medicine, as our witty correspondent appears to think; she has passed only her *preliminary* examination.—ED. MED. CIRCULAR.]

"STRUCK DUMB."

To the Editor of the Medical Circular.

SIR,—Most of your readers, and indeed the public generally, have, no doubt, heard of and often used the phrase, *struck dumb*, but how many of them have ever *seen* such a case? Very few, I believe; in fact, I and many others have, for a long time, considered it to be rather a strong expression, than a thing likely to occur.

The following case has proved to me, however, that it *can* happen. And if you think it worth insertion in your valuable pages, you will oblige Yours, &c.,

A. ADAMSOM, M.R.C.S. ENG.

5A Holland street, Brixton, April 11.

On Saturday, the 2nd inst., I was called, at about seven o'clock, to see a boy of about sixteen years of age, a strong, active lad, of a sanguine temperament I found him in an intensely excited state, in consequence of the very sudden death of his father, which had occurred about four hours previously. He was perfectly conscious, and was busy comforting his poor mother, who had received a severe shock on the death of her husband. But from the moment he saw his dead father he remained *perfectly dumb*.

Fortunately, I had considerable influence over him, in

consequence of his having been pleased with my treatment of him for a late accident; so I stayed with him for some time, until he had become more calm. I then administered tr. opii. 3ss., and left him.

I went to seek a little girl, of about his own age, to whom he was much attached, hoping that the "power of love" might help to restore the "power of speech." It did so. About an hour afterwards they both waited on me. He was perfectly recovered, and was able to give me an account of the circumstances connected with the death of his father.

LEGAL INTELLIGENCE.

WORSHIP STREET.

CONVICTION UNDER THE MEDICAL ACT.

Mr. Edward Tucker Jenkins, of 159 Lever street, St. Luke's, was charged at the instance of Mr. James Ireland, a Medical man, with having unlawfully pretended to be a physician, doctor of medicine, and surgeon.

Mr. Sleigh, the barrister, conducted the prosecution, and Mr. Nind appeared for the defence.

Mr. Sleigh said he appeared there to conduct a prosecution against the defendant, who was charged in the summons issued against him with having on certain days and times held himself out and professed to be a physician, doctor of medicine, and surgeon, thereby implying and leading the public to believe that he was legally and properly registered as such. He should be able to prove by evidence that this defendant had for some years carried on the business of a doctor of medicine and surgeon both in the New North road, and also in Lever street, St Luke's; that he had issued cards with that designation, calling himself "Dr. Jenkins, surgeon and accoucheur, 150 Lever street, late John's row, and at 11 Great Prescott street; advice gratis from 9 to 11;" and that at his private residence he intimated he was at home from 10 o'clock till 10 o'clock, so that he must be there all night, while he also had a brass plate on his door calling himself a surgeon and accoucheur. He was thus ostensibly carrying on the profession of a surgeon, doctor of medicine, and accoucheur, while he was not on the Medical register at all, and had no title whatever to any such designation. He should now prove all that he had stated, and would call upon the magistrate for the infliction of the full penalty of 20*l.*

Mr. Nind said that notwithstanding the serious results alleged to have been likely to follow his client's practice, no proof of a single case of such consequences had been adduced. He should be able to prove, from documents he held in his hand that the defendant was a man of ability, and worthy of the confidence which had been placed in him. It was true that he was not licensed or registered; but his father, who had been in the profession for years, was so. The defendant had been assistant also to his father, who had just died. In addition to all this he had letters from Messrs. Partridge, Ferguson, Tanner, and Lyons, of King's College Hospital, speaking of his diligence, readiness, and intelligence while assistant dispenser there, showing he had the good opinion of all the medical officers, and numerous other testimonials, expressing a conviction of his perfect competency as a medical man. He attributed the prosecution to jealousy on the part of the Medical Profession. But he could not defend his client's conduct. However, the defendant intended shortly to pass an examination at Apothecaries' Hall, and he hoped that before twelve months expired he would legally be upon the register.

Mr. Sleigh warmly protested against such an unjustifiable imputation upon the Medical Profession as that just made of jealousy of the alleged success of the defendant. Immediately on hearing the announcement of the defendant's father's death he was about to rise and withdraw his pressure for the extreme penalty, and even now he wished to do so, in consideration of such a domestic misfortune. He and his clients would therefore be satisfied with any penalty the Bench might think would meet the case, and, so far from there being any feeling beyond vindicating the honour and the respectability of the profession, they would not ask for any costs, not even those of the summons.

Mr. Nind expressed his client's appreciation of this friendly act, and Mr. Leigh sentenced the defendant to a penalty of 5*l.*

DEATHS.

BLACK.—On the 30th ult., at Marcus square, Newry, T. H. Black, M.R.C.S.E.

BOULTON.—On the 1st inst., at Stone, Staffordshire, J. Boulton, L.S.A., aged 56.

DIXON.—On the 4th inst., at Hackney, F. B. Dixon, M.D., aged 50.

HERBERT.—On the 29th ult., J. Herbert, L.F.P., & S. Glas., of Airdrie, Lanarkshire.

HORAN.—On the 6th inst., at Cootehill, Susanna, the wife of Thos. Horan, M.R.C.S.

MAYNE.—On the 9th inst., Dr. R. Mayne, of Upper Gloucester street, Dublin, aged 53.

PARKES.—On the 10th inst., J. Parkes, M.R.C.S.E., of The Wylde, Bury, Lancashire, aged 57.

PORTER.—At Caistor, Lincolnshire, G. M. Porter, L.S.A.

SMITH.—On the 13th of Feb., at Ferozepore, J. C. Smith, Assist.-Surg. 1st Battalion 19th Foot, aged 31.

TURNBULL.—On the 8th inst., at Aldroughty, W. Turnbull, Surgeon, Madras Service.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 12th inst., and when eligible, will be admitted to the Pass Examination:—Algernon Ewen, Henry Weekes, John Gill, Jabez Thomas, Robert Stuart, W. H. Butler, J. H. Walters, B. C. Cowing, R. B. Nowell, and S. W. Bushel, Students of Guy's Hospital; O. W. Berry, A. R. Verity, A. Fennings, T. S. Dowse, and H. J. Foulds, of Charing-cross Hospital; R. P. Simpson, H. A. Husband, and Edward Bryan, of St. Bartholomew's Hospital; G. A. Brown, J. Oakley, and R. M. Hickman, of King's College; C. J. Harris, C. W. Huet, and J. C. Worthington, of the Middlesex Hospital; E. C. Shopfree, William Hoffmeister, and W. C. Cass, of University College; J. F. Sargent and W. J. Land, of St. Mary's Hospital; Richard Ley, London Hospital; W. B. Coghlan, St. Thomas's Hospital; W. A. Parsons, Birmingham; and W. E. Richardson, Leeds.

On the 13th inst.:—J. T. Langley, William Iliffe, G. F. Webb, T. L. Place, A. C. Farrington, H. C. Rogers, Theodore Fennell, H. R. G. Rust, and Edwin Renshaw, Students of St. Bartholomew's Hospital; Henry Denne, Henry Morris, H. S. Taylor, G. R. Raine, and Joseph Batteson, of Guy's Hospital; E. M. Spooner, E. S. Wright, Disney Sharp, and Alfred Walker, of the London Hospital; R. S. P. Griffiths, N. B. Major, and F. G. Atkins, of St. Mary's Hospital; Howard Barrett, G. C. Searle, and F. W. Underhill, of St. George's Hospital; J. B. Kerswill and W. J. Todd, of King's College; Alfred Jones and John Swindale, of the Middlesex Hospital; T. H. Tidswell, of the Charing cross hospital; F. B. Nunnely, of University College; C. G. M. Lewis, of Birmingham; J. H. Hughes, of Dublin; T. R. King, of Edinburgh; and George Bambridge, of Leeds.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, April 7, 1864:—William George Beardsall, Worksop, Notts; Arthur Roberts Firth, Richmond, Surrey; Henry Rayner, St. Thomas's Hospital; Joseph Bower Siddall, St. Thomas's Hospital.

As an Assistant:—James Williams, Wokingham.

The following gentlemen also on the same day, passed their First Examination:—Franklin Gould, King's College; William Iliffe, St. Bartholomew's Hospital; George Warcup Malim, Guy's Hospital.

THE BURNING OF QUEEN'S COLLEGE, CORK.—At a special meeting of the Visitors of the College held at Cork on Tues-

day week, at which the Lord Chancellor and other influential Visitors were present, the subject of the burning of the College at Cork amongst other matters was investigated. It was stated that the progress of the College was in every way most satisfactory, and that the damage caused by the fire would be speedily remedied. A letter was read from Dr. Bullen, withdrawing every statement he had made reflecting on Sir Robert Kane, and an ample and unqualified apology made for the unjust and erroneous impressions under which he had laboured. In the following remarks of the Lord Chancellor all must acquiesce, and rejoice in the complete exculpation which they afford of a most distinguished and estimable public servant. His Lordship said: "The object of our inquiry has now been achieved, having received that full, explicit, and unequivocal admission from Dr. Bullen of the incorrectness of the statements which he feels have reflected injuriously on Sir Robert Kane, and which no one who heard them could hesitate to say must, if well founded, have utterly disqualified Sir Robert Kane for the position of President of this institutian. The functions of the Visitors are now discharged, and it will be our duty to return to his Excellency the document which has just been read. What action the Government may take in reference to the result of the proceedings is not for me to say; all I can say is that we as Visitors have no authority to do more than receive this letter; it will be for others to act upon it as they may think proper so far as the dignitaries of this College and its interests are concerned, as far as regards the character of the President of the College, and through him of all its students. I must say that I feel deeply gratified that Sir Robert Kane no longer labours under the imputation cast upon him by Professor Bullen. I do hope that never again in the annals of this College will there occur such a correspondence as has been brought under the notice of the Government in connection with these proceedings. I have nothing further to say than once more to express my gratification at the result which has been so satisfactorily arrived at, and to hope that the future progress of the institution will be equal to that which it has hitherto maintained, gratifying to all connected with it, and creditable to the character of the country at large." The visitation then ended, and the Visitors were conducted by Sir Robert Kane and the Professors through the various departments of the College, the inspection of which elicited warm expressions of satisfaction from the distinguished individuals who had undertaken the duty of investigating the matter. Sir Robert Kane was warmly congratulated on the result of the proceedings, and enthusiastically cheered by the students.

NATIONAL DENTAL HOSPITAL.—A concert was given on the 11th inst., in aid of the funds of this institution, under the superintendence of Herr Schloesser. The principal performers were Madame Lemmens-Sherrington, the Misses Whytock, Jenkins, Stabbach, and Freeth; Messrs. Oberthur, Lansmere, and Burdini. M. Lemmens, organist to the King of the Belgians, performed on the harmonium with his usual effect. The concert was attended by a numerous audience, who appeared fully to appreciate the exertions of the talented artistes who so generously placed their services at the disposal of the committee of the hospital. It is to be hoped that the concert will aid in making the hospital a permanent institution, by the purchase of the premises at 149 Great Portland street.

UNIVERSITY COLLEGE HOSPITAL.—The annual dinner in aid of the funds of the University College Hospital took place last week at Willis's Rooms, St. James's Mr. Charles Dickens in the chair. The usual loyal and patriotic toasts having been drunk and responded to, the chairman proposed the toast of the evening, "Prosperity to University College Hospital. He said there were three cogent reasons why this charity should receive the generous support of the public. The first was that the neighbourhood in which it was situated was a poor one, and from what he had heard the help rendered to the inhabitants by the hospital was most valuable. Yet it was not a poor neighbourhood like the east end of London, for there were numerous streets and squares filled with rich people. If these persons could only be induced to subscribe a guinea annually, the hospital would be a rich one. Secondly, it appealed to the gratitude and spirit of the whole country, for the medical school attached to it was one of the most efficient in England, and had sent out to all parts some of the brightest ornaments to the Medical Profession. Lastly, it represented liberty of opinion in its widest sense. It excluded no one —doctor, student, nurse, or patient, on account of his religious principles. In doing this they had rendered incalculable service to the community at large. It must not be forgotten either that the hospital was connected with University College, the freedom of which from religious bias had been instrumental in laying the foundations of the Queen's Colleges in Ireland, and in rubbing the eyes and quickening the steps of the old Universities in this country. Indeed, it was hard to say where its influences ended, for the Parsees had carried its teachings into the remotest cities of India, and students at least had founded a hospital in the Celestial Empire. There were men of strong common sense to be found in all nations, no matter how yellow their skins, how long their pigtails, or how complicated their turbans; and these were the men to whom the teaching would do good. As an instance of this a Hindoo merchant had last year made a most munificent donation to its funds. Thus it did good not only to the sick but to the sound. He hoped he had said enough to enforce its claims on those who held the gift of fortune in trust. He would conclude by proposing the toast of "Prosperity to the University College Hospital." The toast having been drunk, Mr. Jaffray announced subscriptions to the amount of nearly 1,500*l*. "The health of the Chairman" was then proposed in a highly eloquent and eulogistic speech by Mr. Marshall. The toast having been responded to and replied to, Mr. Shirley Brooks proposed "The health of the Trustees and other Officers of the Institution" in a humorous speech. "The Medical Officers," "The Chaplain, the Rev. Dr. Stebbing," and several other toasts, were then drunk, and the meeting separated. Beside the chairman, there were present Dr. Roget, Professors Helmholtz, Goldstucker, Masson, and Williamson, the Rev. Dr. Stebbing, Messrs. T. Hughes, J. Forster, Shirley Brooks, Julian Goldsmid, J. Hingwood, H. Kingsley, and many other gentlemen connected with literature, science, and art.

MEDICAL ORATORY IN AMERICA.—The Academy of Medicine does not, like its great prototype of Paris, maintain a very high order of oratorical reputation. In spite of the unwearied efforts of its worthy President to render its sessions highly scientific, its discussions are too generally diffuse and pointless. The fault rests with the members. As a profession, we cultivate far too little the art of speaking. In the Academy of Medicine of Paris, the very highest order of rhetoric is often displayed. In France the members of the Medical Profession perfect themselves early in public speaking, and hence the vigorous and racy style of discussions in all their societies. Every speaker expresses himself with that ease and elegance which add such a charm both to the oral and written discussion. But a loose and random style of speaking is not the only fault of those who enter the arena of debate in our societies. Not unfrequently language is used by no means befitting a scientific association. Many must have been pained, if not shocked, a few evenings ago, to hear a member of the Academy of Medicine, in open session, characterize an act of the President by an expression altogether unworthy the gentlemen who uttered it, and unbecoming the occassion. Such remarks should never be tolerated, even in private, much less in a society which boasts of its purity. No association can ever attain to any very commanding influence which allows its members to indulge in coarse and vulgar language. The Academy of Medicine shoud never permit such freedom of expression, and the member who persists in degrading himself by such language should not be allowed fellowship in any respectable society.—'American Medical Times.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, APRIL 20.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Hunterian Society, 8 p.m.—Mr. C. Bader, "On the Cure of Opacity of the Cornea by Gonorrhœal Inoculation."

THURSDAY, APRIL 21.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Prof. Helmholtz, "On the Natural Law of the Conservation of Energy;" Chemical Society, 8 p.m.—Mr. J. T. Way, "Philosophy of British Agriculture;" Harveian Society, 8 p.m.—Dr. Cock, "On Laryngismus Stridulus."

FRIDAY, APRIL 22.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Prof. Blackie, "On Lycurgus."

SATURDAY, APRIL 23.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On the Metallic Elements."

MONDAY, APRIL 25.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, APRIL 26.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Lectures on the Laryngoscope. Part I. By Philip C. Smyly, M.D. Dublin: Fannin and Co., Grafton street.

On the Economical Use of Fuel and the Prevention of Smoke in Domestic Fireplaces. By Frederick Edwards, jun. London: R. Hardwicke, 192 Piccadilly, W.

The Archives of Dentistry. No. I. London: John Churchill and Sons, New Burlington street.

Report of the Medical Superintendent of the Richmond District Lunatic Asylum, Dublin, for 1863.

On the Practice of Employing certain Substitutes for the Genuine Ingredients in some Articles of Daily Food.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor, may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

DR. S. W. J. MERRIMAN.—The notice has been received.

THE HARVEIAN SOCIETY.—The notice is inserted.

MR. ADAMSON'S letter is inserted.

SCRUTATOR.—The letter is inserted.

INFORMATION.—The effect of the mother's or nurse's milk upon the sucking child is sometimes very prejudicial, when the temper of the woman is excited, and she is, to use a common expression, thrown into a passion. Obstinate vomiting of the contents of the stomach, and when it is emptied, violent and persistent retching—diarrhœa, convulsions, and complete prostration, are evidences of the ill-effects produced by the introduction of the vitiated fluid into the child's system.

LAICUS.—In your case, try the effects of quiet and freedom, as far as is possible, from all sources of mental annoyance; at the same time, enjoin active physical exercise, either walking, riding, or driving.

DR. R. L.—It is asserted that iodine pushed to certain lengths will in the male subject cause atrophy of the testicles, and in the female the same condition of the mammary glands; moreover, it will cause a decrease in the size of other glands, especially noticeable, if they be enlarged; when given so as to produce salivation, it will then make the glands become enlarged. In the instance referred to, we would recommend the Bromide of Ammonium as the very best emmenagogue.

MR. GRIFFIN.—Received and inserted.

Guy's Hospital.—The Summer Session

commences on Monday, May 2nd.

MEDICAL OFFICERS.

Physicians—G. H. Barlow, M.D.; G. Owen Rees, M.D., F.R.S.; W. W. Gull, M.D.
Assistant Physicians—S. O. Habershon, M.D.; S. Wilks, M.D.; F. W. Pavy, M.D., F.R.S.
Surgeons—Edward Cock, Esq.; John Hilton, Esq., F.R.S.; John Birkett, Esq.; Alfred Poland, Esq.,
Assistant Surgeons—Cooper Forster, Esq.; Thomas Bryant, Esq.; Arthur Durham, Esq.
Obstetric Physician—Henry Oldham, M.D.
Assistant Obstetric Physician—Braxton Hicks, M.D., F.R.S.
Surgeon-Dentist—J. Salter, Esq., F.R.S.
Surgeon of the Eye Infirmary—Alfred Poland, Esq.
Assistant Surgeon of the Eye Infirmary—Charles Bader, Es
Aural Surgeon—J. Hinton, Esq.

LECTURES, &c.

Demonstrations on Cutaneous Diseases—S. O. Habershon, M.D.
Medical Jurisprudence—A. S. Taylor, M.D., F.R.S.
Materia Medica—S. O. Habershon, M.D.
Midwifery—Henry Oldham, M.D., and J. Braxton Hicks, M.D., F.R.S.
Ophthalmic Surgery—Alfred Poland, Esq., and C. Bader, Esq.,
Pathology—S. Wilks, M.D.
Comparative Anatomy—F. W. Pavy, M.D., F.R.S., and W. Moxon, M.B
Use of the Microscope—A. Durham, Esq.
Botany—C. Johnson, Esq.
Practical Chemistry—Thomas Stevenson, M.B.
Demonstrations on Manipulative and Operative Surgery—T. Bryant, Esq.
Clinical Medicine—Dr. Habershon, Dr. Wilks, and Dr. P vy.
Clinical Surgery—Mr. Cooper Forster, Mr. Bryant, and Mr. Durham.
Clinical Obstetrics—Dr. Oldham and Dr. Braxton Hicks.
Vaccination—Dr. Braxton Hicks.

Gentlemen desirous of becoming Students must give satisfactory testimony as to their education and conduct. They are required to pay 40*l.* for the first year, 40*l.* for the second year, and 10*l.* for every succeeding year of attendance, or 100*l.* in one payment entitles a Student to a Perpetual Ticket.

Dressers, Clinical Clerks, Ward Clerks, Obstetric Residents and Dressers in the Eye Wards are selected from the Students. Three House-Surgeons are appointed every six months.

Six Scholarships, varying in value from 25*l.* to 40*l.* each, are awarded at the close of each Summer Session for general proficiency; also a Governor's Prize of 10*l.*

Two Gold Medals will be given by the Treasurer—One for Medicine and one for Surgery.

There is a Voluntary Examination in October, in Elementary Classics and Mathematics. The three first candidates will receive respectively 25*l.*, 20*l.*, and 15*l.*

Mr. Stocker, Apothecary to Guy's Hospital, will enter Students, and give any further information required.

Guy's Hospital, April 9, 1864.

London School of Dental Surgery,

32, SOHO-SQUARE.—The SUMMER SESSION will commence on the 2nd of MAY, when Lectures on the following subjects will be given:—

The Anatomy and Physiology of the Teeth, by Mr. Ibbetson, on Mondays and Fridays, at 8 o'clock a.m.

Dental Surgery and Pathology, by Mr. S. Cartwright, on Tuesdays and Thursdays, at 8 o'clock a.m.

The Lectures for the Winter Session will commence in October, when Mr. Makins will give a Course on Metallurgy, and Mr. Hepburn on Dental Mechanics. Fees for Lectures qualifying for the Dental Examination at the Royal College of Surgeons, 15*l.* 15*s.*

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared

in a GRANULAR and EFFERVESCENT Condition the Constituent of the following MINERAL SPRINGS:—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT, &c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER:—
GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS:—
GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.
GRANULATED AND EFFERVESCING CITRATE OF QUININE.
GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in

addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON
MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.
143, NEW BOND STREET, LONDON.

Anatomy, Physiology, Pathology,

and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.—

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Briton Medical and General Life Association.

OFFICES — 429 WEST STRAND.

Directors.

CHAIRMAN OF THE BOARD—GEORGE H. BARLOW, M.D. DEPUTY CHAIRMAN—FRANCIS WEBB, Esq.

By the peculiarly equitable manner of dividing the profits, the Polices issued by this Association *become payable during the lifetime of the person Assured without extra Premium.* After having been in force a period of five years, all Policies are absolutely indefeasible and indisputable.

Declined and Diseased Lives assured at equitable rates.

New Business for the Year ending 31st December, 1863.

No. of Proposals.	Amount Proposed.	No. of Policies.	Amount Assured.	Annual Premiums.
3,147	£746,425	2,328	£567,453	£18,372 2 0

Capital Stock, £200,000. Annual Income, £130,000.

A reversionary bonus of 40 per cent. on the premiums for the past three years has just been declared.

Qualified Medical Attendants who are named by Proposers to this Association are consulted as Medical Advisers of the Directors, by whom all Medical Fees are discharged.

Every description of Life Assurance transacted; terms for which, with detailed Prospectuses and every information, may be had on application to JOHN MESSENT, F.S.S., *Secretary.*

N.B.—Special Advantages to Medical Practitioners effecting or introducing Assurances.

CLERICAL, MEDICAL, AND GENERAL

LIFE ASSURANCE SOCIETY.

13 ST. JAMES'S SQUARE, LONDON, S.W.

Established 1824. Empowered by Special Act of Parliament.

Directors.

CHAIRMAN—Right Hon. JOHN ROBERT MOWBRAY, M.P., Mortimer, Reading.

DEPUTY-CHAIRMEN { WILLIAM BOWMAN, Esq., F.R.S., 5 Clifford street, Bond street. / Sir CHARLES LOCOCK, Bart., 26 Hertford street, May fair.

HENRY W. ACLAND, M.D. F.R.S., Oxford.
PATRICK BLACK, M.D., 11 Queen Anne street.
Rev. THOMAS DALE, M.A., Canon Residentiary of St. Paul's.
CHARLES M. DEANE, Esq., Banker, Winchester.
JAMES DUNLAP, M.D., Queen's terrace, Windsor.
ARTHUR FARRE, M.D. F.R.S., 12 Hertford street, May fair.
Rev. JOHN E. KEMPE, The Rectory, St. James's, Westminster.
RD. HOWSON LAMB, Esq., Bragborough Hall, Rugby.
GERARD W. LYDEKKER, Esq., Harpenden Lodge, St. Albans.
ANDREW A. MIEVILLE, Esq. 67 Gower street.
Rev. JOSEPH MOORE, M.A., Buckland, Faringdon.
JAMES PAGET, Esq., F.R.S., 1 Harewood place, Hanover square.
GEORGE H. PINCKARD, Esq, Combe court, Godalming.
ALEX. J. SUTHERLAND, M.D., F.R.S., 6 Richmond terrace.

CREDIT SYSTEM.—On Policies for the whole of Life, where the age does not exceed 60, one-half of the Annual Premiums during the first five years may remain on credit, and may either continue as a debt on the Policy or be paid off at any time.

LOW RATES OF PREMIUM FOR YOUNG LIVES, with early participation in profits; and considerably reduced rates for Assurance without participation in profits, and for Term Policies.

ENDOWMENT ASSURANCES may be effected without profits, by which the sum assured becomes payable on the attainment of a spe ified age, or at death, whichever event shall first happen.

INVALID LIVES may be assured at Premiums proportioned to the increased risk.

PROMPT SETTLEMENT OF CLAIMS.—Claims paid thirty days after proof o death.

THE ACCOUNTS AND BALANCE SHEETS are at all times open to the inspection of the Assured, or of *Persons proposing to Assure.*

THE ASSURANCE FU ND already accumulated and invested on real and Government Securities, amounts to **One Million Three Hundred and Eighty-six Thousand Pounds.**

THE REVERSIONARY BONUS at the Quinquennial Division in 1862 averaged 46 per cent., and the Cash Bonus 28 per cent., on the premiums paid in the five years. *The next Division of Profits* will take place in January, 1867.

Tables of Rates, and Forms of Proposal, and the last Report, showing the financial position of the Society, can be obtained from any of the Society's Agents, or of GEORGE CUTCLIFFE, *Actuary and Secretary.*

N.B.—A FEE OF ONE GUINEA IS PAID TO THE MEDICAL ATTENDANTS OF ALL PERSONS PROPOSING TO ASSURE.

Society for Relief of Widows and

ORPHANS OF MEDICAL MEN.—INSTITUTED 1788.—Incorporated by Royal Charter, 1864. The Seventy Sixth Anniversary Dinner of this Society will take place on Saturday, the 28th May at the Albion Tavern, Aldersgate street.—Thomas Arthur Stone Esq., President and Trustee, in the Chair. Tickets one guinea each, to be obtained from the Stewards, from the Secretary, or at the Tavern. Dinner to be on the Table at half-past six o'clock precisely.

Any registered Member of the Medical Profession residing in the county of Middlesex, or within the limits of the London District Post, is eligible as a member of this society, at a subscription of Two Guineas a year. Widows and Orphans of members of not less than two years' standing are eligible for relief, and to such applicants relief was granted last year to about 2,000*l.*

S. W. J. MERRIMAN, M.D., Secretary.

53, Berners street, W.

Emperor Life and Fire Assurance

SOCIETY. 78 Cannon street West, and Queen street, London.

Seventy per cent. of the profits given to the assured.

Policies made payable during the lifetime of the assured, without extra premium.

Claims paid to the Policyholder within Fourteen days after satisfactory proof of death.

Doubtful lives assured on equitable terms.

Stamps and Medical Fees paid by the Office.

The usual commission allowed to the Medical Profession introducing business.

Prospectuses and Proposal Forms forwarded on application to

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 244.)

The Preventive Treatment.

Prec. 8.—When a woman suffers from a cough during labour, it is the best plan to give her fifteen drops of Battley's solution of opium (unless there should be any symptom present contraindicating its use) immediately on delivery, and to repeat the dose in half an hour if the cough be not relieved. I have noticed that if a patient suffers from a cough during labour, it is generally worse for two or three hours after delivery. The loss of blood is nearly always free in such cases, from the violent jerking and straining to which the cough gives rise. The cough, in the greater number of instances, is merely sympathetic; very little mucus is secreted, and although it is troublesome for a few hours after the termination of labour, it generally disappears altogether in a day or two.

Prec. 9.—Having separated the infant from the mother, unpin the binder, which, as the patient is lying on her left side, can be effected without the slightest movement on her part; then pass the hand next to the skin, in order to ascertain the condition of the uterus. If there should be no evidence of the existence of a second infant, and the uterus be felt *contracted* upon the placenta, repin the binder firmly. The tightening of the binder after the birth of the child is necessary, because it has now become quite loose, and it acts beneficially in stimulating the uterus to contract. If the uterus should be found *large and flabby*, we ought not to trust to the pressure of the binder. In such a case it is better to leave it unfastened, and to place the hand next to the skin over the fundus of the uterus. No kneading action should be used with the hand, because it may induce irregular contraction, or separate only a portion of the placenta, and bring on severe hæmorrhage. The pressure should be but a little more than the weight of the hand, and equable over as large a surface of the fundus as possible. The slight pressure of the hand on the uterus before the detachment of the placenta resembles in utility the slight tightening of the reins in the driving of a spirited horse. The horse knows well enough then that there is some one looking after him, and he is quiet; but only let him find out, from the perfect slackness of the reins, that he is without a driver, and he at once bolts away. So in the case of the uterus, the slight pressure of the hand lets the uterus know, as it were, that it is under judicious restraint. Slight and equable pressure on the uterus is as useful in the prevention of hæmorrhage as strong pressure is in the treatment of flooding.

Prec. 10.—The delivery of the placenta is the most important and anxious part of a natural labour. Women regard that accoucheur the most skilful who brings the child into the world most quickly; whereas, if they knew better, they would judge his skill rather by the way he managed the delivery of the placenta than that of the child. Many women have had their cheeks blanched, their constitutions more or less injured, or have lost their lives, from mere want of care on the part of the attendant, in the management of the delivery of the placenta.

The expulsion of the placenta may be effected by the unaided efforts of the uterus, or with manual assistance. If the uterus should expel the placenta immediately or shortly after delivery, we may rest pretty satisfied that the patient will not flood. No doubt if we were to wait long enough, the uterus would expel the placenta in the greater number of cases; but experience has taught us that allowing the placenta to remain in the uterus for hours is by no means safe. The uterus soon after labour usually contracts with merely sufficient force to detach the placenta, partially or entirely, but not to expel it. While the placenta remains attached in its whole extent, the patient is safe from hæmorrhage; not so when it becomes detached; it then acts as a foreign body. It prevents the uterus from contracting to its minimum, which is Nature's great and chief means for arresting the flow of blood through the uterine vessels. I do not wish it for a moment to be understood that I recommend the hasty removal of the placenta. To remove it too hastily is quite as bad as to remove it too tardily. The chief difficulty we have to get over by considerable experience is, in fact, the knowing when to take it away, and when to leave it alone.

After the patient has complained of two or three "pinching pains" in the hypogastric region, we should try and ascertain whether the placenta has become detached or not. If the binder has been tightened immediately after labour, the first thing is to loosen it to enable the left hand to be placed over the uterus to keep it steady. On making a vaginal examination with the right hand, if the placenta be detached, we feel readily the insertion of the cord, and a considerable portion of the placenta around, and on removing the finger it is generally observed covered with blood. The portion of the cord lying externally is also usually flaccid. If the placenta be not detached, the cord will be felt passing into the cavity of the uterus, but no portion of the placenta will be within reach; and the vessels of the cord will be noticed distended with blood. The above are the signs mentioned in obstetric works; nevertheless, they are not to be taken as infallible; for instance, the placenta may be undetached, and yet the insertion of the cord, and a portion of the afterbirth be felt, either from the uterus being firmly contracted upon the placenta, and bringing them within reach of the finger, or from the afterbirth being situated unusually low. Again, the placenta may be detached, and yet no blood be noticed on the finger, on account of it s collecting in the bag of the membranes; the vessels of the cord may be distended from the uterus remaining firmly contracted on the placenta, and keeping the blood confined with them; we may find great difficulty in reaching the placenta, or may not feel it at all from its lying loose in the upper part of the uterus, or from a long vagina. These are not imaginary fallacies; every one of them have come under my observation. In the great majority of cases, however, if we should feel the insertion of the cord, and a considerable portion of the placenta besides, and we observe the finger covered with blood, and the cord flaccid, we shall be correct in considering the placenta detached.

There is a great diversity of opinion amongst Medical men as to how long a time should be allowed to elapse after delivery, before measures should be taken to remove the placenta. Some remove it almost immediately; others never think of taking it away before a quarter of an hour at least after labour. In my own practice I have no fixed time at all. As soon as I am sure it is detached I remove it. We know that sometimes the uterus expels the child and placenta together, and with excellent result; and there is no reason if the placenta be detached by the pain that expelled the child, why we should not then remove it at once. One important precaution is to remove the placenta *during an uterine contraction.* If a placenta, lying loose in the cavity of the uterus, be removed *during* an uterine contraction, a few minutes after labour, hæmorrhage will be less liable to follow, than if it were left alone for half an hour, and then were to be taken away in the absence of an uterine contraction. The practice of some, who remove the placenta within a few minutes after labour, as a rule, not caring as to whether it be detached or not, is very reprehensible We must first feel certain that the placenta is lying loose in the uterine cavity, or in the vagina; next, from the

the better to embrace the womb. This circle may be of one piece, but should be separable into at least two equal parts—the line of separation had better correspond with the mesial vertical line of the body—and these parts should admit of divarication and approximation by means of a screw; the circle should be encased in vulcanite, and, moreover, that there be no interruption on the surface presented to and compressing the uterus, the vulcanite must be elastic enough to stretch and yield with the segments of the compressing circle as they are sundered, and of again, through its resiliency, contracting as they are screwed together. By using a bent screw, with its convexity corresponding to that of the circle, the peripheral margin of the circle can be—at least, on either side—inclined inwards, *i. e.*, toward the abdominal cavity and the uterus, in order to grasp the latter more efficaciously. This screw would run from side to side, its head being directed to one ilium, its point to the opposite. The circle may be of wood, or of steel, or of any substance which will not yield with the pressure, and, by means of a screw, can be attached to the uterine extremity of the body of the instrument.

Should this arrangement not prove adequate, the circle may be divided into many pieces, the lines of division being some vertical, others horizontal; and these, by properly-adapted screws, may be all regulated in such a manner as to somewhat resemble the fingers of the hand.

With this instrument we gain an immense power, possessed of this advantage, that we can use it as seems best to us in each case, and adapt it as occasion may require.

We may in some instances dispense with the belt, the rest of the instrument being sufficient to maintain itself *in situ*.

Besides this method of applying a compressing force, we can employ pressure in the following manner:—An India-rubber bottle, covered or not with spongio-piline—a suggestion which I have borrowed from Dr. Greenhalgh—is to be passed, *uninflated*, into the vagina, and fairly up against the os and cervix uteri: the bottle must be large enough to engage, when even partially inflated, the entire of the vaginal canal. Sometimes it may be necessary to have it fully inflated. After its introduction into the vagina, the bottle is inflated, and the air retained by means of a stop-cock affixed to the tube through which the air is injected. This tube, made of metal encased in vulcanite, or of stout gutta-percha, or very strong vulcanite, must be of proper strength, so that pressure may be transmitted by means of it from the body of the instrument to the bottle lying against the mouth and neck of the womb; its curvature must likewise correspond with the vaginal axis; it is to be connected with the body of the instrument by a flat circular screw.

In this manner direct pressure, if desired, can be exercised upon the uterus, externally, and internally through the vagina. Bleeding will be effectually arrested, the vagina being thus well plugged, so that no blood can escape into it; while the uterus, firmly grasped by the circle of the instrument, is made to contract, and thus prevent the collection of blood in its interior, if, indeed, the uterine vessels can permit any to escape after the instrument has been applied. We need not allow the labia, pubis, or the perinæum to be at all compressed, because, by giving to the body of the instrument a proper sweep, such is obviated.

Instead of the screw and hinge, for the purpose of regulating the degree of curvature and compressing force of the body of the instrument, as above mentioned, we may adopt a *sliding* joint, which could be rendered immovable by means of a screw; and perhaps this would be more advantageous, as the instrument could be taken to pieces and rendered more portable.

The advantage of the vaginal compress, independently of its action in preventing a discharge of blood, is, that it counteracts any tendency to inversion or descent of the womb from the downward pressure of the uterine circle of the instrument.

I propose calling the apparatus the uterine compressor. It is applicable, not alone to cases of hæmorrhage, but, as above stated, to those in which uterine, ovarian, or other forms of pelvic tumours have become developed, the growth of which tumours can in this manner be controlled, if not altogether arrested.

Claverton terrace, St. George's square,
May, 1864.

HOSPITAL REPORTS.

OPERATIONS AT KING'S COLLEGE.

The first was a case in which a sequestrum of bone was removed from the thumb of the right hand.

The history was as follows:—Some time previously that form of inflammation known commonly by the term "whitlow" had attacked the thumb; the periosteum had become implicated in the inflammation, suppuration had supervened, and at a later period necrosis of the bone of the distal phalanx. The dead bone, acting as any other kind of foreign body, had kept up a semi-purulent discharge from the opening in the integuments: having, however, at length become separated from the living tissues around it, so as to be almost completely isolated—except where a few granulations bound it down—Mr. Fergusson proceeded to seize this necrosed portion with an ordinary forceps, and to extract it, which he did without any difficulty. In his remarks subsequent to the operation, he said that this was a case in which some surgeons would amputate, and that he had often been called in for consultation by men who were in doubt as to the advisability of leaving on a member in a condition such as that now under observation; that there were other surgeons, who advised neither amputation of the thumb nor removal of the dead bone, but who advocated the leaving the process of separation and casting off wholly to nature. From the views of both these classes he entirely dissented; amputation was very seldom necessary, and to leave the entire process of separation and casting off to the unaided efforts of nature was decidedly wrong, and baneful to the patient, inasmuch as a constant discharge is maintained by the dead bone, which is just as much a foreign body as would be a rusty nail in the same situation: independently of this objection, the processes would take too long a time for their completion. The proper surgery for such cases was that put into practice in the present instance. Sometimes it may be necessary, in lifting the bone from its bed, to give it a pull in order to separate it from any granulations to which it may be attached.

When the necrosed bone has been taken away, new bone will be thrown out to replace it, and as thick a phalanx will be formed as existed before the disease; the thumb also will be as useful as hitherto, or, at least, very nearly so, and even should anchylosis result, it is far better to have an anchylosed thumb than none at all.

Mr. Fergusson thinks this operation as much a capital one as any of those so called; and the surgeon has as much to boast in saving so valuable a member as a thumb, as he has in sweeping off a leg, a thigh, an arm, or in removing a calculus.

CASE II.—URETHRAL FISTULA.

The subject of this operation was a young, strong man; Mr. Fergusson had operated upon him on former occasions, and had reduced the opening in the urethra to its present small dimensions, it having been about an inch and a half when the first operation was undertaken.

The opening, about two inches from the meatus urinarius, was sufficiently large to admit through it the exit of a probe from the urethra. Hard and hypertrophied portions of integument having been taken away, and the margins of the aperture made completely raw by the dissecting away of the entire ring of tissues, which immediately surrounded the opening, they were brought into perfect opposition and maintained in that condition by means of two thread sutures.

A second fistula was treated in exactly a similar manner. No catheter was passed after the operation.

The previous procedure had consisted in turning back the fore skin under the opening, and then uniting it posteriorly with the skin of the penis.

Mr. Fergusson alluded to the difficulty of procuring union in these cases—first, because the urine was so very likely to get into the new-made wound, and so induce an action wholly inconsistent with its union; and secondly, because in a great many instances the sutures ulcerated out too rapidly.

CASE III.—FUNGUS HEMATODES OF THE PALM OF THE HAND.

The patient was a young woman of spare and delicate habit, with reddish hair, fair, florid complexion, and slender build.

Upon the inner or ulnar side of the palm of the hand there was a reddish black mass, of a consistence somewhat resembling a softened liver, and in colour not unlike the appearance presented by a piece of cotton wool soaked in blood and allowed to become coagulated; in size it was about equal to a good-sized fresh nutmeg. Sweeping the knife first along the outer or radial margin of the base of this mass, and again along the inner so as to circumscribe it by one oval-shaped incision, Mr. Fergusson dissected it up from off the palm of the hand, lifting it as cleanly as possible away from the tendons, but without at all cutting them.

Hæmorrhage during the operation was arrested by compression of the radial and ulnar arteries at the wrist, so that very little blood was lost; when the operation was concluded, and as much as possible of the diseased tissues removed, pledgets of lint were placed over the bleeding vessels, and were then tightly enveloped in the folds of an ordinary bandage.

The history attached to the case is as follows:—About two years ago a small ulcer with a very suspicious appearance of malignancy came upon the inner part of the palm of the hand: as, however, the patient was very young, and as cancer in this situation is extremely rare, it was, at the time, considered to be at least doubtful in its character. Proving rebellious to all the ordinary methods of cure for simple or benign ulcers, it was treated by caustics, and would, under the use of them, nearly get well, but never quite so; as soon as it had almost healed, it would remain stationary for a little time, and then break out afresh.

She married, and gave birth to her first child: the disease again returned, and with each return it seemed as though a new disease had sprung up.

The patient placed herself under the treatment of a herb doctor, and whilst under his care (?), owing to the fact of there having been taken no active measures to stay its progress, the disease steadily advanced until it came to assume its present condition.

The reddish black substance was really nothing more than a mass of coagulated blood, that fluid having been poured out from ruptured vessels, and having subsequently become coagulated. Mr. Fergusson declared it to be one of the best specimens of fungus hematodes he had ever seen, and that it clearly showed the fungus to be a mere blood-clot, a dead material, possessed of no vitalisation whatever, nor of any particle rudimentary of organisation; it was the result of malignant ulceration.

There was a complete separation of this dead material from the diseased yet vital tissues subjacent, as was evident by the facility with which it was removed, so as to display the ulcerated surface, whence it has derived its origin. Sometimes, owing to its connection with the living structures, the base of a fungus appears to be vitalised; but this appearance is deceptive, and not by any means real. There are, again, other cases in which the entire mass seems animate, and this semblance of life is increased by the oozing of blood from the surface. This also is deceptive, and the oozing takes place in exactly the same manner as when a sponge, saturated with blood, is squeezed and made to give out from its surfaces the fluid with which it is filled.

Fungus hematodes is now a rare disease. Mr. Fergusson stated that he had met with a large number of cases in his earlier days, but that of late years, even when his practice had become extended, he saw, comparatively speaking, little or nothing of the affection. This, he said, arose not from any alteration in the disease, but from an alteration, an improvement in the treatment; surgeons of the present day not allowing this fungating stage to supervene, if the patient should have applied sufficiently early.

In the present instance it was feared that the disease had seized deeper than at first might be suspected, perhaps too deeply not to return after these operative measures; yet it was quite right to adopt this procedure and thus make an attempt to save the hand, before resort was had to amputation of the limb.

If subsequently the disease returned it might thus, judging from the present condition of parts, be impossible to save any part of the hand except the thumb. It was doubtful if aught would suffer for the preservation of life than amputation at some one or other part of the arm: the patient, however, wished to give the present mode of operation a trial.

Mr. Paget had concurred in the opinion of amputation formed by Mr. Fergusson.

CASE IV.—ENCYSTED OR OVARIAN DROPSY, COMBINED WITH A FIRM SOLID TUMOUR IN THE PELVIS.

This patient had been tapped five weeks since; it was the first occasion of the operation, and the fluid then removed was of a sero-sanguinolent character.

An opening having been made in the tegumentary tissues by means of a knife, a siphon-trochar to which was attached a caoutchouc tube was, not plunged, as some practise, but passed into the sac by a boring motion, similar to that used in trephining. The fluid that came away was of a thick, albuminous consistence, and in colour could be compared to nothing better than coffee-grounds, or sago in which port wine had been mixed. As the trochar was of large calibre, there was not any impediment to the escape of the fluid.

The patient's appearance was not indicative of any great amount of suffering or deterioration to the general health dependent upon the disease.

In all these cases of tapping, Mr. Fergusson adopts that position on the part of the patient which he was the first to introduce, namely, placing her on her side, and allowing her head to be very slightly elevated. The head should be raised only to that degree consistent with the ease and comfort of the patient. There is no occasion whatever for the use of the sheet around the abdomen, as practised in former days, since fainting will *not* occur when the cyst is emptied.

The advantages gained by having a large calibre trochar and a long piece of tubing attached to it are:—First, there is no obstruction to the exit of the sac contents, unless, indeed, they should be very thick and almost semi-solid; and the patient may be allowed to be upon her back or side—just as she pleases—and in the centre of the bed. Besides, by using this kind of instrument and the appliances resorted to on the present occasion, the parencentesis can be performed in a very much more cleanly manner than when we employ the ordinary trochar and canula.

The operation for ovariotomy was deemed inexpedient for two reasons—first, because of the solid nature of the pelvic tumour, and, secondly, because it was so immoveably fixed in its position.

Mr. Fergusson here alluded to the immense advantages of that mode of teaching which he had always enjoyed and carried into practice; the plan to which he made allusion was that of conveying instruction through the eyes rather than through the ears. He had always acted upon this plan, and those who had studied under him could testify to its success. "Lend me your ears" is a trite and hakneyed expression, but he preferred to render it, "Lend me your eyes and hands," being fully assured from the experience he had as a public teacher, that it was the best, if not the only, mode of learning, which sought to acquire knowledge by seeing the thing done and then by doing the same whenever opportunity presented.

CASE V.—NECROSIS OF THE LOWER PART OF THE SHAFT OF THE FEMUR, AND REMOVAL OF THE DEAD BONE.

This case presented a complexity of disease; in addition to the necrosis of the femur there had been disease of the knee-joint. The method of treatment to be pursued is, first, to take away the dead portion of the thigh-bone, and then to excise the knee-joint. This had been performed on a previous occasion, and the boy did well so long as he continued in the hospital; he had, however, been removed by his friends before anchylosis of the joint had become perfect. The newly-united parts were neglected, and the limb, from too early use, assumed a bent position, the degree of curvature being such as to render progression difficult. The operation upon the knee had therefore to be repeated, and a wedge-shaped piece to be removed: six weeks had scarcely elapsed since it had been done, and yet the limb was in a most excellent condition, and without doubt would be a serviceable and useful member.

The other leg had become permanently flexed, and that too at a very awkward angle. This had arisen from the manner in which the little patient lay, so as to obtain most ease, while he was confined to bed by the disease.

To-day portions of dead bone were taken away, which were lying at the bottom of the wound, whence had kept flowing away that kind of discharge indicative of the presence of such pieces.

This was the second instance of disease of the knee-joint, complicated with necrosis of the shaft of the femur, which had come under the notice of Mr. Fergusson; both he had treated in the same manner, namely, by cutting away the diseased mass from the femur first, and then by excising the offending joint. Both had turned out successfully. In the present instance, one pretty large sequestrum and several smaller fragments were brought away.

CASE VI.—NECROSIS OF THE METATARSAL BONE OF GREAT TOE.

The last case was that of a young girl who was a patient, from necrosis affecting the metatarsal bone of the great toe. The sinus leading down to the diseased bone having been enlarged, the latter was cut down upon and extracted; so small, however, was it, that none but a very practised finger and eye could recognise it, and it could scarcely be imagined to have occasioned so much mischief and distress.

When the bone was well scraped by means of the gouge, to ensure the entire removal of all necrosed portions, the wound was filled with lint, that it might granulate from the bottom.

There is a plan adopted at this hospital for the conveyance of the patients from the operating table to their beds, which, since it is not adopted in all hospitals, and is not perhaps generally known, we consider most worthy of being brought forward before the Profession at large. The table is covered with a folded blanket, upon which may or may not be placed a mattrass: a strong waterproof canvas sheet, having the edges of its sides turned under, and so stitched as to leave a space running along their entire length, is put immediately under the patient, and retained during the entire of the operation. When the person is to be carried away, a stout pole is run along the lateral space formed on each side by the turning under of the edges of the mackintosh sheeting, and then the poles being secured to each other by cross pieces of iron, are taken hold of by bearers, and the entire carried after the fashion of a stretcher.

There is very little disturbance of the patient.

To this contrivance has been just added a most convenient kind of hospital carriage, upon which the patient, lifted on the mackintosh sheet off the operation table, can be laid and wheeled noiselessly out of the theatre to the "lift."

ILLNESS OF MR. HODGSON.—It is stated that the health of Mr. Hodgson, the Senior Vice-President of the Royal College of Surgeons, is in so precarious a state as to prevent his attendance at the examinations now going on, much to the regret of many gentlemen so anxious to have his autograph to their diplomas.

MIDDLESEX HOSPITAL.

CASE OF POLYPUS UTERI.

(Under the care of DR. HALL DAVIS.)

R. G., æt. forty-eight, single; by occupation a dressmaker. Admitted August 24th, 1863.

Description.—She is tall, naturally thin and bony; the features are large and masculine; hair brownish grey; eyes grey; manner quick and impulsive.

Family History.—Her father died twenty years ago from the effects of a fright; her mother died four years since from a combination of diseases—namely, bronchitis, morbus cordis, and ascites. There are four sisters at present alive, and all in good health; there are also three brothers living, three having died.

Previous History.—She has always enjoyed moderate health, except on one occasion, when she was laid up with rheumatism. The catamenia appeared at the age of nineteen in the regular manner, and unattended with any unusual amount of pain, and have continued so up to about a year since, when she fancied the change of life took place; but at the expiration of six months, spent abroad, the monthly discharge returned at irregular intervals. Three years ago, found that the discharge increased, both at the periods, and also at irregular intervals, for which she has been under medical treatment more or less constantly up to the present time.

Acting upon the advice of Mr. Nunn, by whom she was seen, she sought and obtained admission into the hospital, in order that she might have removed a polypoid tumour, which was lying in the vagina, and passing up by a pedicle into the uterus.

State on Admission.—There is a polypoid tumour suspended from the cavity of the uterus, and falling into it; it lies in the vaginal canal; a fibroid enlargement can be felt on the upper part of the vagina, on the left side of it, and encroaching somewhat anteriorly; it is probably attached to the uterus externally; there has been a constant sanious discharge from the womb for the last three weeks, nor has it been limited to this short period, for it has been more or less present for the last three years.

August 24th.—Ordered ordinary diet, and porter, Oss.

25th.—A polypus about the size of a pigeon's egg, but longer and flatter, was removed by excision; a purchase was obtained upon it by means of a forceps; hæmorrhage was very slight.

℞ Mist. camph., ℥j.
bis in die.
Ale, Oss., *vice* the porter.

27th.—Since the operation, the patient has been very comfortable until this morning, when she noticed the discharge was somewhat increased; but it seems disposed to again diminish, or to disappear altogether.

10 a.m.—Haust. sennæ co., ℥j. Statim.

℞ Plumbi diacet., gr. iv.;
Pulv. opii, gr. ss. Ft. pil., hâc nocte.

28th.—Fill (?) has produced vomiting; there are now present constant nausea and pain in the right hypochondriac region; the matter vomited is of a dark-brown colour, and is mixed with a clear liquid.

Ordered Haustus magnesiæ co., ℥jss. Statim.

7 p.m.—The vomiting, which was checked by the draught, has returned and is of a peculiar yellow-green tint.

29th, 8.30 a.m.—Nurse reported that the patient had been vomiting since 5 a.m., and that the vomiting was accompanied with acute, almost spasmodic, pains over the region of the liver, and extending across to the epigastrium.

The patient was found with anxious countenance; cool, almost cold, skin; constant nausea, with occasional vomiting; and the spasm almost becoming tetanic in the mode of seizure and continuance. Pulse is 98 to 100; soft, easy, and compressible.

Ordered to have some ice to suck, and to have turpentine fomentations to the abdomen.

℞ Bismuthi trisnitratis, gr. v.;
Magnesiæ carb., gr. iv.;
Acidi hydrocyanici dil., ℥ijss.
Ex aquâ. Quartâ quâque horâ.

Diet, simple, with some beef-tea for to-day, and one pint of milk.

2.30.—Vomiting has not been checked, except in frequency; the same amount of matter has been thrown up, as have also both the draughts; the spasms are still very severe, the pain is also very acute; bowels have not been opened since yesterday; tongue is white, but moist.

℞ Oxalat. cerii, gr. j., in pil., ter die.

Cataplasm lini c. terebinth to the abdomen. Ice to suck.

℞ Spts. eth. chlor., ℥x.;
Tinct. camph. co., ʒij.;
Aq. menth. pip., ʒj.
Statim et rep. quartâ quâque horâ.

℞ Liquor calcis, Oss., c. Lacte.

11.30.—Vomiting has ceased; patient has had a refreshing sleep, and is much improved.

30th.—Has had a good night; no vomiting; slight spasmodic pain at intervals, but it has not assumed the grave character that it did yesterday; tongue is disposed to clean; bowels have not been opened.

Omit pil., et cataplasm lini, et ice; repet. haust. et liq. calcis.

31st.—Has had a very fair night, and continues better today; no vomiting; occasional pain in the side.

September 1st.—Continues much the same; no action of the bowels. Ordered, haustus sennæ co., ʒj. Statim.

℞ Spts. eth. chlor., ℥x.;
Mist. camph. et aq. menth. pip., aā ʒvj. Ft. haust.
Continue liq. calcis

She is to have ordinary diet, and of milk, Oj., as extra.

4th.—Is quite convalescent, and in most excellent spirits.

℞ Haust. quinæ co., ʒj., ter die.
Port wine, ʒij.; ale, Oss.

She is most decidedly better, but looks weak; pulse is 82; tongue is flabby and pale. Ordered—

℞ Ammon. ferri citratis, gr. v.;
Infusi quassiæ, ʒj.;
Spts. menth. pip., ℥xx., ter die.
Brandy, ʒij.

11th.—Seems very much better, though she is still weak. 14th.—Discharged convalescent.

MANSLAUGHTER BY A HERBALIST.—Mr. Humphreys, the coroner for Middlesex, has recently held an inquest at Limehouse as to the death of William Proby, aged fifteen years. It appeared that at the beginning of March he was taken ill, and a Mr. John Stevens, a herbalist, was called in, who said that the deceased was suffering from fever, and prescribed a powder and some pills. As he became worse, Dr. Cumming was sent for, who said the boy was suffering from a diseased hip; but the treatment of Stevens was preferred, and after enduring great agony with the hip the boy died. Mr. F. J. Gant, of the Royal Free Hospital, who had made a post-mortem examination, deposed that he found all the internal organs healthy; the intestines were congested; the left hip showed inflammation of some duration, and the cartilages of the joint had been absorbed. Death had arisen from exhaustion, caused by great pain consequent upon neglect of the diseased hip. Dr. Letheby, Professor of Chemistry at the London Hospital, said that he had examined the stomach and found great inflammation Upon testing the medicine he found it to be composed principally of cayenne pepper. The evidence of both these gentlemen proved that this medicine had caused great irritation and pain, with subsequent vomiting and exhaustion, and, added to the pain of the hip, finally produced death. In support of the treatment adopted by Mr. Stevens, Dr. J. A. Coffin, of Montague street, Russell square, asserted that cayenne pepper was the proper remedy to be administered. The jury returned a verdict of manslaughter against Mr. Stevens, who was fully committed.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XIII.

ALUMEN.—Alum, in this country, is principally manufactured from aluminous schist or shale. This mineral varies somewhat in its composition and characters; but it always contains alumina and bisulphide of iron or pyrites, and some carboniferous matter. In some localities it also contains a salt of potash. Some varieties of this shale, when simply exposed to the action of air and moisture, absorb oxygen, gradually disintegrate, and ultimately yield an efflorescent mass of sulphate of alumina and iron. The oxygen unites with the sulphur of the pyrites, forming sulphuric acid, and also with the iron to form oxide of iron. The acid then uniting partly with the alumina and partly with the oxide of iron produces a kind of double salt, which in effloresing out, breaks up the surface of the stone. In other cases it is necessary to assist the action by piling the stone in heaps and burning it by the aid of a slow fire. When, by either plan, the oxidation is completed, then the mass is lixiviated with water, whereby a solution of the soluble sulphate is obtained. The resulting liquor is concentrated by evaporation and allowed to cool, when some of the sulphate of iron crystallises out. To the mother liquor, which contains the sulphate of alumina and some sulphate of iron, together with several impurities, is then added the salt of potash, and the alum is obtained by crystallisation. Chloride of potassium is the salt generally employed, on account of its cheapness. When added to the liquor it undergoes decomposition with the sulphate of iron, forming chloride of iron and sulphate of potash. The latter salt uniting with the sulphate of alumina and with water forms the alum, which separates out. The chloride of iron is very soluble and remains in solution. Latterly, however, ammonia has been to a great extent substituted for the potash in alum, the crude sulphate or chloride of ammonium got from the gas liquors being used in place of the chloride of potassium.

Alum is also manufactured to some extent from clay. The clay, consisting of a silicate of alumina, is heated with sulphuric acid, whereby a sulphate of alumina is obtained. This, when treated with a salt of potash or ammonia, furnishes an alum.

Alum occurs ready formed in nature in certain volcanic districts. Its formation is obviously due to a similar action to that which occurs in alum schist. Alum crystallises in large and very regular octahedrons. It consists of a double sulphate of alumina and potash, combined with twenty four atoms of water. The term alum is now, however, used by chemists in almost a generic sense, being applied to a large group of isomorphous compounds. It is found

that the aluminium in common alum may be replaced by certain other metals, such as iron, chromium, and manganese; that the potassium may also be substituted by sodium and ammonium; and that these changes may be effected without, in the slightest degree, altering the crystalline form of the salt, or affecting its general properties. In each case the numerical relation of atoms building up the molecule of the salt remains the same. With the metals above-named we may thus have twelve salts, each differing from the other in the elements present, but all resembling each other in every other respect. Each of these salts, therefore, is an alum.

The alum ordered by the British Pharmacopœia is a sulphate of alumina and potash. It will not be found, however, always easy to obtain potash alum in commerce, ammonia alum having largely replaced it. We do not know of any reason for selecting potash alum to the exclusion of the other, unless it be that the Pharmacopœia authorities considered it better suited for making dried alum. Potash alum may be distinguished from either soda or ammonia alum by the employment of two tests. When heated with excess of strong potash, no smell of ammonia should be evolved. When dissolved in water and treated with a strong solution of tartaric acid, a crystalline precipitate should slowly form. The most frequent impurity in commercial alum is iron. It may be detected, as the Pharmacopœia directs, by adding to a solution of the salt a mixture of the ferrocyanide and the ferridcyanide of potassium. Its presence may also be at once recognised by tincture of galls.

AMMONIÆ ACETATIS LIQUOR. This preparation has suffered considerably by its introduction into the British Pharmacopœia. Previously, Mindererus's spirit was invariably prepared by saturating the dilute acetic acid with sesquicarbonate of ammonia. Under these circumstances a solution of acetate of ammonia was obtained, which was *saturated with carbonic acid gas*. The presence of this gas gave to the liquor its sparkling, pleasing character. The Dublin Pharmacopœia specially directed that the saturation should be effected in the cold, thereby indicating that the presence of the carbonic acid was considered to be of importance. The last Edinburgh Pharmacopœia, and previous editions of the London Pharmacopœia also, ordered this preparation to be made with distilled vinegar, instead of dilute acetic acid. A more palatable, and, therefore, more agreeable medicine was thus produced.

The apparent tendency now, however, is to produce medicines of a definite chemical composition; to regard, in fact, their chemical formulæ as of equal importance to their medicinal qualities. Thus, in the Materia Medica of the British Pharmacopœia, liquor ammoniæ acetatis is described as "acetate of ammonia, $N H_4 O, C_4 H_3 O_3$, dissolved in water." We cannot resist the idea that the process given among the preparations was devised, rather in accordance with the above description, than from any consideration of what would be most agreeable to the patient. The dissolved carbonic acid could not well be expressed in the chemical formula given; it was therefore omitted from the preparation. The process, as it stands, consists simply in neutralizing acetic acid with strong solution of ammonia. Undoubtedly the product is chemically more definite; but it is vapid to the taste, and a disagreeable thing in comparison to the old liquor. The skill of the pharmaceutist is displayed in the production of medicines in the best and most pleasing form; but in this instance the art of pharmacy has been sacrificed to the science of chemistry.

The liquor of the British Pharmacopœia has a sp. gr. 1·06. It contains five times as much acetate of ammonia as the liquor of the London College, and six times as much as that of the Dublin and Edinburgh Colleges.

AMMONIÆ BENZOAS.—The Pharmacopœia directs benzoate of ammonia to be made by dissolving benzoic acid in dilute ammonia, evaporating at a gentle heat, and setting aside that crystals may form. Benzoic acid forms two salts with ammonia—an acid benzoate, and a neutral benzoate. In evaporating a solution of the neutral salt, a portion of the ammonia escapes, and the acid benzoate is formed. It is necessary, therefore, to preserve a slight excess of ammonia in the liquid throughout the process, in order to obtain crystals of the neutral benzoate of ammonia. Benzoate of ammonia occurs in colourless plates; is extremely soluble in water and in alcohol; it sublimes when heated; and its solution gives a bulky, yellow precipitate with a persalt of iron.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Under the head of "Abstracts of Clinical Lectures in Surgery," Mr. CHARLES H. MOORE relates a curious case of "Periodical Inflammation of the Knee-Joint." The patient was a woman who had suffered from ague at the age of eighteen, and eight years after the cessation of the ague she experienced a swelling of the knee-joint, accompanied with pain. This affection, however, lasted only three days, and she remained well until thirty days after the attack, when it was repeated, lasted the same time, and then left her well. The inflammatory swelling recurred for a considerable time at regular intervals of a month, but afterwards at shorter intervals, and the periods were partially suspended by pregnancy and lactation. On the supposition that the attacks were in some measure connected with ague, Mr. Moore ordered quinine, with some success, for this drug delayed the period of the attack but did not prevent its occurrence; and arsenic was subsequently prescribed, without any success at all, and the patient finally ceased to attend and was lost sight of.——Dr. JOHN COCKLE offers some "Clinical Illustrations of Abdominal Aneurism," and relates the particulars of three cases of this affection. In one of them, in which the symptoms during life were very obscure and were complicated with other diseases, it was found that an aneurism of the inferior mesenteric artery had burst into the intestine, which latter had formed the anterior covering of the aneurismal sac.——Mr. HANCOCK continues his papers on "Division of the Ciliary Muscle,"

and relates two cases in which this operation was successful, and also states that he has heard from an oculist at Bombay, that the operation has been performed there at least fifty times in three months, with great success, in cases of acute and chronic keratitis, irido-choroiditis, and sub-acute and acute glaucoma.

THE 'MEDICAL TIMES AND GAZETTE.'

PROFESSOR HELMHOLTZ continues his lectures "On the Conservation of Energy," his present subject being the influence of heat upon the processes going on upon the surface of our globe.——Dr. HARLEY continues his lectures "On the Urine, and Diseases of the Urinary Organs," his present subject being uræmia, including uræmic poisoning, and the method of estimating the amount of urea. The remedies which diminish the elimination of urea are, citrate of quinine and iron, digitalis, benzoic acid, acetate and phosphate of soda, and colchicum. Those which increase it are cubebs and cantharides, and atropine. The urea is also diminished by starchy foods and sugar, and oils or fatty matters, and it is increased by animal soups, eggs, milk, jellies, or other nitrogenized substances, with a fair portion of common salt, and coffee, but without sugar.—— Mr. J. L. LAURENCE continues his papers "On the Optical Defects of the Eye," his present communication being devoted to optical considerations, and the effects produced by viewing objects through lenses.——Dr. J. W. OGLE communicates a series of "Cases of Softening of the Brain and Spinal Cord," the symptoms during life being recorded, as well as the appearances observed after death.——Mr. E. E. DAY relates "A Case of Typhoid Fever in Connexion with Pregnancy," the patient being confined of a dead child, but eventually recovering.——Mr. F. A. BULLEY, in some clinical notes and observations, relates a short case of "Contraction and Thickening of the Palmar Fascia and Permanent Flexure of the Fingers."

THE OPHTHALMIC REVIEW: A QUARTERLY JOURNAL OF OPHTHALMIC SURGERY AND SCIENCE. Edited by J. Zachariah Laurence and Thomas Windsor. London: Hardwicke. April, 1864.

In a short introduction, the editors of this review explain their reasons for its production, and the principles on which they intend to conduct it. They consider that the advanced condition of ophthalmic surgery in Great Britain and the Continent of Europe, justifies the attempt to establish a journal exclusively devoted to this subject, and which takes for its model some periodical works of the same nature published in France and Germany. The journal will comprise original papers on ophthalmology, and translations of the more important foreign contributions which appear from time to time, and a quarterly digest of the principal British and Foreign ophthalmic productions, together with reviews and critical analyses of works, memoirs, papers, &c., published in Great Britain, Germany, Holland, France, and Italy. The present number contains a translation of a paper on the "Form of Cataract Knives," by Professor Zehender, of Bern, another by Professor Von Gräfe on the "Calabar Bean," and a third on "Retinitis Pigmentosa," by Dr. A. Mooren; and original papers on "Iridectomy," by Mr. Windsor, and on "Paralysis of Accommodation, Treated by the Calabar Bean," by Mr. Moon. The reviews of the English ophthalmoscopic literature are marked by great ability and acuteness, but are very truculent in their character; while the retrospect of British and Foreign ophthalmic literature displays extensive research on the part of Mr. Windsor.

REVIEW OF BOOKS.

On Diseases of Women. By Fleetwood Churchill, M.D., M.R.I.A. Fifth Edition, pp. 937. Dublin: Fannin and Co. 1864.

Dr. Churchill's Treatise on the Diseases of Women is too well known to require a detailed analysis of its contents, and the great reputation and large experience of the writer are so generally recognised, that anything emanating from his pen must command general attention and respect. The distinguishing characters of this treatise are the copious extracts made from the experience of other authors on the same subject, with ample reference to the published works of each, and the matured views of Dr. Churchill himself, who has long and successfully laboured in the field of obstetric medicine. The reader, therefore, who consults the pages of this work will find, in the first place, a digest of all the existing medical literature bearing upon the Diseases of Women; in the second place, the practical views and suggestions of Dr. Churchill himself, which are, necessarily, of the highest value; and thirdly, he will find illustrative engravings (not very numerous, but very good of their kind) of various forms of uterine or other peculiarly female diseases, and of instruments devised for their detection or their relief. As each successive edition of the work has made its appearance, Dr. Churchill has expanded or corrected the matter in accordance with his extended experience, or the progress of science; and thus it is brought up to the standard of the present day. It is only to be regretted, in so valuable a book, which is said, in the title-page of the present edition, to be "carefully revised" as well as enlarged, that many typographical errors have been allowed to escape notice; and these certainly detract somewhat from its value. They are, however, so obviously the result of mere inadvertence, perhaps resulting from the numerous professional avocations of the author, that they are to be regretted rather than censured, and cannot really mislead any intelligent reader. Still, we should advise Dr. Churchill to subject the book to careful supervision in the event of another edition being required.

The Prescriber's Companion. By Alfred Meadows, M.D., M.R.C.P. Pp. 152. Renshaw, London, 1864.

Dr. Meadows states in his preface that he has compiled this work in order to help the Profession to understand the changes introduced into the Pharmacopœia. He has, however, not confined himself to the substances included in that work, but has comprised many preparations which are not pharmacopœial, but which experience has proved to be valuable. He has also classified all the substances according to their physiological action, a plan possessing some advantages, but open to many objections, which it is unnecessary to enumerate. This little work has certain merits, and may perhaps be found useful in some respects; but we are sorry to observe that it is full of grammatical and typographical errors, which might have been avoided by moderate care. To take some almost at random, we find, Enema *Colocynthis* (p. 2), *Ammoniæ* Bromidum (p. 25), *Ammoniæ* Iodidum (p. 26), *Lithia* Carbonas (p. 27), *Lithia* Citras (p. 28), *Potassæ* Bromidum (p. 29), *Potassii* Sulphurata (p. 31), Sodii *Iodidi* efferverscens (p. 33), *Aconitium* (p. 42), Arseniosum (?) (p. 75), Potassii *Iodidi* (p. 114), Ricini communis *foliæ* (p. 114), *Aloes Socotrinæ* (p. 114), Croton *Tiglii* (p. 128), Juniperus *Sabinæ* (p. 129), *Potassium*

Bromidum and *Potassium* Iodidum (p. 135), Rubia *tinctorium* (p. 135), Ferri *Sesquichloridi* (p. 136). With such a multitude of mistakes we cannot very strongly recommend this book, especially to young practitioners and to students, who are too apt already to make slips in their grammar, and to confound one chemical termination with another.

Notes on the British Pharmacopœia; showing the Additions, Omissions, Change of Nomenclature, and Alterations in the various Compound Preparations, with the Doses of those Medicines which are Comparatively New. By A. F. Haselden, Pharmaceutical Chemist. Pp. 82. London: Hardwicke, 1864.

The British Pharmacopœia being intended to reconcile the discrepancies hitherto existing between the London, Dublin, and Edinburgh works, it has, of course, entailed much labour upon its compilers, and hardly less upon its readers. Hence the necessity of books like that of Mr. Haselden, showing us the additions and omissions made, as compared with the former Pharmacopœia, and the changes of name and of composition of the preparations and compounds introduced into the recently published Pharmacopœia. Mr. Haselden's little book appears peculiarly well adapted to meet the wants of the pharmaceutists, who are necessarily obliged to keep a great variety of drugs to suit the exigencies of English, Scotch, and Irish prescribers, and to the chemists and druggists, therefore, all changes of nomenclature or of chemical composition should be distinctly made known. Mr. Haselden has done his work well; his descriptions are very clear, and his terminations are chemically as well as grammatically correct.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.
